
The still described (see fig.) has proved very efficient for fractional distillation and allows of the determinatior of the exact boiling points of the fractions. It consist of a flask with sid tube, parallel to th neck of the flask attached to it by tw connecting tubes, th lower one being ben so as to minimise th amount of dead spac capable of retainin the liquid being distilled. The side tub is constricted at th top where it receive and holds closely th shell of a Beckman thermometer near th zero mark; with hy groscopie liquids, th thermometer must b fitted in place wit a ground joint. . mirror of tinfoil t prevent radiation preferably boun around the side tub so as to surround th bulb of the therm meter, and the who of the side tube ar the upper connectin tube is encased in thick shell of asbesto In an experiment wi 500 c.c. of commerci toluene, after si distillations, with s fractions eac time, 130 c.c. of liquid distilling within an interv of 0·02° C. were obtained, and two more fra tionations of 65 c.c. of this liquid yielded 40 c.c. of tolue distilling within a range of less than 0·01° C. By imme ate immersion of the warm dry bulb of the standardis Beckmann thermometer into a steam bath, the differen between the boiling points of the toluene and of water w measured. A slightly modified form of the still for t with a small Anschütz thermometer is also described.

Nitrogen [in urine, etc.]; Colorimetric determination total ——. A. Gulick. J. Biol. Chem., 1914, **18**, 541 547.

A weighed quantity of the substance (or 1 to 2 c.c. urine), containing about 7 mgrms. of nitrogen, is treate in a flask of about 50 c.c. capacity, with 1 c.c. of sulphu acid, 1 grm. of potassium sulphate and 3 drops of saturated mercuric chloride solution, and the mixt is heated until oxidation is complete as in the ordina Kjeldahl method. The solution is then cooled, dilu to 100 c.c. with ammonia-free water, and the ammon content determined directly by Nessler's reagent. latter should be prepared by dissolving mercuric iodi 15, potassium iodide, 10, and sodium hydroxide, 40 grm in 500 c.c. of ammonia-free water.—W. P. S.

Carbon monoxide; Determination of ——. J. I. Grah and T. F. Winmill. Chem. Soc. Trans., 1914, **105**, 199 2003.

A modified form of the Haldane apparatus is used. measured gas sample is first treated with bromine potassium bromide solution, followed by potash;

es in volume gives the carbon dioxide, hydrogen sulhide, sulphur dioxide, and unsaturated hydrocarbons. ; is then passed backwards and forwards, by means of the otassium hydroxide solution confining it, through a tube filled completely with powdered iodine pentoxide reviously heated for 3—4 hours in a current of dry air at 0° C. Before and after this operation the U-tube stands cold water of known temperature; during the passage of e gas in water at 90°—100° C. The loss in volume gives e carbon monoxide. Mixtures rich in hydrogen and rbon monoxide require dilution with air to bring the ydrogen below 20% and the carbon monoxide below 8%: herwise hydrogen is oxidised. An accuracy of 0·02% possible.—O. Trade Report.

Contraband of War.

A Royal Proclamation, dated September 21st, 1914, adds the following to the list of articles to be treated as "conditional contraband":—Copper, unwrought. Lead, pig, sheet, or pipe. Glycerin. Ferrochrome. Hæmatite iron ore. Magnetic iron ore. Rubber. Hides and skins, raw or rough tanned (not including dressed leather).

Competition with Germany and Austria-Hungary. Further list of articles in connection with which applications have been received at the Board of Trade. September, 1914.

The following is extracted from a second list which has been issued by the Board of Trade to supplement the list issued in August (see this J., 1914, 896); those interested should communicate with the Commercial Intelligence Branch, Board of Trade, 73, Basinghall Street, E.C..

A.—*Articles which inquirers wish to buy.*—Acetates; acetic anhydride; acetone; alum blocks; aluminium silicofluoride; ammonium persulphate, silicofluoride, and sulphate; aniline oils; arsenic and its ores; bakelite; barium and its ores; barium carbonate, chlorate, peroxide, and sulphate; barytes; beryllium; benzene; bleach, liquid; bitumen for flash lamps; borax; cadmium; calamine; candles; carbonic acid gas; cerium nitrate; chemicals for brass engraving and for laboratories; chlorophyll; chrome alum; chromium and its ores; chromium oxide, pure; Chinese wood oil; clay; cocoa butter; copra; cryolite; diatomite; ethyl-acet-trichloranilide; felspar; filter paper; filters; fireworks; fluorspar; formic acid; fossil earth; galalith; glass, chemical and philosophical, blown; soda glass for Crookes' tubes; optical glass; glue for bookbinders; gum tragacanth; hydrochloric acid; hydrogen peroxide; kieselguhr; kainite; lactose; lampblack; lanoline; lead, pig and powdered; lead sulphate and hypophosphite, white lead; leather, artificial; limestone; lithopone; magnesium; manganese oxide; mannol; mannol ethyl ketone; matches, safety; methyl-ethyl-ketone; mineral jelly; mineral oils, white, and refined for foods; molybdenum; naphtha; oils for motors and for soap-making; oxalic acid and oxalates; petroleum, white toilet; photographic papers and chemicals; platinum ores; potassium bromide, chloride, metabisulphite, and persulphate; porcelain, chemical; potato flour; pyrogallic acid; quartz; resorcin; rubber, synthetic; salicylic acid; selenium; size (Sickel); slag, basic; sodium hyposulphate, peroxide, and salicylate; strammonium herb; superphosphates; tannin; tanning materials; tartaric acid and tartrates; thorium nitrate; tin oxide; tungsten and its ores; urea; vanadium ores; vanillin; vegetable extracts; washing blue; waterproofing paste and solution; wood distilling plant; wood tar; wood pulp; wool fat, purified; zinc blende and spelter; zinc sulphide and other compounds.

B.—*Articles which inquirers desire to sell.*—Acetates; albumin; alloys, special; aluminium; asbestos; baking powder; bottles; bronze powder; carbolic acid; carbonates; celluloid and celluloid articles; cellulose; charcoal; chlorides; coal and fuel; cresylic acid; explosives; filters; French chalk; galalith; gelatin; glycerin; malt extract; metal foil; mica; ores and minerals; oxides; plaster, wall and ceiling; plastic compositions; rubber; rubber goods; soap; starch; sugar; sulphates; sulphides; tannin; tar; tin; tungsten; waterproofing paste.

Competition with Germany and Austria-Hungary in neutral markets.

In pursuance of the Board of Trade Scheme for assisting British manufacturers and traders to secure trade in British Possessions and foreign countries (see this J., Sept. 15th. 1914, p. 896), bulletins have been issued on lubricating oils and greases; boot polishes; rubber tyres for motor cars and motor cycles; goldsmiths' and silversmiths' wares and electro-plate; fertilisers; perfumes and cosmetics; medicines and drugs.

Openings for British trade. Board of Trade J., Sept. 10, 1914.

Canada.

A firm in Montreal would take up agencies for dyes and chemicals suitable for factories making cotton goods, paper, and matches. (C.I.B. 24207.)

A firm of manufacturing chemists in Toronto wishes to represent manufacturers of pharmaceutical products not conflicting with its own goods, a catalogue of which may be seen at 73, Basinghall Street, E.C. (C.I.B. 24219.)

A hardware company in the province of Ontario requires sodium cyanide, 98—100% and 128—130%; quicksilver; sodium sulphide; glassware similar to "Jena"; porcelain ware and various assay and chemical apparatus such as is used in silver, gold, and nickel mines. (C.I.B. 24223.)

A Montreal company invites offers for tungsten lamps of 10, 15, 25, 40, 60, 100, 150 and 250 watts in 110 and 115 volts. Lamps should be made of continuous drawn wire tungsten with screw sockets suitable for the Canadian market. (C.I.B. 24224.)

A manufacturer's agent at Montreal wishes to secure agencies for chemicals and oils.

A Toronto company desires supplies of rubber articles.

Further information as to the above may be obtained at 73, Basinghall Street.

England.

The following home enquiries have been received at 73, Basinghall Street, whence further information may be obtained :—

A London company needs supplies of wood naphtha, acetic acid, acetone, methyl alcohol and formaldehyde and invites Canadian offers.

Others desire the addresses of Canadian graphite mines, and of Canadian manufacturers of bronze powders.

Holland.

A gold-mining company, with offices at the Hague and mines in Java, wants quotations for two tons of cheap commercial calcined borax, and for zinc discs.—Apply, 73, Basinghall Street, E.C.

Italy.

The British Chamber of Commerce at Milan has received enquiries from local firms, who want the following goods: tanned leathers, leather goods, hides and skins, glass tubes and gauges, wood pulp, oilskins, dyeing and bleaching materials, chemicals, iron and steel, and indigo.

Japan.

Stocks of dyes in Japan are sufficient for six months' requirements.

Sweden.

A firm of importers wishes to buy menthol, crystallised and double crystallised.—Address, Swedish Chamber of Commerce, 5, Lloyd's Avenue, E.C.

Canadian import duties on certain articles increased. Board of Trade J., Sept. 10, 1914.

A Customs Memorandum (No. 1811b) contains the text of a Canadian Act to amend the "Custom Tariff Act, 1907," which received assent on Aug. 20, 1914. It increases the rates of duty on various articles imported into Canada, among them being sugar, preserves, ale and stout, fruit juices, ethyl and methyl alcohol, perfumes, nitrous ether, sweet spirits of nitre, aromatic spirits of ammonia, medicated wines, malt extract, all medical, chemical, and pharmaceutical preparations compounded of more than one substance, patent and proprietary preparations, and paints, colours, lacquers and varnishes.

Books Received.

The Inventor's Handbook of Patent Law and Practice. By Francis E. Bradley, LL.D., M.A., etc., and F. H. Bowman, D.Sc. Ewart, Seymour & Co., Ltd., Windsor House, Kingsway, London, W.C. 1914. Price 5s.

Volume (8¾ ins. by 5¾ ins.), containing 173 pages of subject-matter, including an appendix, and followed by a list, I. to XIV., of Law Officers' Rules, and an alphabetical index of subjects. The matter is classified as follows:— I. Origin and history of Patent Law and Procedure. II. The patentee and the subject-matter of a patent. III. How to preserve the inventor's rights before the patent has been granted. IV. How to obtain a patent. V. Oppositio to grant of patent and the inventor's method of defence. VI. Revocation of a patent. VII. Register, rectificatio of register, licences, and assignments. VIII. Means o exploiting a patent so as to render it profitable. IX Amendment of specification. X. Foreign and colonia patents. XI. Legal proceedings. XII. Miscellaneou provisions. Appendix. Patents and Designs Acts, 190 and 1908. Patents Rules of 1908.

Science and the Miller. By J. S. Remington. Th Northern Publishing Co., Ltd., 17, Goree Piazzas, Liverpool. 1914. Price 4s. 6d. net.

Volume (7¼ by 5 ins.) containing 166 pages of subjec matter and 8 plates and including chapters on: the trainin of the flour-mill chemist; oils and lubrication; purchas of coals and oil fuel; moisture in wheat and flour; in provers and enrichment processes; breakfast, invali and infant foods; feeding stuffs and mill offals.

Annual Statement of the Trade of the Unite Kingdom with Foreign Countries and Britis Possessions, 1913 Volume II. [Cd. 7585.] Pric 4s. 1d.

This volume contains abstract and detailed tables imports from, and exports to, each country; abstra and detailed tables of imports and exports at each port tables showing the amount of Customs revenue receiv at each port or place; details of the transhipments und bond of certain articles; an account of the quantities articles liable to Customs duties remaining in bond, an details of the transhipments of free goods on through bil of lading.

Patent Office Library; Subject Lists; New Serie Patent Office, 25, Southampton Buildings, W.C. Pri 6d. each.

Journal of the Society of Chemical Industry.

No. 19, Vol. XXXIII. OCTOBER 15, 1914. No. 19, Vol. XXXIII.

Official Notice.

APPOINTMENT OF NEW EDITOR.

The Council of the Society of Chemical Industry will shortly proceed to appoint an Editor of the Society's Journal in place of Mr. Watson Smith, who has resigned. The Editor will be required to devote his whole time to the duties of his office, and, subject to the Publication Committee, will be held responsible for the whole of the contents of the Journal, the necessary assistance being provided by the Society. Minimum Salary £500.

Applications for the appointment should be forwarded to the President at the office of the Society, Broadway Chambers, Westminster, S.W., before the 1st November, 1914.

Canadian Section.

Meeting held at Toronto on Friday, March 27th, 1914.

VISCOSE: A NEW CASING FOR SAUSAGES.

BY W. P. COHOE, E. C. FOX, AND A. J. ACTON.

Casings for sausage meats at present in use consist of the larger intestines of the ox, sheep, and hog, known in the trade as bungs; the gullet of the ox known as "Weasands," and the smaller and middle intestines of the ox. For small sausages the smaller intestines of the sheep and hog are used. They have been used for many generations. No exception can be taken to them providing proper precautions are taken to insure their purity.

In the large packing houses the conditions of purity are more closely watched than in small butcher shops and abattoirs, but a sanitary substitute is highly desirable.

An ideal casing should possess the following properties:

The raw material should be pure and uniform. The process of manufacture should not permit any possibility of contamination by disease germs. The finished product should be of uniform chemical composition. It should be mechanically suitable. It should have a pleasing physical appearance. It should not provide a surface upon which mould and other organisms can readily propagate. It should not contain substances injurious to the human organism. It should be, although in many cases not necessarily so, edible. If possible it should be digestible. It should be capable of being kept, stored and transported, under ordinary conditions, for an indefinite period of time, without deterioration.

So great has been the increase in the demand for sausage and Bologna, and so drastic of late has been the condemnation of natural casings by Government meat inspectors, that the cost of natural casings is very high and likely to remain so.

There is a certain sized casing for which there is a great demand. Artificial casings can be made in any quantity to this standard at a less cost than the natural casings.

In order to find a substitute for the present casings, a survey of the field of possible raw materials was made, and it was finally decided to try cellulose (hydrate) and to use the viscose reaction of Cross and Bevan.

Bleached sulphite wood pulp is used as the raw material. This is mercerised by the action of caustic soda solution, washed and treated by carbon disulphide.

On the addition of water swelling takes place, giving a thick viscous solution without a trace of fibrous structure. This material is then manufactured into tubes, and passed into a salt solution, which converts it into a yellow jelly. The by-products of the reaction are largely removed by washing in mixed solutions of sodium sulphides and bisulphites. Many of the salts may be removed by heat, either by the direct action of steam, or by passing the tube through a hot solution, either of salts, alcohol, glycerin, and many other substances.

The tube, which now consists of cellulose (hydrate) together with adhering sodium salts, is washed thoroughly in boiling water. The length of time necessary to accomplish this may be first determined by an ash determination. When the amount of ash falls to an amount equal to that in the original bleached sulphite pulp, freedom from impurities is assured. The tube is finally dried, conditioned, and rolled up ready for shipment.

Should colourless product be desired, the tube may be bleached after the hot wash. In this case it is led first through a hypochlorite solution, then washed in water, then led through thiosulphate solution, and finally washed in water.

At the present time containers of two sizes are being made, large sizes to replace beef bungs for the Beef Bologna trade and medium sizes in place of weasands for the Ham Bologna trade.

As soon as the necessary technical data can be obtained, it is proposed to prepare a small sized casing corresponding to the sheep or hog casings.

Bleached sulphite pulp is pure, abundant and uniform. The chemical treatment it undergoes ensures an aseptic condition. In cellulose (hydrate) we have a definite chemical compound, carrying with it slightly varying proportions of water. Inorganic impurities are limited to the small proportion of ash, 0·53% mainly consisting of alkalis and alkaline earths. The finished product contains less ash than the original wood pulp.

As the weight of a sausage casing of cellulose (hydrate) averages 1·04 to 1·12 per cent. of the meat, it may be seen that the ash present is insignificant. Still it is in the interests of careful manufacture to set a standard for this.

The experience in Canada with the use of the new product showed that its mechanical properties were satisfactory. Although the origin of the casing was known to the store managers, yet the man behind the counter, who had been handling sausages for years, did not recognise the change of material.

Cellulose (hydrate) casings are transparent and colourless in thin films when unbleached, and when bleached are colourless in all usual thickness. The surface is smooth and glossy, and does not easily afford a lodging place for mould or bacteria. Even supposing they do lodge there, such a surface does not furnish food for their growth. This is quite the opposite of the conditions characteristic of the casing hitherto in use. In the case of our product, we have something in the nature of a preservative coating or container. This is particularly true in the case of cooked sausages, where the casing dries rapidly.

Our product when finished contains: cellulose (hydrate), moisture, glycerin, and ash. The human organism is quite accustomed to cellulose in its varying forms in the ordinary diet. For instance, white cabbage contains 63·25% of cellulose. (Hoesslin; Z. Biol. 54, 395.)

For purposes of comparison it is interesting to note the proportions of fibre carried by various cereal products in common use.

Product.	Fibre.	Ash.	Authority.
Wheat flour (finest)	0·3	0·5	Konig
Wheat flour (American)	0·3	0·6	Johnson
Oat meat (American) ..	0·9	2·0	Johnson
Maize meal (American)	2·0	1·5	Johnson
Whole wheat flour	1·6	1·9	Richardson

There is a lack of uniformity between the results given by various authorities, due undoubtedly to the method used by the older investigators in determining "crude fibre." This error is very large. As much as 39% of the weight of sawdust can be hydrolysed by 1% hydrochloric acid under certain conditions. (See also Krauch and Becko, Landw., Vers. Stat., 27, 5; Cross and Bevan, this J., 1903, pp. 165 *et seq.*) Variations of method probably account for such results as are shown below.

Average composition of flour of cereals.

Cereal.	Cellulose.	Ash.
Old wheat	8·3	1·6
Barley	11·5	2·8
Oats	1·0	2·2
Rye	6·4	1·8
Maize	14·9	1·6
Rice	0·2	0·9

Taking the mean content of 1·8% of cellulose in American wheat, obtained by Richardson. after 407 analyses (Am. 6. 302) and remembering that the casing of a sausage is from 1·04 to 1·12% of its total weight, it will be seen that the eating of many of the prepared breakfast foods made from whole wheat, *e.g.* shredded wheat biscuit, involves a larger percentage of cellulose than does the eating of a sausage with cellulose (hydrate) casing.

Furthermore, it can be shown that cellulose (hydrate) is in a form more susceptible of chemical attack than is the hard covering of the cereal grains. To confirm this last point, bleached sulphite wood pulp and cellulose (hydrate) casing were treated side by side at 100° C. with first 0·50% hydrochloric acid, and secondly with 0·50% sodium hydroxide solution. The results were as follows :—

	Pulp.	Casing.
Dry weight	1·7678	1·6258
Weight after 5h. acid treatment ..	1·6468	1·3848
Weight after 4h. alkali treatment..	1·2278	0·8114
Percentage dissolved in acid	6·74	14·82
Percentage dissolved in alkali	23·80	35·27
Total percentage dissolved	30·54	50·09

Thus cellulose (hydrate) is more easily attacked than normal cellulose and cannot be looked upon as harmful. The ash content of our product, 0·53%, is so small that it may be neglected

Edibility is demanded only in the case of small sausages, the casings of which consist of intestines of the sheep or hog. The casings of sausages of the Bologna variety cannot be masticated in any reasonable length of time, and are simply coverings or food containers. The meat of the sausage also does not adhere to the casing when made of our product, as it does to the old ones. A Bologna casing made of cellulose (hydrate) can, however, be masticated. In such a case, a soft non-irritant mass is produced. In the case of the smaller sausages, the thickness of the casing is very small (0·004 to 0·006 in.).

The power of the human organism to digest cellulose is still a moot point among chemists. Much work has been done in the study of its value to the ox and the horse. It is only recently that exact information has been obtained with regard to man. For instance, Hammersten (Mandel's translation, pp. 291 and 297) states that certain kinds of cellulose are undoubtedly partly dissolved in the intestines and cites Hanneberg and Stohmann, Zeits. f. Biol. 21, 613; Kneirman. *ibid.* p. 67; Hofmeister, Arch. f. wiss. u. pract. Thier., 11; Weiske, Lat. f. Biol. 22, 373; Tappeiner, brd. 20, 24; and Mallovre, Pfflugers Arch., 49.

The most recent work on this subject, which has come to the writer's attention, is that of Lohrisch (Zeit. Ex. Path., 5, 478). The conclusion of this investigation is that in normal individuals 50% of cellulose is digested, and in chronically constipated cases 80%. The action is one of hydrolysis to sugar and starch. The suggestion of Lohrisch to substitute cellulose for sugar in the diet of diabetic patients is interesting. It would seem safe to conclude, therefore, that our product is at least in part digestible by the human system.

As our product consists practically of dried cellulose, its keeping properties are excellent. Under ordinary conditions of storage, it is not attacked by anything, but will keep indefinitely like paper or cotton cloth.

Yorkshire Section.

Meeting held at Bradford Midland Hotel, on Monday, May 11th, 1914.

MR. GEORGE WARD IN THE CHAIR.

ESTIMATION OF ALDOSES. (PART I.). THE ACTION OF NEUTRAL SODIUM HYPOIODITE.

BY N. BLAND AND L. L. LLOYD.

Since concordant results by polariscopic and copper methods for the estimation of sugars, dextrins, etc., in sizing mixures are difficult to obtain, an attempt was made to discover a method that would give some idea of the relative amounts of different sugars in mixtures. This work led to an examination of the oxidation of aldehydes by sodium hypoiodite.

The action of sodium hypoiodite upon formaldehyde was first tested. The reaction is quantitative according to the following equation :—

$$I_2+2NaOH=NaIO+NaI+H_2O$$
$$NaIO+HCHO=NaI+HCOOH$$
$$\text{or } HCHO+I_2+H_2O=2HI+HCOOH$$

The hypoiodite may be used for the estimation of formaldehyde as follows :—5 c.c. of commercial formaldehyde ar diluted to 1000 c.c. and 10 c.c. of this solution are adde to 50 c.c. $N/10$ iodine to which a slight excess of causti soda has been added. The reaction mixture is allowed t stand for about five minutes, acidified with dilute hydro chloric or sulphuric acid, and the liberated iodine titrate with $N/10$ thiosulphate. Each c.c. of iodine used repre sents 3% of formaldehyde. In one experiment a figur of 40·5% was obtained. The results are concordant an quite as accurate as the longer process in which the amoun of ammonia to form hexamethylenetetramine is foun by adding to a solution of the formaldehyde, ammoniu chloride, followed by a definite quantity of $2N$ causti soda, allowing to stand in a stoppered bottle for abou two hours and titrating with standard acid, using meth orange as indicator. The formaldehyde gave by th hexamethylenetetramine method 40·3 and 40·5%, compared with 40·5% by the hypoiodite method.

An attempt to value paraformaldehyde by this metho failed. The paraformaldehyde was in a finely divid condition, and gave very variable results. Acetaldehy gave, under similar conditions, low and variable result due possibly to the formation of iodoform.

The action of the hypoiodite upon solutions of suga was found to vary at first with the quantity of caust soda added, and the period of action of the hypoiodite.

A practically neutral hypoiodite solution was th made by adding 50 c.c. $N/10$ caustic soda to 50 c.c. $N/$ iodine. The sugar solutions were added to this solutio allowed to stand for about five minutes, acidified wi dilute acid and titrated with $N/10$ thiosulphate. many cases the reaction with the neutral hypoiodite w continued for from 30 mins. to 24 hours, the resu increasing gradually with increased period of acti The experiments were carried out with a 1% soluti of lactose. 25 c.c. of this was added to a mixture 50 c.c. of $N/10$ iodine and 50 c.c. of $N/10$ caustic so and in one case 25 c.c. of $N/10$ iodine and 25 c.c. of $N/$

caustic soda were employed. The following table shows the results :—

	1	2	3	4	5
Volume of $N/10$ iodine	25	50	50	50	50
Volume of $N/10$ NaOH	25	50	50	50	50
Time of action	30 m.	3 hrs.	7 hrs.	12 hrs.	24 hrs.
odine used	14·8	14·9	15·1	15·2	15·2

From the composition of a sugar can be calculated the amount of iodine that will be required to oxidise it into an acid, since neutral hypoiodite oxidises only the aldehyde group.

The following compounds have been dealt with: Dextrose, lævulose, sucrose, lactose, and maltose.

Dextrose contains one aldehyde group and should require one molecule of iodine or one molecule of hypoiodite to oxidise the aldehyde group. Working with pure dextrose (Kahlbaum) we found that the gram molecule of the sugar (180 g.) required 254 grams of iodine for oxidation.

In the whole of the experiments, the same strength of sugar solutions was used, namely—10 grams per litre; 25 c.c. of these solutions were added to 50 c.c. of $N/10$ iodine converted into neutral hypoiodite, allowed to stand for about five minutes, acidified, and titrated with $N/10$ thiosulphate.

In one experiment 25 c.c. of dextrose solution required 27·7 c.c. of iodine, representing 99·7% dextrose.

Laevulose and sucrose contain no aldehyde group and do not react with the neutral hypoiodite.

Sucrose on hydrolysis produces dextrose and lævulose, and one mol. should require one mol. of iodine as hypoiodite for oxidation. Two portions of 20 c.c. of pure sucrose (Kahlbaum) solution were heated with 10 c.c. of concentrated hydrochloric acid for ten minutes at 66°—68° C., cooled, neutralised, and treated with neutral hypoiodite. They required 11·8 c.c. and 11·85 c.c. $N/10$ iodine, equal, respectively, to 100·85% and 101·3% sucrose. Ordinary cane sugar gave 102·6%.

In all the experiments with cane sugar the figure after hydrolysis was higher than it should be; some samples of crude cane sugar, although without action before hydrolysis, gave as much as 104% after hydrolysis.

Lactose contains one aldehyde group and requires one molecule of iodine. The result in this case was 99·4%. Lactose on hydrolysis gives one molecule of dextrose and one molecule of galactose; after hydrolysis with 3% sulphuric acid a figure of 99·45% was obtained.

Maltose also contains one aldehyde group, and in this case the results obtained were 100·08 and 100·8%. After heating with 3% sulphuric acid for four hours in a bath of boiling water, maltose hydrolyses into two molecules of dextrose. A result of 99·9% was obtained.

The figures obtained directly by the hypoiodite method are given in the following table :—

	Dextrose.	Lævulose	Sucrose.	Lactose.	Maltose.
	%			%	%
Maximum	99·7	nil	nil	99·4	101·8
Minimum	96·4			99·1	99·9

Maximum	101·3	103·4	99·4	99·9
Minimum	100·8	102·6	99·1	99·1
Mean	101·1	103·0	99·3	99·5

We hope to be able to apply the method to the examination of starch and dextrin products used for sizing purposes. Simple mixtures containing two of the above sugars have been analysed fairly easily, but dextrin presented difficulties which we are attempting to overcome, an account of which will appear later.

Discussion.

Mr. F. W. Richardson said that he had done a large amount of work on this subject some time ago, but his discoveries as to the errors arising from the application of processes given in the standard books were of such a remarkable character that the Society before which the paper was read did not care to publish them. With a mixture of maltose, dextrose, dextrin, and invert sugar the ordinary methods were quite inadequate for a correct analysis. The least objectionable results arose from the application of polarimetry before and after complete inversion, and also after elimination of the invert reading at 187° F. with the conjunction of alcoholic precipitation for the dextrin and with copper methods carefully applied.

Dr. L. L. Lloyd said that the results obtained by the polarimeter when working with very dilute solutions of sugars were too variable to be of any use. The copper number along with the hypoiodite (iodine) number was found to be fairly constant and would probably be of much use.

Journal and Patent Literature.

ATENT SPECIFICATIONS may be obtained by post by remitting as follows :—
English.—8*d*. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s*. each, to the Secretary of the Society.
French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.
German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Rotary kiln; Development of the —— and its application to various chemical and metallurgical processes. R. K. Meade. J. Ind. Eng. Chem., 1914, **6**, 754—760.

An account of the advantages of the rotary kiln and its use in the manufacture of cement; for nodulising ores, cinder, etc.; burning lime; roasting bauxite, chemicals, etc.; manufacture of bichromates; burning pyrites; manufacture of sulphides; production of phosphatic fertilisers from phosphate rock, and of potassium compounds from lspar.—A. S.

External corrosion of cast-iron pipe. Pugh. *See* X.

Patents.

[*Mixing liquids.*] *Apparatus for the introduction of one liquid into another under pressure.* R. C. Parsons, London. Eng. Pats. 16,751, July 21, and 29,329. Dec. 19, 1913.

To maintain the proportion between the two liquids as constant as possible when the flow varies considerably, a pair of vertical injecting cylinders is used having pistons of slightly higher specific gravity than the liquid and both connected with an adjustable, constant-flow feeding device, and so arranged that the upward stroke of one piston synchronises with the downward stroke of the other. All mechanical friction is reduced as much as possible. (See also this J., 1914, 515).—W. H. C.

Mixer for liquids. B. Goldman. Fr. Pat. 468,959, Feb. 26, 1914. Under Int. Conv., April 22, 1913.

To promote the mixing, the blades of the agitator are only partially immersed in the liquid. They are adjustable vertically on the shaft so as to be adaptable to various depths of liquid.—W. H. C.

Drying machines or hydro-extractors; Centrifugal ——. H. C. Longsdon, Keighley. Eng. Pat. 22,261, Oct. 3, 1913.

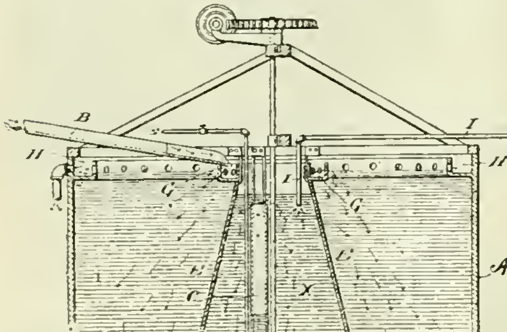
Locking devices flexibly connected together are provided for centrifugal machines with covers, so that the machine cannot be started until the cover is closed nor can the cover be opened until the machine is stopped. The drum can, however, be rotated by hand when the cover is open.—W. H. C.

Dryer; Mechanical —— with superposed parts. F. Fouché. Fr. Pat. 468,939, Feb. 25, 1914.

A number of drying chambers through which the material is carried on endless bands are arranged one above the other. The material passes down from band to band and the hot air or other drying medium is passed either upwards or downwards, or from the centre both up and down, or *vice-versa.* The tension and speed of each band can be adjusted independently and stirring devices and cleaning brushes may be provided. The hot air is obtained from a stove in which the hot gases pass through vertical passages grouped around a furnace and interposed between horizontal passages through which the air is passed.—W. H. C.

Thickening and agitating pulp; Process of and apparatus for ——. J. van N. Dorr, Denver, Colo., U.S.A. Eng. Pat. 22,411, Oct. 4, 1913.

The pulp flows from the shoot, B, and launder, G, into the tank, A. The clear liquid overflows through the launder, H, and the solid particles sink to the bottom where they are agitated by the rakes, J, and are elevated by the air-lift, C, and overflow into the agitating chamber, X, formed by the suspended conical partition, E. The heavier particles sink rapidly and are re-washed and re-elevated, and the lighter particles are discharged as a thickened mud through the pipe, I.—W. H. C.



Grinding mills. D. M. Clark, London. From Bradley Pulveriser Co., Boston, Mass., U.S.A. Eng. Pat. 6193, March 11, 1914.

To prevent leakage of lubricating oil from the universal coupling to the rotary shaft, a frusto-conical shield is provided, within the universal coupling, to retain the oil. —W. H. C

Furnaces for boiling or melting purposes. L. F. Tooth, London. Eng. Pat. 7636, March 26, 1914. Addition to Eng. Pat. 18,523, Aug. 12, 1912 (this J., 1913, 933).

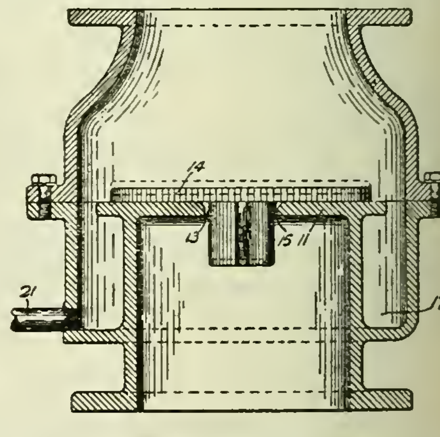
The furnace is built up of quadrant-shaped blocks and the annular flue is divided horizontally into an upper and a lower portion. The former communicates with the central heating chamber and the latter with the flue leading to the stack. The openings in the partition and those connecting respectively the heating chamber with the upper flue chamber and the lower flue chamber with the stack are arranged so as to cause the gases to traverse as long a path as possible.—W. H. C.

[*Kiln.*] *Art of treating vegetable and mineral matter by heat.* A. G. Waterhouse, Leonardo, and J. H. Van Mater, Atlantic Highlands, N.J. U.S. Pat. 1,105,729, Aug. 4, 1914; date of appl., Aug. 13, 1913.

A tunnel kiln for burning bricks or other products consist of an insulating conduit, held above its foundations by external, isolated supports, and having an under-passag throughout its length, formed between two hanging partitions, which extend downwards from the interior of the conduit into a water-seal. Two separate supports driven by external mechanism travel through the conduit in opposite directions and carry the material to be burnt which is heated on both sides whilst passing through the conduit.—O. R.

Gases; Extractor of liquids and solids from ——. J. T Wilkin, Assignor to The Connersville Blower Co. Connersville, Ind. U.S. Pat. 1,105,868, Aug. 4, 1914 date of appl., May 27, 1914.

The top, 11, of the central chamber of the apparatu (see fig.) has a circular aperture closed by a heavy, movabl plate, 14, from the under side of which a plug project into the opening. With sufficient pressure in the chamb the gas passes through the annular space, 13, 15, a thence, in a thin, radiating stream between the adjace horizontal surfaces of the place and its support, to t space above, the non-gaseous constituents accumulati in the annular channel, 17, and being discharged throu the pipe, 21.—W. E. F. P.

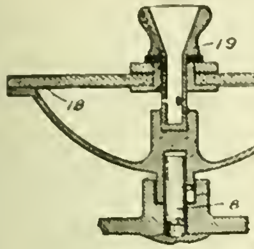


Evaporator. E. Zaremba and O. Mantius, Buffalo, N. Assignors to Zaremba Co. U.S. Pat. 1,106,532, Aug. 1914; date of appl., Aug. 22, 1912.

A vessel for the evaporation of acid or other corros liquids *in vacuo* consists of a steel or cast iron cylindri shell lined with refractory bricks or slabs which built in and domed or arched so that the lining can it withstand pressure from without. The heating medi is passed through a group of horizontal pipes of ac resisting material which extend from acid-resist tube-plates and protected steam-chests fixed on oppo sides of the lower part of the vessel.—W. H. C.

Extractor ; Centrifugal —— O. E Beach, Assignor to F. W. Braun, Los Angeles, Cal. U.S. Pat. 1,105,954, Aug. 4, 1914 ; date of appl., Aug 21, 1912.

THE material is fed into the cup-shaped vessel, 12, otating about the spindle, 8, through the hollow screw, 19, which serves to clamp a transparent cover, 17, on o the vessel. A layer of filtering material, 18, is interosed between the upper edgo of tho vessel and the over.—W. H. C.



lastic materials [Soap, clay, etc.] ; Treatment of ——. A. L. Mowry and F. A. Secord. Fr. Pat. 468,002, Feb. 3, 1914.

HE material is forced through a conduit by a hollow rew conveyor, and issues at the further end in a ctangular form. It is heated or cooled during its assage through the apparatus by circulating a heating r cooling medium through the screw conveyor.—W. H. C.

ilter-press. R. Christiansen. Fr. Pat. 468,565, Feb. 17, 1914.

HEATING agent is passed through a pipe disposed in a iral groove formed in the outer surface of the casing hich surrounds the press-plates.—W. H. C.

anks and reservoirs ; Process for lining ——. Comp. du Ciment-Verre. Fr. Pat. 469,064, May 10, 1913.

HE tanks are lined with enamelled metallic plates ined together by a solder which will resist the action f the liquid they are destined to contain.—W. H. C.

urnaces ; Regenerative gas ——. F. K. Siemens, London. Eng. Pat. 28,049, Dec. 5, 1913. Addition to Eng. Pat. 10,824, May 7, 1912.

EE Addition of Jan. 1, 1914, to Fr. Pat. 461,938 of 1913 ; is J., 1914, 850.—T. F. B.

rying apparatus. C. Grau, Niedernzwil, Switzerland. U.S. Pat. 1,107,294, Aug. 18, 1914 ; date of appl., Sept. 23, 1912.

EE Fr. Pat. 447,238 of 1912 ; this J., 1913, 275.—T. F. B.

ases ; Apparatus for purifying [waste] ——. A. Müller, Leipzig-Schleussig, and C. Bomhard, Berlin. U.S. Pat. 1,107,986, Aug. 18, 1914 ; date of appl., Dec. 2, 1909.

EE Eng. Pat. 17,380 of 1909 ; this J., 1910, 932.—T.F.B.

parating solid matter, more particularly cellular matter, from liquids ; Apparatus for ——. B. Hofer, Munich, Germany. U.S. Pat. 1,108,095, Aug. 18, 1914. Date of appl., April 22, 1914.

EE Eng Pat. 6793 of 1914 ; this J., 1914, 939.—T. F. B.

paration of materials ; Process for effecting the ——. R. Jaffé, Frankfort, Germany. U.S. Pat. 1,109,529, Sept. 1, 1914. Date of appl., March 16, 1912.

EE Ger. Pat. 255,531 of 1911 ; this J., 1913, 351.—T.F.B.

Vacuum ; Process for producing and maintaining a high ——. Sudfeldt und Co. Fr. Pat. 468,434, Feb. 13, 1914.

SEE U.S. Pat. 1,100,694 of 1914 ; this J., 1914, 781.—T.F.B.

IIA.—FUEL ; GAS ; MINERAL OILS AND WAXES.

Vertical retorts ; Wilson's "continuous-intermittent" ——. J. Dickson. J. Gas Lighting, 1914, **127**, 615—621.

THE "continuous-intermittent" process consists in making gas continuously in vertical retorts which are partially discharged and filled up with fresh coal at short intervals. The process has been in use for a year at Johnstone, with an installation comprising three settings of 4, and one of 6 retorts, each capable of carbonising 3 tons of coal per 24 hours, and each setting having a separate gas-producer. The retorts were designed to suit the secondary coking coals of Scotland and are 23 ft. high, 3 ft. 4 in. by 10 in. at the top, tapering a distance of 11 ft. 6 in. to 4 ft. by 1 ft. 6 in. 7 cwt. of coke is withdrawn every 4 hrs. leaving 6 to 7 ft. at the top of the retort to be recharged. Compared with horizontal retorts used previously, there was a saving in labour cost during the year equivalent to 1·47d. per 1000 cb. ft. of gas, on an output of 9¾ million cub. ft. The yield increased from 9820 to 10,113 cb. ft. of gas, from 12·90 to 14·63 galls. of tar, and from 26·50 to 28·99 lb. of ammonium sulphate per ton, while coke fell from 9·90 to 8·78 cwt. per ton, these results being obtained with a cheaper coal than that previously used. During the last two months of the period reported on, the yield was 10,808 cb. ft. of gas, 15·69 galls. of tar and 29·48 lb. of sulphate per ton, with a consumption of 16·42 lb. of coke per 100 lb. of coal carbonised. The gas has calorific value 647 B. Th. U. gross and 583 B. Th. U. net, and the illuminating power is 17 c.p. Naphthalene stoppages have fallen from 195 to 23 during the periods May—July 1913 and 1914. The yield of gas per ton was greater by 400—500 cb. ft. when the charging period was increased to 4 hrs. 48 min., but the calorific value fell to 593 B. Th. U. gross and 534 B. Th. U. net, the candle-power to 15·6 and the fuel consumption increased to 18 lb. of coke per 100 lb. of coal. The composition of the gas was :—

Charging period	4 hrs. 48 min.	4 hrs.
	%	%
Carbon dioxide	3·05	3·10
Illuminants	3·30	5·00
Oxygen	0·45	0·50
Carbon monoxide	9·90	7·50
Methane	28·35	33·90
Hydrogen	49·80	43·25
Nitrogen	5·15	6·75

The retorts run 6 to 7 weeks without scurfing. At the first sign of sticking up, the retort is worked till empty, the carbon burnt off by admitting air at the bottom, any remaining carbon is removed with a light bar, the retort is filled with coke to within 7 ft. of the top, and charged with coal some time after. The whole process occupies 54—56 hrs.—A. T. L.

Transformer oils. W. Brauen. Chem. Rev. Fett. Ind., 1914, **21**, 138—139, 170—171.

ONLY mineral and rosin oils are now used in transformers ; most of those sold are neutral, and have high flash and ignition points, good insulation capacity and low viscosity. Since mineral and rosin oils are hygroscopic, electrical conductivity determinations should be applied to the oil previously dried or heated to 100° C. In use the mineral oils are oxidised, with formation of acids which attack the metals, especially the lead, of the transformer, to form compounds sparingly soluble in oil, leading to the production of solid yellow to black deposits in the transformers. The insolubility of the acids in petroleum spirit indicates the presence of hydroxy-acids. Their saponification value is about 187. The formation of acids increases with the temperature and time, and the presence of copper promotes the oxidation. Oils containing sulphur undergo pronounced decomposition in transformers. The solid deposits contain up to 30% of ash, and are partially soluble in hot mineral oil and soluble in benzene, from which they can be reprecipitated by petroleum spirit. All types of crude or slightly refined mineral oils yield these solid deposits, whereas highly-refined colourless or light yellow oils, which have been treated with concentrated sulphuric acid, are equally oxidised, but instead of yielding a deposit, form acid vapours, oil-soluble acids, and water. These products strongly attack the metals and insulating material. The acids have a pronounced oxidising action and liberate iodine from potassium iodide. As a practical test of the stability of an oil a current of air, oxygen or ozone is passed through the sample heated to the desired temperature in a glass vessel. The deposits of liquid acid products thus obtained are identical with those formed in a transformer. Mineral oils rich in hydrocarbons with open carbon chains are particularly liable to decomposition, whilst those rich in cyclic hydrocarbons are more stable. In practice oils containing aromatic hydrocarbons have proved the most suitable. Rosin oil (flash point 158° to 160° C.; ignition point, 170° to 180° C.) is preferable to mineral oils. The volatility is only slightly higher, whilst the insulation capacity is better than in the case of mineral oils. The oxidation products are soluble in the rosin oil and do not attack the metal or insulating material, whilst water is not formed in the decomposition. Owing to slight polymerisation rosin oil thickens more than mineral oil of equal viscosity, but since its viscosity decreases much more rapidly with rising temperature, it always remains sufficiently fluid to circulate in the transformer. To obviate the action of atmospheric oxygen upon mineral oils, transformers are made in which contact of the air with the hot oil is prevented, but these are only partially successful, since the air dissolved by the oil is able to produce the deposits and acid-formation, with the liberation of water. Rosin oil that has become viscous after many years' use can be made sufficiently fluid again by the addition of fresh oil. Mixtures of mineral and rosin oils should not be used, since they undergo decomposition in the same manner as mineral oils. (See also this J., 1910, 406; 1911, 696, 697; 1912, 62, 114.)—C. A. M.

Coke production in the United States in 1913. E. W. Parker. U.S. Geol. Survey. Mineral Resources, 1913, 455—520. [T.R.]

The production of coke in the United States in 1913 amounted to 46,299,530 short tons, valued at $128,922,273 compared with 43,989,599 tons in 1912, value $111,805,113. The amount of coal consumed in coke manufacture in 1913 was 69,239,190 tons. Of the 1913 production, 33,584,830 tons, value $80,284,421, was beehive or "oven" coke and 12,714,700 tons, value $48,637,852 was by-product or "retort" coke. Nearly 70% of the increase in the production in 1913 was due to retort coke. The total number of ovens and retorts in operation in the United States in 1913 increased from 102,230 to 102,650, but the number of beehive ovens decreased by 57. Th average production of oach retort oven was about 230 tons, and of each beehive oven 505 tons. A marke tendency to consolidation into larger units is shown, th number of coke establishments having decreased fror 578 in 1910 to 551 in 1913. The total value of the coke gas, tar, ammonia, and other products produced at by product recovery ovens during the last three years shown in the following table:—

Product.	1911.		1912.		1913.	
	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
Gas (thousand cb. ft.)	33,274,801	$3,781,218	54,491,248	$4,650,517	64,553,941	$5,694,69
Tar (galls.)	69,410,599	1,638,314	94,306,583	2,310,900	115,145,025	2,830,15
Ammonia, sulphate or reduced to equivalent in sulphate (lb.)	72,920,056	1,943,761	95,275,545	3,649,144	173,342,349	5,324,44
Ammonia liquor (galls.)	4,660,596	548,824	5,502,403	735,120	4,102,448	537,41
Anhydrous ammonia (lb.)	23,180,118	1 847,929	*26,672,474	*2,387,562	*28,663,936	*2,135,65
Other by-products	—	273,915	—	610,552	—	403,57
Total value of by-products	—	10,033,961	—	14,343,795	—	16,925,94
Coke (short tons)	7,847,845	27,297,897	11,115,164	42,632,930	12,714,700	48,637,85
Grand total	—	37,331,858	—	56,976,725	—	65,563,79

* Mainly ammoniacal liquor sold on pound basis of NH_3.

The gas included in the table is the "surplus" n consumed in the coking process, which is either used manufacturing establishments operated in connecti with the coke-oven plant or sold. At the close of 19 there were 5211 retort ovens in operation, and 793 we building. The completed ovens consisted of 2100 Unite Otto ovens (including the Otto-Hoffmann and Schniewi types), 1443 Semet-Solvay, 281 Rothberg, 1,215 Koppe 150 Didier, and 22 Klönne ovens. At the close of 19 there were 5688 ovens working, and 504 ovens buildi The new construction added in 1913 consisted of Semet-Solvay ovens, 66 Koppers, and 150 Didier ove There were 200 United-Otto ovens abandoned. T ovens building included 334 Koppers ovens, 152 Sem Solvay ovens, and 18 Wilputte ovens.

California petroleums; The specific heat of——. H. Wales. J. Ind. Eng. Chem., 1914, **6**, 727—728.

The results given are:—

	Composition of oil.					Speci heat at 20°
	Water.	0°—150° C.	150°—300° C.	Above 300° C.	Asphaltum.

Hydrogenation of oils, and synthetic fatty acids [f petroleum]. Colletas. *See* XII.

Patents.

Lignite; Treatment [drying] of——. T. Rigby, Dumfr Scotland, and N. Testrup, London. Eng. Pat. 18, Aug. 20, 1913.

In a drying plant such as that described in Eng. P 24,748 of 1911 and 969 of 1912 (this J., 1913, 77, 353) temperature of the issuing gases is maintained between 75° and 150° C. by varying the feed of lignite in relation to the volume of hot gases. The drying duct and its auxiliaries are made strong enough to sustain an explosion, the force of which is dissipated through an outlet to the atmosphere.—O. E. M.

Peat or bog material; Treatment of —— for industrial purposes. A. Dickson, S. Geoghegan, and A. Smythe, Dublin. Eng. Pat. 18,932, Aug. 20, 1913.

Peat in a liquid state is fermented at 90° F. (32·2° C.) by the addition of yeast; the solid matter separates, and is further dried mechanically.—O. E. M.

Coke; Machine for quenching and discharging ——. Maschinenbau-Anstalt Humboldt. Fr. Pat. 467,891, Jan. 30, 1914.

A portable casing, mounted on a trolley, receives the coke from any chamber of the oven and carries it to a central discharging pit. The casing is of ∩-section, and is suspended from its upper end over a fixed base-plate. The coke is discharged from the ovens into this casing through a tubular member fitted with water sprayers. The trolley is brought to the central pit and by swinging the casing aside from its base-plate the coke is discharged down a fixed inclined plate, where a further quantity of water is supplied for quenching. The lower part of this plate is perforated for the escape of water and coke dust. At the bottom of the inclined plate, and forming a continuation thereof, is a series of discharging hoppers which can be adjusted vertically to regulate the passage of the coke to a conveyor and elevator.—A. T. L.

Retorts for continuous distillation of coal; Vertical ——. Comp. Gen. de Construction de Fours. Fr. Pat. 468,808, May 3, 1913.

Air-heating flues are arranged around the lower parts of the retorts, and dampers are provided so that the hot air can be directed at will either to the gas generator or to the regenerators and thence to the combustion chambers.—A. T. L.

Acetylene gas; Storing of dissolved ——. G. L. Wilkinson, Middle Town, Conn., U.S.A. Eng. Pat. 18,745, Aug. 18, 1913.

Silk waste is used for absorbing the solvent used to dissolve the acetylene.—W. H. C.

Ammonia from producer gas; Apparatus for absorbing ——. E. S. Mond, London. Eng. Pat. 17,779, Aug. 2, 1913.

The gas is passed through a long vessel, provided with two or more lutes for the removal of tar, and containing acid, which is sprayed up into the gas space by means of revolving dashers. The vessel consists of a steel framework, comprising vertical sections connected together by horizontal members, which support a lead shell resting on a lead floor, the vertical sides and the floor being burnt together and on to long lead straps, which are lapped over the angles of the frame. The roof is supported by longitudinal lead straps lapped over the longitudinal angles of the framework, and by curved metal straps covered with lead and bolted to the uppermost horizontal angle at the side of the framework. The dashers are supported by bearings built on a foundation, which is separate from the framework, the dasher shaft passing through a gland fixed in a vertical cast-iron plate, which may form part of the bearing and be covered with lead on the inside.—O. R.

Hydrocyanic acid in crude coal gas; Recovering as an ammonium salt the nitrogen of the ——. South Metropolitan Gas Co. and E. V. Evans, London. Eng. Pat. 29,047, Dec. 16, 1913.

The hydrocyanic acid is converted in the known manner into ammonium sulphocyanide (thiocyanate), and the latter is hydrolysed by an acid, preferably sulphuric acid, at about 50° C., and under conditions of concentration and proportions by mass suitable for obtaining a maximum yield of ammonia in the form of an ammonium salt. The quantity of sulphuric acid used may be equivalent to the ammonium sulphate to be produced by hydrolysis of the thiocyanate and the ammonia in the gas from which the thiocyanate has been made, and the acid liquor left after the hydrolysis is then supplied to the saturator in which the ammonia in the gas is converted into sulphate. The conditions of concentration, etc., leading to the maximum yield of ammonia in the hydrolysis are such that no appreciable precipitate is produced in the liquor and no appreciable quantity of volatile nitrogenous products escapes. They must be determined experimentally in particular cases, but with a 25—30% solution of ammonium thiocyanate, 1 vol. of this is heated at 80°—110° C. with 1·5 vol. of 70—80% sulphuric acid: 96—99% of the theoretical quantity of ammonia is recovered. The reaction is: $NH_4SCN + H_2O = COS + 2NH_3$.—A. S.

Coal gas and similar gases; Purification of —— with recovery of by-products. K. Burkheiser. Fr. Pat. 469,122, Feb. 28, 1914.

Hydrogen sulphide is absorbed by an alkaline emulsion of hydrated iron oxide and free sulphur. The mixture of iron sulphides and free sulphur formed, is treated with an alkali sulphide to extract the free sulphur, and the iron sulphides are oxidised so as to regenerate an emulsion of hydrated oxide and free sulphur. The alkali necessary for the absorption may be provided by the ammonia present in the crude gas, the temperature of the washing liquor being regulated so as to leave the requisite quantity of ammonia in the gas. The cyanogen in the crude gas is also absorbed, soluble thiocyanates being formed. The solution from the extraction with alkali sulphide is heated to 90—100° C. to precipitate free sulphur, the thiocyanates remaining in solution. The hydrogen sulphide and ammonia set free by heating the solution are returned to the purifier. The free sulphur is burned and the sulphur dioxide used for absorbing ammonia from the coal gas.—A. T. L.

Combustion of combustible mixtures. C. D. McCourt, Streatham Common, and Bonecourt Surface Combustion, Ltd., London. Eng. Pat. 18,542 of 1913; date of appl., Jan. 15, 1914.

The flues are packed with bricks or shaped pieces of refractory material set at an angle with one another so as to form a tortuous passage which decreases in cross-section in proportion to the reduction in temperature of the burning or burnt products of combustion passing through it.—W. H. C.

Hydrocarbons [of coal distillation gases]; Conversion of aliphatic —— into alcohols. J. de Lattre. Fr. Pat. 468,244, Feb. 9, 1914.

Coal distillation gases, especially those produced during the early stages in coke ovens, are freed from hydrogen sulphide, tar, and aromatic hydrocarbons, and then passed through concentrated sulphuric acid, preferably in presence of vanadium or uranium oxide; the ethyl hydrogen sulphate produced is converted into ethyl alcohol by means of water. The residual gas, containing methane and its homologues, is mixed with an equal volume of chlorine and subjected to the action of ultra-violet rays; the chlorohydrocarbons thus formed are converted into the corresponding alcohols by treatment with an alkali or alkaline-earth.—T. F. B.

Gasolene or naphtha; Machine for refining used ——. G. E. Olsen, Laconia, N.H. U.S. Pat. 1,106,887, Aug. 11, 1914; date of appl., April 14, 1913.

The naphtha is displaced upwards by water into a small dome at the top of a tank fitted with agitating gear, and passes off through a pipe having a transparent portion for inspection of the liquid.—O. E. M.

[Light petroleum] spirit, petroleums, and benzols; Process and apparatus for the continuous rectification of ——. E. Barbet et Fils et Cie. Fr. Pat. 468,068, April 12, 1913.

The process comprises two operations in each of which a triple or other multiple effect is used in conjunction with a rectifying column; with triple effects, crude petroleum can be separated into 11 distinct fractions. In the case of petroleum, the lighter spirit is separated in the first operation and the illuminating and heavy oils in the second. The process differs from that of ordinary triple effect evaporation in that the same (atmospheric) pressure is maintained in each section of the first series, and the same, lowest possible pressure is each section of the second series. Further, in each series, the liquid and vapour pass from section to section in opposite directions, *i.e.*, the first section for the liquid is the last section for the vapour and inversely.—L. E.

Boiler or still for liquid hydrocarbons (petroleum); Electrically-heated ——. T. Delort. Fr. Pat. 469,054, Feb. 8, 1913.

Two stills are described. In the first the oil flows downwards in a zig-zag path between a series of inclined plates, heated electrically by internal resistances. The vapours pass from the still-head downwards through a condenser, and the whole is immersed in oil in an outer vessel also provided with still-head and condenser. The second form of still comprises a vessel, with walls encased in non-heat-conducting material, containing a number of horizontal plates forming the electrical resistances.—A. T. L.

Dust [in mines, etc.]; Composition for agglutinating ——. H. Belger, Cullercoates. U.S. Pat. 1,107,880, Aug. 18, 1914. Date of appl., April 8, 1913.

See Eng. Pat. 6343 of 1913; this J., 1913, 690.—T. F. B.

Coal gas; Apparatus for the manufacture of ——. R. C. Congdon, Atlanta, Ga., U.S.A. Eng. Pat. 9587, April 17, 1914. Under Int. Conv., April 29, 1913.

See U.S. Pat. 1,090,813 of 1914; this J., 1914, 471.—T.F.B.

Gas-producer; Suction ——. M. F. Derrick, Montreal, Canada. U.S. Pat. 1,107,917, Aug. 18, 1914. Date of appl., June 12, 1913.

See Eng. Pat. 14,153 of 1912; this J., 1913, 860.—T.F.B.

Ammonia and sulphur compounds from gas; Process of extracting ——. J. W. Cobb, Leeds. U.S. Pat. 1,108,705, Aug. 25, 1914. Date of appl., May 31, 1913.

See Eng. Pat. 13,141 of 1912; this J., 1913, 971.—T.F.B.

Motor-spirit. R. de Fazi, Rome. U.S. Pat. 1,108,351, Aug. 25, 1914. Date of appl., Oct. 31, 1912.

See Eng. Pat. 25,177 of 1911; this J., 1913, 187.—T.F.B.

Process of and means of obtaining phenols from tar oils, applicable also for other purposes [e.g. refining petroleum]. Eng. Pat. 20,077. *See* III.

Complete extraction of industrial chemical products contained in crude ammoniacal liquor. Fr. Pat. 468,535. *See* VII.

Apparatus for determining the percentage of carbon dioxide in flue gases. Eng. Pat. 21,542. *See* XXIII.

Patent Case.

Peat and the like; Treatment of (extracting water from) ——. J. E. Jameson and O. H. Valpy, London, and E. A. Buckle, Manchester. Eng. Pat. 10,370 of 1912 (this J., 1913, 590). Repts. of Patent Cases Vol. XXXI. Ill. Off. J. Patents. Sept. 9th, 1914, 361. By permission.

This was a petition in Chancery for revocation of Jameson's patent, which claimed a process for the extraction of water from peat, by passing an electric current through peat pulp, heated to a temperature of at least 100° C., under a pressure such that no steam is produced. It was proved that the water in peat is partly free and partly combined in the form of "hydrocellulose," and that the combined water could not be got rid of by pressure. Prior to the patent it had been suggested that the water could be removed by the use of a comparatively high temperature and pressure. The patentees said that the result could be attained by the use of an electric current (the voltage of which might vary within wide limits) at a lower temperature. The petitioner contended that the only result obtained by the use of the current was due to its heating effect.

The Court held that the specification described a process in which the electric current was used to effect the decomposition of the "hydrocellulose" without recourse for that purpose to heat, while the earlier process depended on the effect of heat alone. The process had been in operation on a practical scale for some time, with the result that a pressed cake had been produced suitable either for fuel or for consumption in a gas producer for the production of ammonium sulphate. The process was useful and the directions given were sufficient. A certificate of validity was given and the petition was dismissed with costs.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Ligneous materials; Treatment [dry distillation] of peat, sawdust, nutshells, and other ——. R. F. Strong, London. Eng. Pats. 15,980 of 1914, and 18,984 of 1913; dates of appl., Aug. 21, 1913.

For the production of alcohol, acetic acid, acetone, motor spirit, etc., raw peat is masticated in a retort connected with a condenser. The partly carbonised peat falls by stages to the bottom of a second retort fitted with shelves and slowly rotating rakes, and connected with a condenser. The condensed tarry liquid, with or without separation of acetic acid and other products, is "cracked" in a coil heated by the red hot carbonised peat in a third chamber: the liquid products are condensed, and the gases are scrubbed and used for firing the retorts. The apparatus is suitably modified for dealing with nutshells, sawdust, etc.—O. E. M.

Wood alcohol; Refining ——. L. F. Hawley, Assignor to A. D. Little, Inc., Boston, Mass. U.S. Pat. 1,106,707, Aug. 11, 1914; date of appl., April 13, 1914.

By repeated treatment with an aqueous solution of alkali an acetone layer substantially free from methyl alcohol, and a methyl alcohol layer containing small quantities of acetone, are obtained. The acetone layer is purified by dissolving out the alcohol with aqueous alkali.—O. E. M.

Furnaces for heating gases. C. M. T. Olsson, Nygard, Sweden. Eng. Pat. 11,774, May 20, 1913.

Heat is transferred from the hot to the cold gases, ascending in separate superimposed chambers fitted with baffles of chequer-brickwork, by a falling stream of sand, which passes successively through the chambers.—O. E. M.

Incandescence body for electric lamps. W. G. Hughes, Pittsburgh, Pa. U.S. Pat. 1,106,384, Aug. 11, 1914; date of appl., Dec. 16, 1912.

A filament of pure, drawn, annealed, metallic uranium is produced from a mixture of uranium chloride, metallic sodium and potassium chloride.—B. N.

Glow-lamp; Electric ——. W. Nernst, Göttingen, Germany, Assignor to Nernst Lamp Co. U.S. Pats. (A) 1,106,960 and (B) 1,106,961, Aug. 11, 1914; dates of appl., Sept. 10, 1908 and April 24, 1913.

(A) The glower for lamps of the Nernst type, non-conductive at atmospheric temperatures but conductive at high temperatures, is composed of an intimate mixture of yttria and a relatively small proportion of tungstic acid, formed into the desired shape and thoroughly baked. (B) The homogeneous conductor is composed of intimately mixed oxides of calcium and tungsten.—B. N.

Filaments and mantles used in incandescent gas-lighting; Process for impregnating the ——. G. Bagrachow, Paris. U.S. Pat. 1,108,116, Aug. 25, 1914. Date of appl., July 13, 1911.

See Eng. Pat. 18,084 of 1910; this J., 1911, 530.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Autoxidations [of xylene and benzaldehyde]. IV. Communication on chemical action of light. H. Suida. Ber., 1914, **47**, 467—472.

It was shown previously (Monats. Chem., 1912, **33**, 1268) that xylene mixed with an aromatic nitro-hydrocarbon contained more active oxygen after exposure to light and oxygen than pure xylene so treated. In further experiments involving exposure to sunlight for six months, and the working up of the products of the oxidation, it was found that the presence of the nitro-compound reduced the total yield of oxidation product, but that considerable quantities of toluic aldehyde were present. Thus, in presence of the nitro-hydrocarbon the less stable products of oxidation, aldehydes and peroxides, remained, whilst the pure chemical reaction—the decomposition of these primary products to the next higher and more stable stage of oxidation—was delayed. It was possible by cooling in carbon dioxide and ether to bring almost to a standstill the decomposition of the benzoyl-hydroperoxide formed from benzaldehyde by the action of ultra-violet light, but the product of the primary autoxidation process could not be isolated, as it decomposed into benzoic acid within a few minutes of removing from the cooling mixture.

—G. F. M.

Phenanthraquinone; Action of the benzene hydrocarbons on —— *in sunlight.* A. Benrath and A. v. Meyer. J. prakt. Chem., 1914, **89**, 258—270.

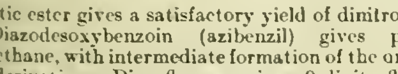
Phenanthraquinone when exposed to light with *o*- or *p*-xylene, ψ-cumene, or quinaldine, forms addition products, probably ethers of phenanthrenequinol, *e.g.*,

$$\begin{array}{ll}C_6H_4.C.O.CH_2.C_6H_4.CH_3 \\ | \qquad \| \\ C_6H_4.C.OH\end{array} \quad \text{or} \quad \begin{array}{ll}C_6H_4.CH.O.CH_2.C_6H_4.CH_3 \\ | \qquad \quad | \\ C_6H_4.C:O\end{array}$$

from o-xylene. *m*-Xylene, mesitylene, *p*-cymene, toluene and ethylbenzene cause reduction of the phenanthraquinone, without formation of any addition product.—J. B.

Diazo-compounds and tetrazenes, The action of nitrogen peroxide on aliphatic ——. H. Wieland and C. Reisenegger. Annalen, 1913, **401**, 244—251.

The action of nitrogen peroxide on aliphatic diazo-compounds is analogous to that of bromine—nitrogen is split off and a dinitro-compound formed—



$$R{\cdot}CH\left<\begin{matrix}N\\ \|\\ N\end{matrix}\right. + 2NO_2 = R{\cdot}CH\left<\begin{matrix}NO_2\\ \\ NO_2\end{matrix}\right. + N_2$$

Diazoacetic ester gives a satisfactory yield of dinitro-acetic ester. Diazodesoxybenzoin (azibenzil) gives phenyldinitromethane, with intermediate formation of the unstable benzoyl-derivative. Diazofluorene gives 9-dinitrofluorene

$$\left.\begin{matrix}C_6H_4\\ \dot{C}_6H_4\end{matrix}\right>C(NO_2)_2$$

The tetra-aryltetrazenes behave differently, for, whereas with bromine they give bromo-amines, instead of giving the corresponding diarylnitramines with nitrogen peroxide a smooth nitration of two symmetrically disposed benzene rings takes place and no nitrogen is split off. A dark green addition product is first formed, to which the constitution: $C_6H_5:(NO_2):N(NO_2)(C_6H_5).N_2.N(NO_2)(C_6H_5):C_6H_5:(NO_2)$, is ascribed. This loses 2 mols. HNO_2 to give dinitrotetraphenyltetrazene,

$$(NO_2)C_6H_4.N(C_6H_5).N_2.N(C_6H_5).C_6H_4(NO_2).$$

The reaction is carried out by adding a benzene solution of nitrogen peroxide to the diazo-compound. Nitric acid acts catalytically to decompose the diazo-compound.

—J. B.

β-Anthraquinone-aldehyde. A. Eckert. Monatsh. Chem., 1914, **35**, 289.

β-Anthraquinone-aldehyde was converted into β-anthraquinoylacrylic acid by the usual method with a view to carrying it through the steps of Baeyer's Indigo synthesis. The action of nitric acid, however, on the acid was to give not nitro-anthraquinoylacrylic acid, but 1-nitroanthraquinone-aldehyde, the same product as that obtained by direct nitration of β-anthraquinone-aldehyde.

—J. B.

Patents.

Tar and like substances; Apparatus for melting or boiling ——. R. P. Brousson, London. Eng. Pat. 2058, Jan. 26, 1914.

A cauldron or tank for boiling tar, flux oil from petroleum, etc., is provided with a perforated tray supported by means of brackets at some distance from the walls of the vessel. The material to be heated is poured between the tray and the walls of the vessel. This construction of apparatus is especially suitable for use in treating materials such as asphaltic bitumen, and ensures rapid dispersion of froth.—T. F. B.

Phenols from tar oils; Process of and means for obtaining —— *applicable also for other purposes.* A. Pepper, Tunstall, Staffs. Eng. Pat. 20,077, Sept. 5, 1913.

Tar oils and caustic soda solution are heated in separate tanks and then brought together into a vessel in which they fall on a series of circular baffle-plates, below each of which is a partition with a central opening, so that the mixture has to take a circuitous path before it reaches the separating tank. This tank is provided with one or more vertical curtain-plates, and from it the oil and aqueous solution are run off to stock tanks, or the oil is again treated with caustic soda in a similar manner. This process may also be used for washing and refining petroleum, benzol, and other oils.—T. F. B.

Aromatic hydroxy derivatives; Process for producing ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 469,040, Feb. 10, 1914. Under Int. Conv., May 26, 1913.

The formation of oxidation products, which always occurs when aromatic sulphonic acids are fused with alkali hydroxides, can be avoided if the two substances are heated together in aqueous solutions at high temperatures (*e.g.*, 300° C.). *Example.*—A mixture of 46 parts of the sodium salt of naphthalene-β-sulphonic acid and 50 parts of caustic soda lye of 40° B. (sp. gr. 1·385) is heated in a closed vessel for 10 to 20 hours at 300°—330° C. The cooled mass is acidified and the β-naphthol is filtered, washed, and dried. A good yield of the phenol, only very slightly coloured, is obtained.—T. F. B.

Process and apparatus for the continuous rectification of essences [light petroleum], petroleums, and benzols. Fr. Pat. 468,068. *See* IIa.

IV.—COLOURING MATTERS AND DYES.

Azoxy-compounds ; Certain —— and the action of dinitrophenylpyridine chloride on sulphonated substances. F. Reitzenstein and R. Fitzgerald. J. prakt. Chem., 1914, **89**, 271—289.

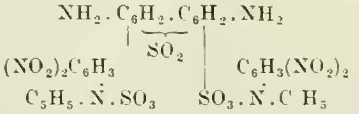
The product obtained by oxidising diaminodiphenylmethane in alkaline solution (this J., 1910, 1098) is an azoxy-compound, viz., *p*-*p*′-diamino-*p*-azoxydiphenylmethane,

$$\mathrm{NH_2.C_6H_4.CH_2.C_6H_4.}\underset{\mathrm{O}}{\underbrace{\mathrm{N{-}N}}}\mathrm{.C_6H_4.CH_2.C_6H_4.NH_2}.$$

and a similar compound,

$$\mathrm{NH_2.}\underbrace{\mathrm{C_6H_2(SO_3H).C_6H_2(SO_3H)}}_{\mathrm{SO_2}}\mathrm{.}\underset{\mathrm{O}}{\underbrace{\mathrm{N{-}N}}}\mathrm{.}\underbrace{\mathrm{C_6H_2(SO_3H).C_6H_2(SO_3H)}}_{\mathrm{SO_2}}\mathrm{.NH_2}$$

results from the oxidation of benzidinesulphonedisulphonic acid. In the latter case the oxidation product is always the same, whatever be the oxidising agent used, in contrast with the behaviour of diaminostilbenedisulphonic acid which gives different products with different reagents (*loc. cit.*). The compound from diaminodiphenylmethane dyes wool red and gives a red azo-compound when diazotised and combined with β-naphthol. The compound from benzidinesulphonedisulphonic acid is a yellow substance and dyes wool an intense red. It is peculiar in that it does not give the ordinary reaction of an amino-compound with dinitrophenylpyridinium chloride according to Zincke's method, *i.e.*, $2R.NH_2+C_5H_5N(Cl)C_6H_3(NO_2)_2 \rightarrow R.NH(HCl)—.C_5H_5NR + C_6H_3(NO_2)_2.NH_2$, but simply gives a sulphonate of the reagent, no dinitraniline being produced. The parent substance, benzidine-sulphone-disulphonic acid, behaves similarly, giving :—

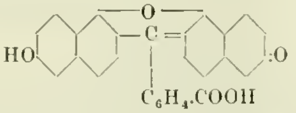


$$\begin{array}{ccc} & \mathrm{NH_2.\,C_6H_2.\,C_6H_2.\,NH_2} & \\ & \underbrace{\qquad}_{\mathrm{SO_2}} & \\ \mathrm{(NO_2)_2C_6H_3} & & \mathrm{C_6H_3(NO_2)_2} \\ \mathrm{C_5H_5\,.\,\dot{N}\,.\,SO_3} & & \mathrm{SO_3\,.\,\dot{N}\,.\,C\;H_5} \end{array}$$

Diaminostilbenedisulphonic acid and benzidine-*m*-disulphonic acid, also the azoxy-compounds derived from them, all give this peculiar reaction. All these sulphonic acid salts of dinitrophenylpyridinium are coloured and dye wool. The amino-groups condense in the usual way with dimethylaminobenzaldehyde. 2-Naphthylamine-6-sulphonic acid gives an azine with alkaline oxidising agents.—J. B.

6.6′-*Dihydroxynaphthofluoran. Action of phthalic anhydride on* 1.6-*dihydroxynaphthalene.* O. Fischer and E. König. Ber., 1914, **47**, 1076—1084.

By melting 1.6-dihydroxynaphthalene with phthalic anhydride a red substance is formed which gives a blue-green alkali-compound and a red oxonium salt with hydrochloric acid. With diazonium salts it forms bis-azo-compounds which are insoluble in alkali and are thus analogous to the azo-compounds of β-naphthol, whence it follows that the substance is probably 6.6′-dihydroxynaphthofluorane :—



The lactone form of the compound is unstable and exists only in solution or in combination with ether or acetone of crystallisation.—J. B.

Anthraquinone ; Benzyl derivatives of ——. M. Tschilikin. Ber., 1914, **47**, 1055—1058.

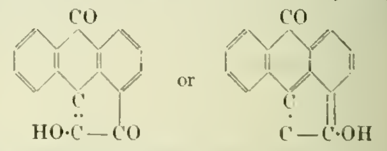
By treating anthraquinone with dimethylphenylbenzylammonium chloride ("Leucotrope") in the presence of caustic soda and sodium hydrosulphite, benzyloxanthrone,

$$\begin{smallmatrix}\mathrm{(C_6H_5.CH_2)}\\ \mathrm{HO}\end{smallmatrix}{>}\mathrm{C}{<}\begin{smallmatrix}\mathrm{C_6H_4}\\ \mathrm{C_6H_4}\end{smallmatrix}{>}\mathrm{CO},$$

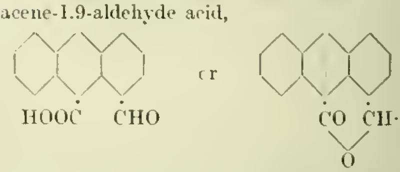
is formed—analogous to the formation of the benzyl ether of indigo in the "Leucotrope" discharge process, the reaction being a general one. On heating with sulphuric acid benzyloxanthrone loses water and gives the compound, $\mathrm{C_6H_5.CH : C}{<}\begin{smallmatrix}\mathrm{C_6H_4}\\ \mathrm{C_6H_4}\end{smallmatrix}{>}\mathrm{CO}$, m. pt. 117° C.—J. B.

Aceanthrenequinone ; The behaviour of —— with dilute alkali. C. Liebermann and M. Kardos. Ber., 1914, **47**, 1203—1210.

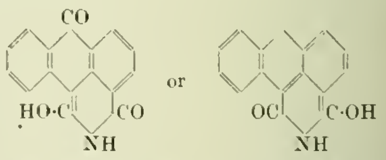
By boiling aceanthrenquinone with 10% caustic soda both hydrolysis and oxidation take place and the following products have been isolated : aceanthrenhydroxydione,



anthracene-1.9-aldehyde acid,



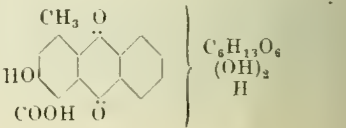
anthraquinone-1-carboxylic acid and anthracene-1.9-dicarboxylic acid-anhydride. Aceanthrenhydroxydione gives a phenylhydrazone and an oxime, the latter condensing when heated with strong sulphuric to anthronhydroxypyridone,



By submitting this substance to the caustic potash melt and oxidising the resulting leuco-compound, Iso-aceanthrene Green is obtained, a dyestuff dyeing cotton from the vat a violet shade changing to a dull green in the air.
—J. B.

Carminic acid. O. Dimroth. Annalen, 1913, **399**, 1—35.
(See also this J., 1914, 544)

Carminic acid, the dyestuff of cochineal, has been previously oxidised by the author (this J., 1909, 595) to carmazarin (8-methyl-2.3.6-trihydroxynaphthalene-5-carboxylic acid). Using hydrogen peroxide and caustic potash in the presence of a catalyst, an intermediate oxidation product has now been obtained which is shown to be 8-methyl-2.6-dihydroxy-1.4-naphthoquinone-3.5-dicarboxylic acid. On treatment with bromine this substance yields β-bromo-carmine, which therefore must be 8-methyl-2.6-dihydroxy-3.5.7-tribromo-1.4-naphthoquinone. The constitution of this new oxidation product indicates that carminic acid is a derivative of anthraquinone. The coccinine whic results from the fusion of carminic acid with causti potash has also been investigated and shown to be a derivative of anthranol. It oxidises in alkaline solutio in air to coccinone, a mordant dyestuff, which gives o further oxidation the known cochenillic acid (1-methyl-3 hydroxybenzene-4.5.6-tricarboxylic acid). On distillin carminic acid with zinc dust anthracene, α-methylanthra cene and possibly higher homologues are formed. Th constitution :



in which $C_4H_{13}O_4$ is probably an aliphatic residue, is suggested for carminic acid.—J. B.

Dihydroxy-1.4-naphthoquinones ; The 2.6 and 2.7- ——. O. Dimroth and B. Kerkovius. Annalen, 1913, **399,** 36—43.

The compounds mentioned in the title were prepared by Thiele's method by treating the known 6- and 7-hydroxy-β-naphthoquinones with acetic anhydride and sulphuric acid, saponifying the resulting tetracetyl-1.2.4.6- and -1.2.4.7-tetrahydroxynaphthalenes and then oxidising to the quinones (see Annalen, 1900, **311,** 341). The 2.6-isomeride gives the same colour reactions as the methyldihydroxynaphthoquinonedicarboxylic acid derived from carminic acid (see preceding abstract) and on bromination it gives a tribromo-derivative closely similar to β-bromocarmine. The 2.7-isomeride, on the other hand, gives different colour reactions from the oxidation product of carminic acid and its bromination product is quite different from β-bromocarmine. The identification of the oxidation product of carminic acid as 8-methyl-2.6-dihydroxy-1.4-naphthoquinone-3.5-dicarboxylic acid is thus confirmed.—J. B.

Kermes ; The dyestuff of ——. O. Dimroth and W. Scheurer. Annalen, 1913, **399,** I, 43—61

The dyestuff of kermes yields the same decomposition products as carminic acid, and like the latter gives α-bromocarmine when brominated in boiling 50% acetic acid. In anhydrous acetic acid however, the reaction does not go so far and there is obtained a new dyestuff, monobromococcin,  $C_6H(OH)(CH_3)(COOH)<{\substack{CO\\CO}}>C_6(OH)_3Br$. The side chain, C_2H_3O, of kermes acid is replaced in this bromination. As the original substance has no aldehyde properties, this side chain must be an acetyl group, whence it follows that kermes acid has the constitution  $(COOH)(CH_3)(OH)C_6H<{\substack{CO\\CO}}>C_6(OH)_3(C_2H_3O)$. Distillation of kermes acid with zinc dust gives α-methylanthracene. Kermes also contains a second dyestuff called flavokermes acid, which has different dyeing properties from the main constituent. Kermes wax consists of the ceryl ester of cerotinic acid.—J. B.

German dyestuffs and medicines ; Embargo on exports of ——. Oil, Paint. and Drug Rep., Sept. 14, 1914. [T.R.]

There is a general expectation that the German embargo on certain exports from that country *viâ* Rotterdam will soon be raised, and Mr. H. A. Metz, of New York, is said to have received advices that it had been raised on dyestuffs and most medicines (see however this J., 1914, 915). It is reported that German dyestuffs are very scarce in the United States. "Developed black," normally 24 c. per lb., was unobtainable under $2.00 per lb. in 20,000 lb. lots. "Oxidised black" had advanced from 8·5 c. to 50 c., carbolic crystals from 7.5 c. to 65 c., and tartaric acid from 29 c. to 85 c. In the case of potash salts used by lead glass manufacturers, not 60 days' supply remained in the country. Potassium chloride has advanced from $35 to $185 per ton. The State Dept. so far cannot indicate when foreign shipments will begin.

Patents.

Monoazo dyestuff ; Process for making a ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 468,218, Feb. 5, 1914. Under Int Conv., Sept. 1 and 2, 1913.

A dyestuff which gives red shades on wool very fast to light, is obtained by combining the diazo derivative of 4-acetaminoaniline-2-sulphonic acid with 2-amino-8-naphthol-6-sulphonic acid, or by acetylating the dyestuff obtained, for example, by alkaline reduction of the compound of *p*-nitraniline-*o*-sulphonic acid with γ-aminonaphtholsulphonic acid.—T. F. B.

Phthaleins of the naphthalene series ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 275,897, April 16, 1913.

1.6-Dihydroxynaphthalene is combined with phthalic anhydride or its substitution products, with or without addition of a condensing agent, *e.g.*, by heating on an oil-bath at 180°—200° C. The products are deep red substances, soluble in alkali, which dye deep bluish-green shades.—T. F. B.

Sulphide dyestuffs ; Process for preparing ——. R. Vidal Fr. Pat. 468,526, April 25, 1913.

Black or blue sulphide dyestuffs are obtained by heating *p*-aminophenol, *p*-phenylenediamine, *op*-diaminophenol, hydroxyazobenzene, benzene-azo-cresols, or polyamino- or aminohydroxydiphenylamines with sulphur in presence of phenol, cresol, or α- or β-naphthol. The dyestuffs from hydroxyazobenzene or hydroxyazotoluene are black : the rest are blue. The following example is given : A mixture of *p*-aminophenol (50 kilos.), sulphur (30 kilos.), and commercial cresol (100 kilos.) is boiled under a reflux condenser for 12 hours ; on treating the product with benzene the dyestuff separates as a powder. In cases where it is not desirable or possible to boil the mixture, *e.g.*, with the naphthols, it is heated to 200°—220° C.
—T. F. B.

Azo dyestuffs ; Process for preparing ——. L. Cassella und Co. Ger. Pat. 275,896, July 1, 1913.

A diazo or tetrazo compound is combined with triaminocarbazolemonosulphonic acid (see Ger. Pat. 275,975 ; this J., 1914, 854) ; when the product is diazotised and developed on the fibre or combined with a diazotised nitraniline, yellowish-brown to black shades, fast to washing and light, are produced.—T. F. B.

Vat dyestuffs ; Manufacture of ——. E. Wray, Assignor to Kalle und Co. Akt.-Ges., Biebrich on Rhine, Germany. U.S. Pats. 1,108,056 and 1,108,057, Aug. 18, 1914 ; dates of appl., Oct. 29, 1913.

See Ger. Pat. 269,123 of 1912 and Fr. Pat. 463,772 of 1913 ; this J., 1914, 247, 416.—T. F. B.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Solidonia [bast fibre]. R. Werner. Färber-Zeit., 1914, **25,** 284.

Solidonia is a bast fibre which furnishes a yarn of good tensile strength and high lustre. It is generally used mixed with wool or cotton. The fibre can be bleached and dyed just like cotton. Low temperatures are recommended for dyeing—not above 80°—90° C.—as the material becomes brittle at the boiling point. Drying at low temperatures is also necessary. The same dyestuffs are employed as for cotton.—J. B.

Patents.

Fabrics for outer covers for pneumatic tyres and envelopes for balloons ; Manufacture of ——. L. Liais, Paris. Eng. Pat. 22,065, Sept. 30, 1913. Under Int. Conv., Oct. 9, 1912.

The weft threads, preferably on cops unwinding from the inside (cocoon pirns), are impregnated with a rubber solution and woven while still wet, the material being afterwards vulcanised.—J. B.

Fur ; Art of carroting ——. P. C. Donner, Summit, N.J. U.S. Pat. 1,106,371, Aug. 11, 1914 ; date of appl., March 17, 1914.

The cut fur is blown into a receptacle at the top and a "carroting" solution is sprayed on to the moving fur.
—J. B.

Silk fibres; Process for strengthening —— and increasing their elasticity. E. Vowe. Fr. Pat. 467,987, Feb. 3, 1914.

Raw silk is treated in a bath of water to which is added a saponified drying oil, *e.g.*, linseed oil, and an "alkali," preferably Marseilles soap, and then dried in the air.—A. S.

Purification, decolorisation and disinfection of flax by means of sulphurous acid. A. Leconte. Fr. Pat. 468,312, Feb. 11, 1914.

The flax is treated with an aqueous solution of sulphurous acid and then washed repeatedly, the water being removed in a hydraulic press after each washing.—J. B.

Filaments, films and masses from cellulose acetate; Process of preparing ——. H. S. Mork, Assignor to Chemical Products Co., Boston, Mass. U.S. Pat. 1,107,222, Aug. 11, 1914; date of appl., March 27, 1914.

The cellulose acetate is dissolved in a solvent composed largely of acetylene tetrachloride and is coagulated by a mixture of acetylene tetrachloride with petroleum hydrocarbons the average boiling point of which is higher than that of the acetylene tetrachloride.—J. B.

Plastic material enclosed between two films of cellulose; New products composed of a —— and process of manufacture of same. J. E. Brandenberger. First Addition, dated Jan. 22, 1914, to Fr. Pat. 458,638, May 31, 1913 (this J., 1913, 1063).

One of the films of cellulose may be replaced by any material in web form, *e.g.*, metal foil, paper or fabric. One or more materials having continuous or discontinuous surfaces may be introduced between the two cellulose films at the same time as the plastic material and embedded in the same.—J. F. B.

Plastic material [from soy beans] capable of replacing celluloid, suitable for finishing, spinning and weaving; Transparent, flexible, non-inflammable ——. P. J. Contant and J. B. F. Perrot. First Addition, dated Jan. 5, 1914, to Fr. Pat. 461,007, Aug. 1, 1913 (this J., 1914, 20).

One hundred kilos. of soy beans are steeped in soft water for 18—24 hours, crushed and treated with sufficient water to give 500 litres of "milk." After filtration, the liquor is made slightly alkaline with ammonia, or preferably magnesia mixture, allowed to settle for 6 hours, decanted off and precipitated by acetic or nitric acid. The precipitate is washed, heated with a little water to 80°—100° C., filtered off, dried and powdered. The product is treated with a 10% solution of sodium phenoxide in the proportion of 1 grm. of phenoxide to 20 grms. of dry material. This solution is treated with 2% of alum on the dry weight and the precipitate collected and dried. The product is dissolved, milled, and compressed.—J. F. B.

Carbohydrates of the type $(C_6H_{10}O_5)_n$ and their derivatives; Manufacture of ethers of —— [for celluloid substitutes, artificial threads, etc.]. L. Lilienfeld. Fr. Pat. 468,162, Feb. 7, 1914. Under Int. Conv., Feb. 14, 1913.

Carbohydrates, other than cellulose, of the type $(C_6H_{10}O_5)_n$, or their derivatives, *e.g.* starch, dextrins, and the like, are treated with esters and alkalis in presence of suitable solvents or diluents, etherification being accelerated by catalytic, condensing or dehydrating agents. Or the carbohydrate, in alkaline solution, is partially etherified to produce ethers soluble in water, the product, previously isolated if desired, then being further etherified to form insoluble ethers. The products, alone or mixed with other agglutinants, plastic materials, etc., are employed for making celluloid and substitutes therefor, artificial thread, varnish, dressings for fabrics, printing compositions, glue, etc.—L. E.

Cellulose; Process for obtaining lustrous threads of a basis of ——. J. Joliot. Fr. Pat. 468,380, April 22, 1913.

Threads composed of natural cellulose fibres, *e.g.* hanks of cotton yarn, are converted into alkali-cellulose under tension as in the ordinary mercerising process; they are then subjected to the regulated action of cuprammonium solution or of carbon bisulphide without proceeding to the extent of dissolving the threads. The treated threads are stretched by tension to an extent depending on the degree of brilliancy desired and in this state are re-converted into cellulose and purified.—J. F. B.

Cellulosic substances; Conversion of —— into plastic or gelatinous masses or colloidal solutions. P. von Weimarn. Ger. Pat. 275,882, April 27, 1912.

Cellulosic substances are converted first into a gelatinous or plastic condition and finally into colloidal solutions, by heating them under suitable conditions with solutions of neutral salts, other than zinc salts, potassium and ammonium thiocyanate, potassium iodide, and potassium-mercuric or barium-mercuric iodide. When sodium iodide, calcium bromide or iodide, or barium, calcium, strontium, or sodium thiocyanate is used, the reactions can be carried out at atmospheric pressure. Sodium or potassium chloride and sodium sulphate involve the use of higher pressures. When "concentrated" sodium chloride solution is used, solution of the cellulose commences at about 170° C. at 8 atmos. The same solvent action is observed with nitrates, acetates, and many other salts.—T. F. B.

Paper machine; Arrangement for regulating the weight of pulp in the stuff-box of the ——. E. W. Rüdiger. Fr. Pat. 468,682, Jan. 31, 1914.

The stuff flowing from the chest into the stuff-box of the paper machine is regulated automatically, independently of the amount of stuff in the chest, by means of a lever or spring balance which can be set to admit any desired weight of pulp and which controls the buckets, valves or other devices by which the stuff is transferred from the chest. Various arrangements for carrying out this principle are described.—J. F. B.

Artificial silk and other similar articles of cellulose; Process for preparing —— from solutions of viscose. F. Petit, Lyons, France. Eng. Pat. 24,376, Oct. 27, 1913.

See Fr. Pat. 461,900 of 1912 and Addition thereto; this J., 1914, 196, 858.—T. F. B.

Nitrocellulose and similar substances; Making compounds of ——. D. Bachrach, Baltimore. Reissue No. 13,793, Sept. 1, 1914, of U.S. Pat. 794,581, July 11, 1905. Date of appl., Aug. 25, 1910.

See this J., 1905, 901.—T. F. B.

Cellulose acetate soluble in ethyl acetate; Process of making a ——. F. Collischonn, Frankfort, and F. Ruppert, Mainz-Mombach, Assignors to Verein f. Chem. Industrie in Mainz. Mainz, Germany. U.S. Pat. 1,109,512, Sept. 1, 1914. Date of appl., Feb. 18, 1913.

See Fr. Pat. 455,117 of 1913; this J., 1913, 865.—T. F. B.

Production of glucose and alcohol from sawdust and other cellulosic materials. Fr. Pat. 468,188. *See* XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Wool and indigo; A chemical compound obtained from ——. M. Fort and L. L. Lloyd. J. Soc. Dyers and Col., 1914, **30**, 297—298.

Indigo-dyed wool was extracted with boiling acetic acid and the extract diluted with water. A precipitate was formed containing wool substance and Indigo in fixed proportions. Similar results were obtained with other solvents and methods of isolation, and it is concluded that a definite wool-Indigo lake is formed on the fibre when wool is dyed with Indigo, which explains the superior fastness of Indigo dyed on wool to Indigo dyed on cotton. —J. B.

Bleaching of cotton cloth; Chemistry of ——. J. C. Hebden. J. Ind. Eng. Chem., 1914, **6**, 714—720.

Samples of cotton taken from goods being regularly bleached by the caustic soda boiling process were examined at different stages. The results given are :—

Percentages of original substances removed at the end of each operation.

	Steep.	First boil.	Second boil.	Chemick.	Sour.
	%	%	%	%	%
Ash	70·5	87·3	95·4	93·0	95·0
Proteins (N × 6·25)	—	91·5	91·7	92·2	92·7
Fats and waxes (ether extract)	5·5	20·4	64·0	67·8	69·6
Phosphoric acid	60·0	100·0	—	—	—

The samples were also submitted to wetting-out and steaming tests, and it is concluded that the yellowing produced by steaming is due to the proteins rather than to fats and waxes. It is suggested that the bleaching process be controlled by ultimate analyses of the cotton, checked by determinations of ash, and of ether and alcohol extracts. (See also Cross, this J., 1908, 260.)—A. S.

Patents.

Cotton; Process for imparting the character of wool to ——. Heberlein et Cie. Fr. Pat. 468,821, Feb. 23, 1914. Under Int. Conv., Dec. 5, 1913, and Feb. 13, 1914.

The cotton is mercerised, then treated with sulphuric acid of 49°—51° B. (sp. gr. 1·515—1·546), and finally washed. The acid may be printed to produce designs. Instead of sulphuric acid, phosphoric acid of 55°—57° B. (sp. gr. 1·615—1·652), hydrochloric acid of sp. gr. 1·19, nitric acid of 43°—46° B. (sp. gr. 1·424—1·468), zinc chloride solution of 66° B. (sp. gr. 1·842) at 60°—70° C., or an ammoniacal copper solution may be used.—J. B.

Bleaching or scouring fibrous materials; Apparatus for ——. J. Macadam, Chester, Pa., Assignor to the Eddystone Manufacturing Co., Eddystone, Pa. U.S. Pat. 1,107,160, Aug. 11, 1914.

The material is passed through the tank containing the liquor between two parallel endless belts which pass up and down the tank over guides and rollers placed at the top and bottom. The belts consist of rollers held in driving chains. The tank is enclosed and the endless belts enter and leave through waterseals.—J. B.

Bleaching of vegetable fibres; Process for facilitating the ——. E. T. J. Watremez. Fr. Pat. 467,887, Jan. 30, 1914. Under Int. Conv., Feb. 7, 1913.

Fibres difficult to bleach by the usual processes are treated first with an alkaline bath containing the salt of a metal the oxide of which is soluble in excess of alkali (preferably sodium aluminate) and then with an acid, after which the material is "chemicked" and the process, if necessary, repeated.—J. B.

Bleaching animal fibres by separate treatments with hydrogen peroxide and ammonia. Chem. Werke vorm. Dr. H. Byk. Ger. Pat. 275,879, May 27, 1911. Addition to Ger. Pat. 270,703.

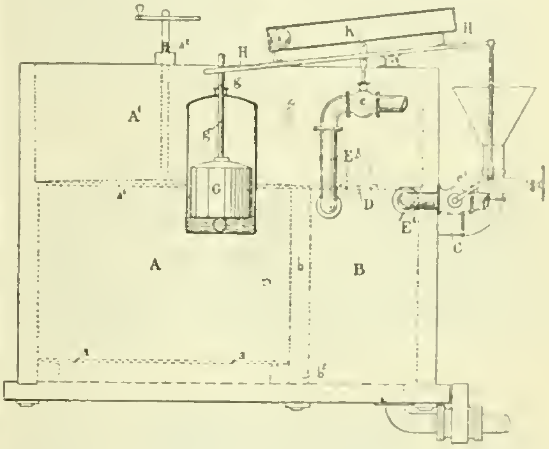
Wool, silk, feathers, and other animal substances may be bleached by the process described in the principal patent (see Eng. Pat. 6896 of 1913; this J., 1913, 1007) for treating vegetable fibres. When delicate materials are to be bleached, stronger solutions may be employed and the treatments correspondingly shortened.—T. F. B.

Bleaching or dyeing liquors; [Apparatus for] treating textile materials with ——. O. and E. H. Sumner, St. Margarets-on-Thames. Eng. Pat. 18,817, Aug. 19, 1913.

The material and the dyeing or bleaching liquor are enclosed in two compartments and submitted to varying air pressure from a pump which causes the liquor alternately to rise and fall within the compartments. The air pressure is automatically controlled within the compartments by floats, which act through external levers on a reversing valve.—J. B.

Dyeing; Apparatus for ——. S. J. Applegate, Kendal, Westmoreland. Eng. Pat. 15,595, Dec. 23, 1913.

The dyeing machine is divided into a dyeing compartment, A, and a dye reservoir, B, separated by a partition, *b*, the latter being provided with openings, b^2, for the passage of liquor. The compartment, A, has a perforated false bottom, *a*, and is closed by a perforated cover, a^1, held in position by a screw, a^2. The reservoir, B, is fitted, in the cover, with a mixing valve, D, opening downwards, and held normally in a closed position by a spring. The two compartments are filled with dye liquor, to the level of the cover, through the pipe, C, and steam is then admitted through the pipe, E, the valve, *e*, being opened, and the exit pipe, E^1, closed by the valve, e^1. The liquor is driven into A and acting upon the float, G, the connecting rod, *g*, is raised until the end of the lever, H, is above the horizontal position, when the lever is tipped over by the ball, *k*, in the tube, K, thus closing the valve, *e*, and opening the valve, e^1. The liquor, accumulated in A^1, returns through the perforated cover, a^1, and through the goods to be dyed, but part returns through the valve, D, thus ensuring thorough mixing of the liquor.—B. N.



Dyeing apparatus. J. Schmitz, Philadelphia, Pa., Assignor to Uniform Dyeing Machine Co. U.S. Pat. 1,105,845, Aug. 4, 1914; date of appl., May 31, 1913.

The dye vat is divided into two compartments in one of which the material is packed in horizontal, superimposed, perforated trays. At the bottom of this compartment is a branched circulating pipe which is in connection with the other, relatively smaller, compartment and with the source of supply of dye-liquor.—J. B.

Dyeing-machine; Beam ——. F. M. Morton, Phoenix, Ala., Assignor to W. H. Dismuke and H. L. Woodruff, Columbia, Ga. U.S. Pat. 1,107,095, Aug. 11, 1914; date of appl., Sept. 24, 1912.

The beam consists of a series of slats fixed in the beam-heads and an intermediate series of movable slats connected with reciprocating mechanism for moving them inwards or outwards beyond or within the circumference of the fixed slats.—J. B.

Dyeing and finishing animal fibres and tissues; Process for ——. R. Vidal. Fr. Pat. 468,525, April 25, 1913.

Hair is dyed on the skin by treating it first with bichromate and afterwards with a sodium sulphide solution of a sulphide dyestuff or of the chromogen described in Fr. Pat. 391,465 (condensation product of *p*-phenylenediamine and 2 mols. of phenol; this J., 1908, 1150).—J. B.

Designed effects on cotton; Production of ——. Heberlein et Cie. Fr. Pat. 468,642, Feb. 19, 1914. Under Int. Conv., Nov. 20, 1913.

Mercerised cotton is printed with sulphuric acid of more than 50·5° B. (sp. gr. 1·538) and then washed, or the cotton may be printed with a reserve and treated with the sulphuric acid.—J. B.

Reserving the silk in half-silk goods in dyeing with sulphide blacks; Process for ——. Farbwerk Mühlheim vorm. A. Leonhardt und Co., Ger. Pat. 275,886, Nov. 19, 1913.

A natural or artificial resin, which is soluble in alkali, is added to the dye-bath, in quantities of, say, 20 grms. per litre.—T. F. B.

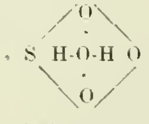
Metallic coatings upon cloth; Process for applying ——. J. Worsley, Blackpool, and C. Greenwood, Clifton Junction, Lancs. Eng. Pat. 17,871, Aug. 5, 1913.

A fabric suitable for optical projection screens is made by coating cloth (preferably coarse-grained American leather cloth) with a mixture of carriage varnish and boiled linseed oil and dusting it with a metallic powder.—J. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Sulphonic acids and —— *as hydrolytic agents: a discussion of the constitution of sulphuric and other polybasic acids and of the nature of acids. Studies of the processes operative in solutions. XXXI.* H. E. Armstrong and F. P. Worley. Proc. Roy. Soc., 1914, A **90**, 73—100.

The view is advanced that sulphuric acid is a monobasic acid, on the ground of its general behaviour, and particularly of the nearly equal hydrolytic activities of acid ethereal sulphates and the sulphonic radical in sulphonic acids, on the one hand, and of sulphuric acid, on the other. To it is assigned the formula:



The nearly equal velocity-constants obtained for the hydrolysis of sucrose in presence of different sulphonic acids show that the hydrolytic activity of the sulphonic radical is scarcely affected by the alterations in the hydrocarbon radical to which it is attached. The metabenzenedisulphonic acid is somewhat more active than the para, and much more active than the ortho acid. Benzene mono-, di-(meta), and tri-(1.3.5.-)sulphonic acids give equal activities in equivalent concentrations. Acidity is stated to be a function not of the hydrogen ion alone, but of the acid molecule as a whole, involving the co-operation of water. Two compounds are formed,

$$HX<^{H}_{OH} \text{ and } H_2O<^{H}_{X},$$

in proportions depending on the concentration: the discrepancy between the hydrolytic and electrolytic methods of contrasting acids may be explained on this basis.—O. E. M.

Sulphonic acids; The influence of sulphonates on the hydrolytic activity of ——: *a contribution to the discussion on the influence of neutral salts. Studies of the processes operative in solutions. XXXII.* H. E. Armstrong and F. P. Worley. Proc. Roy. Soc., 1914, A **90**, 101—111.

The increase caused by potassium toluene-*p*-sulphonate in the velocity-coefficient of hydrolysis of sucrose in presence of toluene-*p*-sulphonic acid is found to diminish with successive additions of the salt, and to fall to about a third of its value when the concentration is halved. The increase is greater the smaller the proportion of acid present. The addition of 1 equivalent of K, Ca, Sr, Ba, Zn, or Cd salts of toluene-*p*-sulphonic acid to solutions containing 1 molecular proportion of acid to 100 of water and 0·5 of sugar gives velocity-coefficients varying from 235 for the Ba-salt to 245 for the Zn-salt: the acid gives 217. The mechanism of hydrolysis is discussed in the light of the authors' association hypothesis.—O. E. M.

Borates; Electrolysis of fused ——. A. Zschille-Hartmann. Dissert., München, Techn. Hochschule, 1913, 1—61. Silikat-Zeits., 1914, **2**, 34—35.

By the electrolysis of fused borax, boron is produced near the cathode, but not at the anode as Moissan asserted. With high current-strengths veins of sodium are found in the separated boron (see Hampe, Chem.-Zeit., 1888, **12**, 841). The boron in the fused product was determined by oxidising it to boric acid and distilling this over as boric acid methyl ester. The constant fluctuation of the current strength is the chief difficulty in the electrolysis of borax. Iron and carbon anodes do not make effective contact with the fused borax and the best results were given by anodes made from a mixture of 80% of carbon powder and 20% of dehydrated powdered borax, made into a stiff paste with sugar, and moulded in an iron tube. Boron, nearly free from carbon, was obtained from pure borax with alternating current heating and a current density of from 0·45 to 0·8 ampère per sq. cm. It dissolved in water unless traces of an electrolyte were present. The air-dried product consisted of: B about 61%, and H_2O 14·3% with small quantities of C, Fe, and SiO_2, leaving a balance of O 14·4% possibly Weintraub's suboxide, B_6O (this J., 1910, 23).—W. C. H.

Silicic acid gels produced by the decomposition of silicates; Contribution to the knowledge of ——. M. Thiele. Dissert., Leipzig, 1913, 1—39. Silikat-Zeits., 1914, **2**, 33—34.

Silicic acids were obtained by decomposing fragments of natural heulandite and scolecite crystals with concentrated hydrochloric acid at 19° C. for several weeks, the gels being washed, dried and tested for purity. Gelatinous silicic acid separates in a few hours from scolecite and natrolite, and becomes mealy on drying, whereas the acid from heulandite and desmin is powdery and becomes granular on drying. With gels from the former minerals especially, distinct angular points often do not occur in the dehydration curves. The higher the temperature and the stronger the dehydrating agents employed, the larger are the amounts of water removed from the gels, which indicate that they are adsorption compounds of SiO_2 and H_2O. As Graham showed, the water of gels can be almost completely replaced by alcohol, acetic acid, glycerin and other substances, including chloroform and carbon tetrachloride, which not being miscible with water do not attract atmospheric moisture during the dehydration in air. Experiments with these liquids showed that there is a relation between their specific gravities and the amounts of liquid combined with the gel, though these are not in molecular ratios. The possibility of substituting other liquids for water in a gel without altering its properties indicates that the water of the hydrogel is not water of hydration. Silicic acid gels derived from simple artificial silicates such as those of lead and lithium had a water content of 26%, irrespective of their origin.—W. H. C.

Radium constants on the International Standard. E. Rutherford. Phil. Mag., 1914, **28**, 320—327.

Various radioactive magnitudes, determined in terms of the "Rutherford-Boltwood" standard, have been recalculated in terms of the International Standard. The revised values are :—(1) Amount of radium in equilibrium with 1 grm. of uranium, $3{\cdot}23 \times 10^{-7}$ grm. (2) Production of helium per grm. of radium per year, 164 cb. mm. (3) Total heating effect of 1 grm. of radium and its products in equilibrium with it, 134·7 cals. per hr. (4) Volume of emanation from 1 grm. of radium in equilibrium, 0·63 cb. mm. (5) Number of α particles expelled per sec. per grm. of radium itself, $3{\cdot}57 \times 10^{10}$; number per sec from 1 grm. of radium in equilibrium, $14{\cdot}3 \times 10^{10}$. (6) Total charge carried by the α particles per sec. from 1 grm. of radium itself and from each of its products in equilibrium with it, 33·2 e.s. units ; $1{\cdot}11 \times 10^{-9}$ e.m. units. (7) Total current due to the α rays from 1 curie of emanation (*a*) by itself, $2{\cdot}89 \times 10^{6}$ e.s. units, (*b*) with its α ray products, $9{\cdot}94 \times 10^{6}$ e.s. units. (8) Total charge carried by the β particles emitted per sec. by radium B or radium C in equilibrium with 1 grm. of radium, 18·3 e.s. units. (9) Calculated half value period of transformation of radium, 1690 years.—F. Sodn.

Nitrogen ; An oxidisable variety of ——. T. M. Lowry. Phil. Mag., 1914, **28**, 412—416.

Air which had been submitted successively to a silent and sparking discharge, as in Leetham's process for the preparation of bleaching gases for flour, etc. (this J., 1905, 341), was compared spectroscopically with that which had been passed through a silent discharge or spark-gap apparatus only. No visible absorption was observed except with the gas obtained by using both forms of discharge, with which the flutings characteristic of nitrogen peroxide could be clearly recognised. The proportion of peroxide (about 1/4000 by volume) was but little affected by passing the air through the ozoniser and spark-gaps in the reverse order, or by passing air partly through an ozoniser and partly through spark-gaps, and mixing the gases when no longer under the influence of the discharge. The spark discharge appears to lead to the production of an oxidisable variety of nitrogen (see also this J., 1912, 383) which, however, reverts in a few seconds to a form no longer oxidisable (either by oxygen or ozone), and it is suggested that the most important feature in the technical fixation of nitrogen may be the generation of this modified nitrogen, under conditions which provide a supply of atomic or ozonised oxygen to effect oxidation before reversion to the ordinary inactive form can take place. Strutt's chemically active nitrogen (this J., 1911, 683 ; 1912, 70) is not oxidisable by ozone under the conditions of his experiments. The paper is illustrated by photographs of spectra.—F. Sodn.

U.S. bauxite and aluminium in 1913. W. C. Phalen. U.S. Geol. Survey, Sept., 1914. [T.R.]

The production of bauxite in the United States in 1913 was 210,241 long tons, valued at \$997,698, an increase of 31·5% in quantity over that of 1912 and of 29·8% in value. Arkansas led, and the production of Tennessee showed an increase. The falling off in Alabama was considerable. During the year the demand for aluminium has shown a steady growth, and although the statistics of production are not complete, it is known that 72,379,000 lb. were consumed in 1913 in the United States.

Heavy chemicals. Board of Trade Bulletin.

A Bulletin (No. 67) on heavy chemicals has been issued by the Board of Trade ; it covers the following products :—Aluminous sulphates (including alums) : arsenic and its oxides and compounds : bleaching materials : coal products, not dyes ; copper sulphate ; potassium and sodium cyanides ; soda compounds ; sulphuric acid.

Inquiries should be addressed to the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, London, E.C.

Patents.

Acetic acid ; Manufacture of ——. Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst a Main, Germany. Eng. Pat. 10,377, April 27, 1914. Under Int. Conv., April 26, 1913.

Acetaldehyde, mixed with about 1% of its weight of a catalyst, especially ceric oxide, is treated with oxygen under a pressure of about 2 atmospheres, or with air at a somewhat higher pressure, for 5 hours, cooling being resorted to after the temperature rises spontaneously to 50°—60° C. ; 95% of the theoretical amount of glacial acetic acid is thereby produced.—O. R.

Acetic acid ; Process of producing ——. E. H. French, Dayton, and J. R. Withrow, Columbus, Ohio. U.S. Pat. 1,104,978, July 28, 1914 ; date of appl., July 9, 1909.

Crude acetic acid is subjected to electrolysis in conjunction with a salt to remove pyroligneous substances and foreign volatile acids ; the electrolysis is regulated so that no material decomposition of acetic acid takes place.—O. R.

Nitrogen ; Process for fixing —— *by means of ferro-aluminium.* Soc. Générale des Nitrures, Paris. Eng. Pat. 27,971. Dec. 4, 1913. Under Int. Conv., Nov. 19, 1913. Addition to Eng. Pat. 27,030, June 7, 1913 (this J., 1914, 549).

In carrying out the process described in the principal patent, it may suffice to start the reaction at one or more points, and allow the reaction to be propagated throughout the whole mass by the heat so evolved. The ferro-aluminium may be used in the form of powder, agglomerates, or packets wrapped in paper, and may contain a small percentage of activating agents, especially aluminium fluoride or carbide.—O. R.

Magnesium perborate ; Manufacture of ——. Henkel und Co., Düsseldorf, Germany. Eng. Pat. 3388, Feb. 9, 1914. Under Int. Conv., Feb. 19, 1913.

One molecular proportion of crystallised magnesium sulphate and two mol. proportions of sodium perborate ($NaBO_3,4H_2O$) are melted together at 65°—70° C., kept at that temperature for some time with stirring, cooled, and the solidified mass pulverised.—O. R.

Sulphur dioxide ; Apparatus for making ——. J. G. Jones, Carthage, N.Y. U.S. Pat. 1,097,177, May 19, 1914 ; date of appl., Sept. 25, 1911.

A rotary kiln for burning pyrites, mounted at a slight inclination, is provided near its exit with a sulphur-burner, to furnish heat for starting the decomposition of the ore, the vaporised sulphur passing through a central tubular duct between which and the inner circumference of the kiln are radial partitions ; the partitions and duct terminate in a small chamber, which forms part of the burning zone. Between this chamber and the inlet of the kiln is a second series of radial partitions. A screw conveyor at the inlet end feeds the ore forward into the kiln. At the exit of the kiln is a discharge hood having a closed end with peep holes, and a door, which automatically opens and shuts as the kiln rotates, thereby discharging the spent pyrites.—O. R.

Salt ; Process of making ——. C. L. Weil, Assignor to Diamond Crystal Salt Co., St. Clair, Mich. U.S. Pat. 1,105,387, July 28, 1914 ; date of appl., May 31, 1911.

Brine is superheated in stages, and is passed from below upwards through pressure-releasing devices at different levels, the vapours escaping when the pressure is released, serving to heat the brine in the earlier stages of the process. The mother liquors mixed with fresh brine are thus heated to 260° F. (126·6° C.) and then cooled to 245° F. (118° C.), the impurities deposited at each of these temperatures are removed, and the brine is admitted to the evaporating pans at 226° F. (108° C.) and at atmospheric pressure, to deposit salt in granular form.—O. R.

(a) *Titanic oxide concentrate and method for producing the same.* (b and c) *Methods for concentrating titanic oxide from substances containing it and iron oxide.* (d and e) *Methods of obtaining titanic oxide.* A. J. Rossi and L. E. Barton, Niagara Falls, N.Y., Assignors to The Titanium Alloy Manufacturing Co., New York. U.S. Pats. 1,106,406—1,106,410, Aug. 11, 1914 ; dates of appl., (a, b and c) Nov. 29, 1912, (d and e) Feb. 6, 1913.

(a) Ore containing TiO_2 and iron oxide is smelted with caustic alkali (*e.g.*, sodium hydroxide), in presence of a reducing agent, the melt—containing alkali titanate and metallic iron—is lixiviated with hot water, and the undissolved residue treated with sulphuric acid to dissolve the titanium compounds, which are then precipitated (preferably by boiling the solution with nitric acid) and calcined. (B) After smelting as above, in the presence of a reducing agent (carbon, for example), withdrawing iron from the melt, and lixiviating with water, the insoluble portion is treated with an iron-solvent acid, such as sulphuric acid, so diluted as to dissolve the compounds present other than titanic oxide. (C) The ore is melted with caustic alkali, the melt lixiviated with hot water, and the undissolved portion treated with acid, diluted so as to dissolve iron rather than titanium compounds, the residue being ignited. (D) The ore is fused with alkali sulphide (*e.g.*, sodium sulphide) and the melt treated as in C, the residue insoluble in water being boiled with the dilute acid. (E) Carbon and an alkali sulphate are substituted for the alkali sulphide in D.—F. Sodn.

Barium hydrate [hydroxide]; Process of making ——. S. B. Newberry and H. N. Barrett, Baybridge, Ohio. U.S. Pat. 1,106,578, Aug. 11, 1914; date of appl., April 19, 1912.

Barium sulphate is mixed with an infusible insoluble material and the finely divided mixture (90% of which should be capable of passing through a 100-mesh screen) heated, in an agitated condition, to not below 2700° F. (1482° C.), or until substantially all the sulphate is converted into oxide. Barium hydroxide is obtained from the calcined product by treatment with water.—F. Sodn.

Argon and rare atmospheric gases; Method of obtaining ——. J. E. Bucher, Coventry, R.I., Assignor to Nitrogen Products Co., Providence, R.I. U.S. Pat. 1,106,921, Aug. 11, 1914; date of appl., Dec. 15, 1913.

Atmospheric nitrogen, substantially free from oxygen, is passed at from 500°—1150° C. through a heated mass presenting an extended surface of catalytic material intimately associated with carbon and free alkali metal (or other element capable of acting as the base of a stable cyanogen compound), with which the nitrogen combines. —F. Sodn.

Potassium compounds from silicious minerals; Process of extracting ——. T. B. Stillman, Hoboken, N.J. U.S. Pat. 1,106,984, Aug. 11, 1914; date of appl., March 29, 1913.

The finely divided mineral is fused with potassium carbonate, to convert the silica into potassium silicate, the ground product treated with cold water to dissolve the potassium aluminate and potassium oxide, and ammonia and an ammonium salt added to the solution to precipitate the aluminium as hydrated oxide, which is separated from the liquor. The solution is then treated with carbon dioxide to convert potassium hydroxide into carbonate, and evaporated. The residue insoluble in cold water is also treated for the recovery of potassium. —F. Sodn.

Nitrogen and carbonic acid; Process for obtaining ——. Nitrogen Ges. m. b. H. Fr. Pat. 468,349, Feb. 12, 1914.

In the preparation of nitrogen and carbon dioxide by passing air or gaseous products of combustion over a heated mixture of copper and copper oxide, this mixture is incorporated with aluminium hydroxide, silicic acid, or calcium oxide, to allow of the reaction being carried out at a much lower temperature and thus prevent sintering. —F. Sodn.

Ammoniacal liquor; Process for the complete extraction of industrial chemical products contained in crude ——. L. C. Bonneau and V. E. Hasenfratz. Fr. Pat. 468,535, April 26, 1913.

The liquor is distilled and sulphur extracted from the residue by a volatile solvent (preferably trichloroethylene, in the apparatus described in Fr. Pat. 457,905 of 1913; this J., 1913, 999), the residue is first exhausted with water to which the ammoniacal distillate from the first operation is added, the resulting solution of ammonium salts being distilled with lime, and then treated with lime and water, whereby Prussian blue is converted into soluble calcium ferrocyanide: potassium chloride is added to the ferrocyanide solution to precipitate the double ferrocyanide of calcium and potassium, and this is converted by sodium carbonate into potassium sodium ferrocyanide which is treated with a ferric salt to obtain pure Prussian blue. —F. Sodn.

Calcium cyanamide; Processes and furnace installation for the manufacture of ——. J. H. Lidholm and Dettifoss Power Co., Ltd. Fr. Pats. (A) 469,045 and (B) 469,046, Feb. 12, 1914. Under Int. Conv., Feb. 18, 1913.

(A) Nitrogen, under pressure, is brought into contact with heated calcium carbide, to which is added an inert heat-absorbing substance, such as sand, to prevent fusion or sintering of the material. (B) Finely divided calcium carbide and nitrogen are brought together at a temperature at which reaction is instantaneous, sintering of the material being avoided by preventing the grains from coming together until sufficiently cooled. In the apparatus described the powdered carbide falls through a sieve into a chamber heated electrically by resistance, and the product is suddenly chilled below its dissociation temperature by passing into a zone surrounded by a cooling device.—F. Sodn.

Iodine; Apparatus for the sublimation of ——. L. Le Gloahec. Fr. Pat. 469,118, Feb. 28, 1914.

The iodine is heated in a vessel having a double bottom into which steam is admitted tangentially.—F. Sodn.

Calcium cyanamide; Process of producing ——. Dettifos Power Co., Ltd., and J. H. Lidholm, London. Eng Pat. 3547, Feb. 11, 1914. Under Int. Conv., Feb. 18 1913.

See Fr. Pat. 469,046 of 1914; preceding.—T. F. B.

[Zinc] Sulphate liquors; Process for the electrolysis an treatment of ——. E. J. Hunt, Oldbury, and W. T Gidden, Warley, Assignors to Chance and Hunt, Ltd. Oldbury. U.S. Pat. 1,107,309, Aug. 18, 1914. Date o appl., March 21, 1914.

See Eng. Pat. 11,634 of 1913; this J., 1914, 692.—T. F. B

Hydrogen peroxide; Manufacture of ——. H. Henk and W. Weber, Assignors to Henkel und Co., Dusseldor Germany. U.S. Pat. 1,108,752, Aug. 25, 1914, Dat of appl., June 16, 1913.

See Eng. Pat. 8890 of 1913; this J., 1913, 791.—T. F. B

Perborates; Process for making ——. Henkel und C Fr. Pat. 468,293, Feb. 10, 1914. Under Int. Conv Feb. 19, 1913.

See Eng. Pat. 3388 of 1914; preceding.—T. F. B.

Hydrogen; Generation of —— *by means of iron.* Messerschmitt, Stolberg, Germany. U.S. Pat. 1,109,44 Sept. 1, 1914. Date of appl., June 26, 1912.

See Eng. Pat. 12,117 of 1912; this J., 1912, 1079.—T. F.

Hydrogen; Manufacture of ——. A. Messerschmit Stolberg, Germany. U.S. Pat. 1,109,448, Sept. 1, 1914 date of appl., March 14, 1913.

See Fr. Pat. 461,480 of 1913; this J., 1914, 201.—T. F.

Recovering as an ammonium salt the nitrogen of the hydr cyanic acid in crude coal gas. Eng. Pat. 29,047. *See* II

Patent Case.

Compounds containing unstable oxygen (hydrogen peroxide, etc.): Process for increasing the keeping qualities of ——. L. Sarason, Berlin. Eng. Pat. 23,676 of 1908 (this J., 1910, 152). Sarason v. Frenay. Repts. of Patent Cases, Vol. XXXI., 111. Official J. Patents., June 17, 1914, 252, and Aug. 12, 1914, 330. By permission.

This was an action for infringement. The patentee claimed the use of alkali pyrophosphate for increasing the keeping qualities of hydrogen peroxide, and inserted in his contracts a condition that all licensees should purchase from him all the pyrophosphates which they used in their hydrogen peroxide baths. The defendant contended that this condition was null and void and relied on the Patents and Designs Act, Section 38 (4).

The court held that pyrophosphate was not protected by the patent and that the condition inserted in the contract was unlawful. The decision was in favour of the defendant on both points.

VIII.—GLASS; CERAMICS.

Refractory clays: Effect of graphite on ——. F. Schreiber. Brick and Clay Record 1913. Silikat-Zeits., 1914, 2, 60.

A brick from a coke-oven which had cracked owing to the formation therein of free carbon contained :—

	Outer layer, clay. 45 mm. thick.	Middle dark layer. 22 mm. thick.	Inner, un-attacked layer. 12 mm. thick.
SiO_2	83·77	80·00	83·35
Al_2O_3	12·69	11·08	12·73
Fe_2O_3	1·16	0·67	1·15
CaO	0·24	0·23	0·23
MgO	0·42	0·29	0·32
K_2O	1·56	1·58	2·01
C	0·26	6·15	0·21
	100·10	100·00	100·00

Silica bricks may be destroyed in a similar manner. —W. C. H.

Clays: The rational analysis of ——. J. Burian and J. Juránek. Chemické listy 1912, [1—5.]. Silikat-Zeits., 1914, 2, 12—13.

Experiments were made on the effect of concentration and of the time of digestion at the boiling point with sulphuric acid on the decomposition of the clay substance; the effect of sulphuric acid at different concentrations on felspars and mica; the effect of lyes on felspars; the effect of hydrochloric acid on the clay substance and felspars; and the oxidation of organic substances in clays by chromic acid. The following improved process was devised: 3 grms. of clay, dried at 120° C. are heated in a covered porcelain dish for 6 to 8 hours with 25 c.c. of concentrated sulphuric acid, till white fumes appear. When cool, the liquid is diluted with hot water and decanted three times, the decanted liquid being collected in a 2 litre cylinder. The residue is boiled for 5 mins. with 25 c.c. of a mixture of equal parts of 5% NaOH and 5% Na_2CO_3 solution, then diluted with water, the residue washed twice by decantation, and boiled for 5 mins. with 10 c.c. of concentrated hydrochloric acid. The treatments with alkali and acid are repeated, the decanted liquid being united with that collected previously, and the residue then washed on a filter with dilute hydrochloric acid. The combined decanted liquids are allowed to stand 12 hours, the clear portion siphoned off, and the residue twice boiled for 5 mins. with alkali and acid, and brought on to the same filter. After igniting and weighing, the residue is decomposed with hydrofluoric and sulphuric acids, and the quantity of felspar in it calculated from the alumina. Any considerable quantity of organic matter can be removed by gradually heating the clay in the presence of dilute sulphuric acid (1 : 2) and adding chromium trioxide. The oxidation is completed in 5 mins., and after the clay has settled the green liquid is decanted, the residue washed with hot water, and the rational analysis carried out as above.—W. C. H.

Stoneware bodies; The casting of ——. H. Stein. Keram. Rundschau, 1913, 501. Silikat-Zeits., 1914, 2, 41—42.

To obtain a good casting body, 1 litre of the slip should weigh 1809—1813 grms., and difficulties arise when these limits are departed from even to a small extent. If the slip is only a little lighter, the piece splits in the mould; if heavier, the slip does not pour easily, and sound pieces taken from the mould split as soon as drying begins. This applies equally to stoneware bodies with a very large or very small content of non-plastic materials. An increase or decrease of the alkali added does not alter the behaviour of the mass on casting.—W. C. H.

Stoneware; Casting-flaws in ——. C. Tostmann. Keram. Rundschau, 1913, 535. Silikat-Zeits., 1914, 2, 19—20.

Casting-flaws appear as dark-coloured patches which do not take the glaze. They may be avoided by smearing the parts of the mould which are struck by the casting slip and by smoothing the surface of the white hard sherd. It should be possible to prevent their formation by pouring the slip on to a brass plate hung in the mould, but generally the slip is directed on to a place where the flaws are not objectionable. The flaws are probably caused by the splashing of the casting slip; the non-plastic material is thrown off, but the plastic clay adheres to the mould and forms a thin skin at the casting inlet.—W. C. H.

Stoneware; Casting-flaws in ——. H. Stein and C. Tostmann. Keram. Rundschau, 1914, 11. Silikat-Zeits., 1914, 2, 42.

According to Stein flaws may occur even when the stream of slip is carried to the bottom of the moulds through a funnel in such a way that splashing is prevented (see preceding abstract). The prevention of flaws in many bodies by the addition of water-glass is attributed by Tostmann to the separation of gelatinous silicic acid, which envelopes the non-plastic components, and prevents their being thrown back on striking the mould.—W. C. H.

Patents.

Alumina; Method of bonding fused crystalline ——. *Refractory article and method of manufacturing the same.* T. B. Allen, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pats. (A) 1,107,011 and (B) 1,107,012, Aug. 11, 1914; dates of appl., March 11 and Nov. 13, 1913.

(A). The alumina is mixed with a glycerin solution of boric acid or other acid, the radical of which is capable of combining with alumina, then moulded and heated to 1300° C. or higher. (B). Crystalline alumina is mixed with aluminium hydroxide, with or without addition of glyceroboric acid, then formed into the desired shape, and heated to a temperature (at least 1200° C.) sufficient to set the amorphous alumina.—A. S.

Furnaces for melting or smelting glass, metal, and ores: Liquid fuel ——. R., G., and K. H. Siegwart, Lucerne, Switzerland. Eng. Pat. 19,670, Aug. 30, 1913. Under Int. Conv., Feb. 17, 1913.

See Fr. Pat. 462,684 of 1913; this J., 1914, 342.—T. F. B.

Quartz bodies; Method of producing hollow ——. A. Voelker, Beuel, Germany. U.S. Pat. 1,107,386, Aug. 18, 1914. Date of appl., Aug. 13, 1909.

See Eng. Pat. 18,713 of 1909; this J., 1910, 89.—T. F. B.

Quartz: Method of producing transparent ——. A. Voelker, Beuel, Germany. U.S. Pat. 1,107,387, Aug. 18, 1914. Date of appl., Feb. 18, 1911.

See Fr. Pat. 421,526 of 1910; this J., 1911, 424.—T. F. B.

Brick kilns. W. Drayton, Shawnee, Ohio, U.S.A. Eng. Pat. 21,289, Sept. 20, 1913.

See U.S. Pat. 1,075,904 of 1913; this J., 1913, 1055.—T. F. B.

Enamel; Process of producing an opaquing agent for white ——. I. Kreidl, Vienna. Reissue No. 13,791, Aug. 25, 1914, of U.S. Pat. 1,024,405, April 23, 1912. Date of appl., Oct. 29, 1912.

Treatment of plastic materials [clay, soap, etc.]. Fr. Pat. 468,002. *See* I.

IX.—BUILDING MATERIALS.

[Portland cement.] Synthetic celite and large crystals of tricalcium silicate. E. D. Campbell. J. Ind. Eng. Chem., 1914, **6**, 706—710.

Finely-ground mixtures of washed kaolin, pure alumina, and pure calcium carbonate in proportions corresponding to the composition of celites recovered from cement clinker (this J., 1914, 25) were fused in a large platinum crucible, the furnace being heated to over 1150° C. during one night, and for 2—3 hours at 1585°—1590° C. on the following morning, then the temperature lowered to about 1415° C. during 4—6 hours, the burner removed, and the furnace closed and allowed to cool slowly: in some cases the furnace was closed and allowed to cool slowly from the highest temperature attained. The hard vitreous products contained well-defined crystals; they possessed hydraulic properties and in some cases test-pats gave perfect boiling tests. To isolate the crystals, pieces of the product were heated to 1590° C. in a magnesia dish supported on discs of magnesia: the fusible solvent (celite) was absorbed by the magnesia. The crystals (alite) thus obtained, some of which were nearly 7 mm. long, consisted mainly of $3CaO_2,SiO_2$ and analysis of the magnesia discs showed that the absorbed celite was mainly $5CaO,3Al_2O_3$ (see Shepherd and others, this J., 1911, 543). The view put forward previously (this J., 1914, 25) as to the constitution of celite is thus confirmed, and the aluminate is shown to be $5CaO,3Al_2O_3$. Based on the results, the general formula $x(3CaO,SiO_2)+y(5CaO,3Al_2O_3)$ is suggested for Portland cement. This formula, which requires a quantity of CaO equal to $2{\cdot}8SiO_2+0{\cdot}9Al_2O_3$, conforms more closely than those of Le Chatelier and Newberry (this J., 1897, 887) with the results obtained in the best practice.—A. S.

Portland cement, iron-Portland cement and blast-furnace slag; The hydration of ——. F. Blumenthal. Dissert., Jena, 1912, 1—46. Silikat-Zeits., 1914, **2**, 43—44.

Compounds formed by hydration in Portland cement can be identified by colour reactions. A solution of Anthrapurpurin in lime water gives a superficial red colour with lime and its compounds, when alumina is not present, and also colours alumina brownish-red. Alumina and its compounds, when freshly produced by hydrolysis, are coloured blue by Patent Blue, whilst ignited alumina, clay or alumina in acid solution are not coloured. Free silicic acid can be detected by a neutral solution and combined silicic acid by an acetic acid solution of Methylene Blue. The quantitative composition of the hydration products was adduced by comparison with artificially prepared melts. Experiments with calcium ferrites and ferrous silicates showed that the chief hydration products in Portland and iron-Portland cement are small hexagonal plates of tricalcium aluminate, fine needles of monocalcium silicate, a gelatinous mass of monocalcium silicate and large hexagonal crystals of calcium hydroxide. Iron shares in the hydration, forming ferrous silicates and tricalcium ferrite. The effect of water is not merely to hydrate compounds already present, but to produce new compounds from the individual components which occur in the uncombined condition in the clinker. Crystals of calcium silicate and tricalcium aluminate are first formed by hydration, and afterwards, a gelatinous mass of calcium silicate separates. The setting of cement is chiefly influenced by crystallisation processes. The actual hardening process occurs when these are complete and results in the binding together of the individual crystals and undecomposed grains of clinker and the filling of the pore spaces. Crystal and gel formation in cements is only possible when an excess of lime is present.—W. C. H.

Concrete: Tar painting of ——. B. N. Abbott. Eng. Record; through J. Gas Lighting, 1914, **127**, 663.

Asphaltum will not firmly adhere directly to concrete, but if the concrete surface be first painted with coal tar, the asphaltum will adhere so firmly that it cannot be broken away without bringing pieces of concrete with it. The coal tar should be heated in small quantities, just to the boiling-point, and then applied immediately.

Patents.

Slag; Treatment of —— *for the manufacture of bricks.* W. E. Evans, London. From E. R. Sutcliffe, Brussels. Eng. Pats. 18,806, and 7027, Aug. 19, 1913 and March 19, 1914.

The molten slag is granulated by running it into a thick mixture of lime and water, to which ground slag may be added. The mixture is afterwards conveyed to a sump or reservoir for the separation of the heavier particles of slag, the lighter particles passing away with the liquid mixture. The slag, being coated with lime, is in a suitable condition, after drying, for compression into bricks.—B. N

Water and weather proofing agent for porous stone and th like. H. von der Heide, Unna-Königsborn, Germany Eng. Pat. 10,491, April 28, 1914.

A mixture of an ammoniacal or alkaline solution of th hydroxides of Zn, Cu, Pb, Sn, Cr or Al, with a soa solution.—O. R.

Cement structure; Coloured —— *and process of makin same.* H. A. Gardner, Washington, D.C. U.S. Pa 1,106,298, Aug. 4, 1914; date of appl., Oct. 30, 1913.

A pigment, an aqueous solution of a resin soap, and calcareous cement are mixed and allowed to harden.—O. I

Cement or hydraulic lime; Process and apparatus f manufacture of ——. L. P. Basset. Fr. Pat. 466,51 March 4, 1913.

Plaster is decomposed by heating with clay and carbo so that the calcium sulphide formed reacts further wi the sulphate to form sulphur or sulphur dioxide, accordi to the equations: $3CaSO_4+CaS=4CaO+4SO_2$ a $SO_2+2CO=2CO_2+S$. Excess of calcium sulphide then destroyed by oxidation, if desired by an air blast. furnace for the process comprises two zones, with a reduci and oxidising atmosphere respectively, the former bei obtained by means of carbon monoxide or by injecti powdered carbon with the air.—H. H. S.

Lime; Process for obtaining a substance which increases hydraulic properties of ——. Alpine Maschinenfabriksg m. b. H. vorm. Holzhauer'sche Maschinenfabrik G m. b. H. and F. Meyer. Fr. Pat. 466,859, Dec. 27, 19 Under Int. Conv., Feb. 8, 1913.

A mixture of clay and limestone, dolomite, marl or the li containing 25—50% $CaCO_3$, together with a flux, *e.g.*, of calcium chloride, is heated to 800° C. The product w finely ground has only weak hydraulic properties but markedly increases the hydraulic properties of lime. A mixture of 25 parts of it with 75 parts each of lime and sand is recommended.—A. S.

Cement; Process for the manufacture of white ——. A. Helbronner. Fr. Pat. 468,527, April 25, 1913.

A white cement is produced from ferruginous raw materials by adding calcium chloride to them and then passing steam over the mass, raised to a high temperature. The process is facilitated by adding carbon or some other reactive substance to the raw materials, and in this case hydrochloric acid may be collected as a by-product. By heating alkali-felspars in the presence of carbon and calcium chloride, and passing steam over the mass, raised to a high temperature, calcium silico-aluminates of the same type as cement, and sodium and potassium compounds, which can be advantageously extracted, are produced. —W. C. H.

Concrete and mortar; Manufacture of impermeable and elastic —— requiring no expansion joints. R. Houben. Fr. Pat. 466,878, Dec. 31, 1913. Under Int. Conv., Nov. 19, 1913.

An elastic and noiseless concrete consists of 125 parts of cement, 200 of sand, 400 of small stones and 60 of an elastic material composed of: wood shavings or cotton waste 100, cork 100, oil 25, and bitumen 5 parts.—H. H. S.

Cement and materials similar to mortar; Process for the manufacture of ——. A. Anker. Fr. Pat. 469,149, March 2, 1914.

Before the final grinding the burnt clinker is brought into contact with steam, or with air charged with aqueous vapour, in order to slake the free lime, and to break the clinker into fragments. After the treatment with steam, the slaked lime can be separated by bolting before the final grinding.—W. C. H.

Retarder for plaster. Process of making a retarder for plaster and the like from lime wastage. C. H. Campbell, Chicago, Ill., Assignor to American Glue Co., Boston, Mass. U.S. Pats. (A) 1,106,777 and (B) 1,106,778, Aug. 11, 1914; dates of appl., May 12 and Oct. 18, 1910.

(A). The retarder is composed of lime wastage from the liming of hides, practically free from inert, insoluble animal matter and substances having objectionable odours, but containing a soluble albuminate, *e.g.*, "dissolved hair" (see U.S. Pat. 1,106,779; page 975). (B). The retarder is prepared by digesting lime wastage from the liming of hides with a suitable alkaline solution until the insoluble animal matter has been converted into soluble substances, and drying the resulting product.—A. S.

Mortar for construction or other works; Manufacture of an isolating material or ——. R. Varret and J. Ostrowski. Fr. Pat. 466,867, March 15, 1913.

A mixture, in variable proportions, of sodium palmitate, silica and sodium borate, is added to mortar or one of its components before or during gauging.—H. H. S.

Artificial stone and the like; Manufacture of —— from peat. W. Weiler. Fr. Pat. 467,337, Jan. 15, 1914. Under Int. Conv., Jan. 16, 1913.

The peat is gathered during the autumn and winter and stacked in the open air so that the water present therein becomes frozen. Ultimately it is dried, reduced to pulp, and compressed into blocks, with or without the addition of cement or other binding agent.—A. S.

Fireproof and heat-resisting material; Preparation of a ——. L. Esselborn. Fr. Pat. 467,393, Jan. 17, 1914.

A porous refractory material such as pumice stone is impregnated with milk of lime, and the particles are then enveloped in a protecting material such as a mixture of clay, sand, cement and trass.—H. H. S.

Heat-insulating materials and process for the manufacture of the same. Armstrong Cork Co. Fr. Pat. 468,938, Feb. 25, 1914.

A mixture of 60 to 80% of calcium fluoride and 12 to 25% of slaked lime with sufficient water to make a liquid paste is poured into moulds. The latter are shaken to facilitate the escape of air bubbles and to render the mass homogeneous and then dried and hardened without pressure. The moulds are coated inside with a mixture of water and magnesia to facilitate the removal of the blocks. —W. H. C.

Wood; Impregnation of coloured or soft —— at a high temperature without destroying the wood. L. Petersen-Hviid. Fr. Pat. 466,768, Dec. 30, 1913. Under Int. Conv., Dec. 30, 1912.

The acid compounds formed in wood at high temperatures are neutralised by ammonia, which is partly introduced into the wood before heating, and partly into the receiver continuously during heating. Ammonium salts thus formed in the wood are expelled by heat into the receiver, where they are decomposed by the introduction at intervals of soda lye or other non-volatile alkali, the process being thus regenerative.—H. H. S.

Woods; Process of hardening and preserving —— with a view to increasing their resistance and life. Comp. Française d'Injection pour la Conservation des Bois et des Tissus. Fr. Pat. 467,926, Jan. 24, 1914.

A hardening and preservative material, such as naphthalene, which is solid at ordinary temperatures is melted and the wood immediately impregnated with it. The process is specially applicable to paving blocks, sleepers, etc. By solidifying in the wood, the naphthalene equalises and increases the resistance and renders the wood uniformly hard.—W. C. H.

Wood; Process for impregnating —— and an apparatus for carrying out the process. Hulsberg und Co., m. b. H. Fr. Pat. 468,351, Feb. 12, 1914. Under Int. Conv., Oct. 24, 1913.

In order that wood may absorb an impregnating liquid better, it is perforated by means of needles. The needles are guided between plates provided with grooves, and are forced into or withdrawn from the wood by punches which are likewise guided between the plates. The lower ends of the punches are slotted in such a manner that they will hold and retain the needles during both the upward and downward movements.—W. C. H.

Cement or hydraulic lime; Process and apparatus for the manufacture of ——, *with the simultaneous production of sulphurous anhydride or of sulphur.* L. P. Basset, Montmorency, France. Eng. Pat. 17,873, Aug. 5, 1913. Under Int. Conv., March 4, 1913.

See Fr. Pat. 466,518 of 1913; preceding.—T. F. B.

Concrete; Manufacture of ——. R. Houben, Brussels. Eng. Pat. 4349, Feb. 19, 1914. Under Int. Conv., Nov. 19, 1913.

See Fr. Pat. 466,878 of 1914; preceding.—T. F. B.

Volcanic and other fusible rock; Manufacture of industrial objects from ——. F. Ribbe, Mauriac, France. U.S. Pat. 1,108,007, Aug. 18, 1914. Date of appl., July 13, 1911.

See Fr. Pat. 418,624 of 1910; this J., 1911, 88.—T. F. B.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast-iron pipe; External corrosion of ——. M. R. Pugh. Proc. Amer. Soc. Civil Eng., 1914, 40, 1641—1691.

Examples are given from France, England and the United States of the great durability of cast-iron piping and also of piping which deteriorated rapidly in 7—20 years, when laid in saline soils or in sea-water. The causes conducing to and inhibiting corrosion are discussed, and details of typical cases of corrosion are given with photographs and analyses. The remedies recommended are: increasing the natural resistance of the skin of the cast-iron, surrounding the piping with lime or cement, laying the piping in open trench or above ground, and galvanising the pipes. —J. H. J.

Iron and steel; Determination of carbon in —— by direct combustion in oxygen. J. R. Cain and H. E. Cleaves. J. Wash. Acad. Sci., 1914, **4**, 393—397. (See also this J., 1914, 696.)

To oxidise carbides of chromium, titanium or tungsten, in determining carbon by direct combustion, the tube should be heated at 1500° C. for 30 mins. after the metal has ceased to burn; slightly higher results are obtained in some cases than by the usual method.—W. R. S.

Steel; Titanium nitride in ——. G. F. Comstock. Met. and Chem. Eng., 1914, **12**, 577—580.

VARIOUS titanium compounds were incorporated with iron and steel in the presence or absence of alumina. The minute, hard, pink, non-metallic spots or inclusions, visible (under a magnification of at least 200 diameters) in rail steel which has been treated with ferro-carbon-titanium, appear to consist mainly, if not entirely, of titanium nitride; alumina is not necessary for their formation. —W. F. F. P.

Copper; The effects of repeated re-melting on ——. F. O. Clements. Amer. Inst. of Metals, Chicago, Sept. 7—11, 1914. [Advance proof.]

100 lb. of copper was melted and cast 4 times in succession under foundry conditions, and after the fourth casting, 16 lb. of the metal was melted with 2 oz. of boron suboxide and again cast. Samples from each casting were tested in a modified form of the Upton and Lewis machine, in which alternate bends were produced in a test-piece 1 in. wide and of a given thickness, and a graphic record made of the number of bends required, and the resistance offered, before fracture. The results obtained, together with those given by a sample of boronised copper melted and cast *in vacuo*, were :—

	Temperature of melting or casting ° C.		Average number of alternate bends.	Resistance offered to bend.	Percentage diminution in resistance, in 10-in. lengths measured on the machine diagram.
	Melting.	Casting.			
					%
Original metal	—	—	1515	100 (assumed)	2·7
After 1st heat	—	1120	850	97	5·5
After 2nd heat	—	1120	845	96	4·9
After 3rd heat	1165	—	762	96	8·5
After 4th heat	—	1115	334	96	22·6
After treatment with boron suboxide	1260	1149	2007	103	2·7
Boronised copper melted and cast *in vacuo*	—	—	3044	117·5	0·74

—W. E. F. P.

Silver and base metal in precious metal bullion; Determination of ——. F. P. Dewey. J. Ind. Eng. Chem., 1914, **6**, 650—658, 728—736.

THE results of a large number of bullion assays, some from the regular working of the Mint service of the U.S. Treasury, and some from special experiments, are tabulated and discussed. There are no effective means of controlling the two chief sources of error in the determination of base metals by cupellation, viz., absorption of gold and silver by the cupel and retention of base metal by the precious metals, and proof corrections may be fallacious, as the proofs are subject to the same uncontrollable errors. Recently a method for the direct determination of silver by fusing the bullion with cadmium in presence of potassium cyanide, dissolving the button in nitric acid, and titrating with ammonium thiocyanate (compare Whitehead, this J., 1892, 458), has been extensively tried in the U.S. Mint service, and, on the whole, the results compared favourably with those obtained by cupellation.—A. S.

[Copper.] Arsine (AsH_3) formation in electrolytic refining. F. R. Pyne. Eng. and Min. J., 1914, **98**, 432.

IN the electrolytic refining of copper, undesirable concentration of arsenious acid in the electrolyte is prevented by periodically electrolysing a portion of the latter with insoluble (lead) anodes and returning the purified solution to the bulk. Arsenious acid is reduced by nascent hydrogen, and, in the absence of sufficient copper in solution to form an insoluble arsenide, the AsH_3 produced is evolved. —W. E. F. P.

Copper; The crystalline structure of ——. W. L. Bragg. Phil. Mag., 1914, **28**, 355—360.

A NATURAL crystal of copper was examined by means of the X-ray spectrometer (Proc. Roy. Soc., 1913, **A88**, 428; 1914, **A89**, 468). The copper atoms are arranged on a face-centred cubic "lattice," the crystal structure being the simplest of any yet analysed.—F. SODDY.

Brass; Use of producer gas for melting yellow ——. E. B. Guenther. Amer. Inst. Metals, Sept. 7—11, 1914. [Advance proof.]

FOUR producer-gas furnaces with separate preheaters were tested against four ordinary coke furnaces. The chief advantages found with producer-gas furnaces were: cleanliness, easy control and evenness of temperature, with consequent saving in repairs to furnace linings and in crucibles, less loss by oxidation, and greater ease in recovering spilt metal. Detailed calculations showed a considerable saving in cost.—O. E. M.

Brass-melting furnaces; Tests of natural-gas fired ——. F. L. Wolf and R. B. Burr. Amer. Inst. Metals, Sept. 7—11, 1914. [Advance proof.]

THREE types of non-tilting crucible furnace were tested under factory conditions. The first, with chamber burner and air preheater, was efficient with high pressures an continual repair of the burner, but its radiation losse and injurious gas leakage were high. The second, wit air-preheater and rising body to give access to the crucibl was efficient with 2 lb. pressure of air, but this was offse by the cost of repairs, mechanical defects, and difficult of manipulation. The third, a converted pit furnac when large enough to take a thick lining, and equipp with preheating coils, and a simple tube burner, whic allowed the use of low pressures of gas and air, was a efficient as the more complicated types, cost little fc maintenance and was convenient to work.—O. E. M.

Brass furnaces; Melting losses in electric ——. H. W. Gillett and J. M. Lohr. Amer. Inst. of Metals, Sept. 7—11, 1914. [Advance proof.]

Various kinds of closed electric furnaces, in which local overheating is avoided, such as the resister and crucible type, gave very low metal losses and a decided advantage over furnaces fired with fuel. Electric arc furnaces showed greater losses, due apparently to the high temperature of the arc producing local overheating. To prevent oxidation a reducing atmosphere should be maintained, and with resistance furnaces this may be secured by dropping oil into the furnace. Tilting furnaces gave greater metal losses, due to greater exposure of the metal and volatilisation of the zinc during pouring.—B. N.

Pyrometers for molten brass and bronze. H. W. Gillett. Amer. Inst. of Metals, Sept. 7—11, 1914. [Advance proof.]

A preliminary report of an investigation, by the U.S. Bureau of Mines, to discover or devise a pyrometer suitable for general use in brass foundries. On account of zinc fume, pyrometers of the ordinary radiation and optical types were generally unsatisfactory, or at best of very limited application. By employing a closed-end tube with the former type, the time lag was too high owing to the size of tube required. Satisfactory results for large-scale laboratory work were obtained with the optical type when a sighting tube was used, but the practical utility of this type under general foundry conditions is doubtful. All forms of thermo-couples in which the elements (base metals) were wholly or partly in contact with the molten charge were unsatisfactory, mainly on account of rapid corrosion. A form of protected platinum platinum-rhodium couple was devised in which the wires were insulated at the lower part by Marquardt mass (a porcelain-like material containing SiO_2 35—30 and Al_2O_3 60—65%), and at the upper part by fireclay, tubing, and placed in a sectional nickel tube, 4 ft. long, closed at the lower end by a small molybdenum cap or tip and filled with anhydrous, powdered alumina after the couple was in position. The lower 10 in. of the nickel tube was protected by a loosely-fitting sleeve of "silfrax" (a dense, metal-like form of carborundum) having at the bottom an opening through which the molybdenum tip projected for ⅝ in. This instrument proved very efficient up to 1330° C. under foundry conditions, the time lag being small and apparently decreasing with increasing temperature.—W. E. F. P.

Lead smelting; Use of the bag-house in ——. L. D. Anderson. Min. and Eng. World, 1914, **41**, 239—242.

At the Midvale (Utah) smelter, all the gases from the 6 blast-furnaces, roasting-furnaces, and converters for blast-roasting are filtered in a bag-house. By cutting off the blast and applying a slight suction, the dust is detached and drops through hoppers into wagons. The roaster dust containing 9—16% As is briquetted with fine ore and smelted. The dust from the blast-furnace, which contains 35—45% As, is used for the manufacture of white arsenic; it is very inflammable, especially when containing more than 45% As. When an efficient bag-house is used, most of the loss of lead in lead smelting can be traced directly to the slag.—W. R. S.

Lead matte converting at Tooele (Utah). O. M. Kuchs. Amer. Inst. Min. Eng., Aug. 1914. Eng. and Min. J., 1914, **98**, 379—380.

Lead-copper matte is "converted" in basic-lined vessels without addition of silicious fluxes, the blowing being continued until the lead is practically eliminated. The lead fume is recovered in a bag-house, and contains sufficient zinc oxide to prevent injury to the bags by acid gases; the residual copper product and the highly ferruginous "slag" are treated in ordinary "copper" converters. The percentage compositions of the matte, slag and fume are:—

	Pb.	Cu.	Ag. (oz. per ton.)	SiO_2.	Fe.	S.	Zn
Matte	15·0	9·05	20·3	—	37·0	23·0	5·4
Slag	1·4	—	—	1·7	59·1	1·8	4·0
Fume	64·2	0·37	5·7	0·2	0·4	6·0	10·4

—W. E. F. P.

Tin-wolfram (tungsten) bismuth ores; Treatment of ——. L. Hills. Min. and Eng. Review, July 16, 1914. Eng. and Min. J., 1914, **98**, 486.

Magnetic separation of a concentrate containing Sn 40%, WO_3 22, and Bi 6%, yielded a magnetite concentrate, and a pyrite concentrate, both together containing less than 1% of the three valuable metals; a product assaying WO_3 70%, Sn 0·7%; and a residue: Sn 56·3%, Bi 8%, and WO_3 0·7%.

Die-casting practice; Modern ——. C. Pack. Amer. Inst. Metals, Chicago, Sept. 7—11, 1914. [Advance proof.] (See also this J., 1914, 203.)

The alloys used contain Zn 70—90%, with Sn, Cu, Al, Sb and Pb; Sn 60% (or over), with Pb, Sb, Cu and Zn; and Pb 60% (or over), with Sn and Sb. Aluminium alloys may also be used. A typical zinc alloy contains Zn 84·5, Sn 9·0, Cu 4·5, and Al 2·0%, and has a tensile strength of over 18,000 lb. per sq. in. The castings are extensively used in the motor car industry and may be protected from corrosion by water and by impurities in gasoline, by plating with copper or nickel. The machines used in casting are of two types. In the air machines the metal is usually forced upwards from the closed melting pot into the die by opening a compressed-air valve. Plunger machines are more generally used, in which a horizontal cylinder is immersed in the molten metal and is connected through a nozzle with the die. The metal is forced into the die by a plunger in the cylinder, operated by a lever, and a cutting device is forced through the gate of the die by a second lever. 230 castings can be made per hour, and they are accurate within 0·005 in., or for castings not exceeding 1 in. either way, within 0·0005 in.—A. T. L.

Zinc in alloys; Determination of ——. G. E. F. Lundell and N. K. Bee. Amer. Inst. Metals, Sept. 7—11, 1914. [Advance proof.]

The solution of the alloy, freed from Hg′, Cu, Bi, Cd, As‴, Mn, K_2SO_4, $NH_4C_2H_3O_2$, NH_4CNS, H_2S, oxides of N, and any large quantity of Ni, and containing not more than 10% of acid, is precipitated with a solution containing 39 grms. of KCNS and 27 grms. of $HgCl_2$ per litre. The precipitate, $ZnHg(CNS)_4,H_2O$, is collected on a Gooch filter, dried at 100°—108° C., and weighed, or is dissolved in very dilute nitric acid containing iron alum, and determined volumetrically by Volhard's method. The results agreed with those obtained by the pyrosulphate method.—O. E. M.

Mercury ores; New wet process for the treatment of low-grade ——. G. Carrara. Rend. R. Istit. Lombardo Sci. e Let., 1914, **47**, 117. Annali Chim. Appl., 1914, **2**, 52.

The pulverised ore is concentrated to ⅕—¼ of its weight by levigation, and treated with a solution of sodium hypochlorite obtained by electrolysis of sodium chloride. Mercuric sulphide is oxidised to sulphate and this is converted into chloride by the excess of sodium chloride present. Mercury is precipitated from the solution with sodium sulphide, and after removal of the precipitate, the liquid, which should be free from any excess of sodium sulphide, is electrolysed to obtain sodium hypochlorite for use again.—A. S.

Cobalt; Some recent applications of metallic ——. de C. Browne. Amer. Inst. of Metals, Chicago, Sept. 7—11, 1914. [Advance proof.]

The percentage elongation and reduction of area of manganese bronze and the alloy, Cu 88, Sn 10, Zn 2%, were greatly increased by the addition of 0·5% Co; the tensile strength and elastic limit were considerably reduced in the former, but not seriously affected in the latter case. The tensile strength of "low brass" (Cu 80, Zn 20%) was increased 15 and 20% by the addition of 0·25 and 0·5% Co, respectively. The cobalt was added in the form of an alloy containing Co 10 and Cu 90%. —W. E. F. P.

Eutectics; Growth of metallic ——. F. E. E. Lamplough and J. T. Scott. Roy. Soc. Proc., 1914, A **90**, 600—604.

The formation, around the primary crystals of an alloy, of a halo or envelope of the second constituent, separating the primary crystals from the banded eutectic, has been attributed to undercooling at the first moment of solidification of the eutectic, whilst Desch has suggested that the phenomenon may be due to segregation of the eutectic around the primary crystals during solidification. Temperature-time curves of alloys cooling under different conditions were taken, and the solid alloys were examined micrographically. In some cases considerable undercooling existed without the formation of halos and in others marked halos were accompanied by only slight undercooling. The formation of the halo was not affected when undercooling at the moment of eutectic formation was prevented by inoculation or by shaking. In the case of Cd-Sn alloys the halo was observed only when the primary crystals had become enveloped by the growing eutectic. It was found possible to divide the greater number of eutectics into two classes. Halos were observed only in the case of eutectics of the first class, characterised by spherical radiating growth. Examples are Sn-Pb, Sn-Cd, Zn-Cd, Ag-Cu, Zn-Al and Cu-Cu_3P eutectics. Eutectics of the second class had well-defined crystal contours, showing in section a herring-bone structure. Examples are Bi-Pb, Bi-Sn, Ag_3Sb-Sb, Au-$AuSb_2$, Mg_2Pb-Mg, Mg_2Sn-Mg, ZnSb-Sb, $NaCd_6$-Cd, and $NaSn_2$-Sn eutectics. Some eutectics, *e.g.* Bi-Cd, Cu_2Sb-Sb, and SnAu-Sn, belonged to a third type, of irregular form: in these one constituent crystallised as laminæ and the eutectic growth originated at one of the primaries.—A. S.

Patents.

Iron; Local hardening of —— and malleable iron castings. Vickers Ltd., Sheffield, and C. L. Sumpter, Grindleford Bridge, Derbyshire. Eng. Pat. 18,643, Aug. 16, 1913.

The part of the casting to be treated, is either protected from decarburisation by a coating of "paint," etc., during annealing, or is re-carburised and then heated by means of an intensely hot flame (*e.g.*, oxy-acetylene) while the casting is just covered with water by immersion or otherwise.—W. E. F. P.

[*Iron and steel.*] *Case-hardening process.* A. W. Machlet, Elizabeth, N.J. U.S. Pat. 1,106,573, Aug. 11, 1914; date of appl., Dec. 19. 1911.

The articles are placed in a heat-retaining oven and heated to carburising temperature by the direct action of flames. The flames are then extinguished and a suitable gas introduced into the oven to effect carburisation while the metal is slowly cooling. These operations may be repeated. —A. S.

[*Open-hearth steel*] *Furnace-wall construction.* N. E. Maccallum, Phoenixville, Pa. U.S. Pat. 1,106,725, Aug. 11, 1914; date of appl., May 13, 1913.

The walls of the combustion chamber of an open-hearth steel furnace are composed of a number of iron containers filled with basic material or a mixture of basic and neutral materials.—W. H. C.

[*Iron and steel.*] *Soldering; Process of mixed —— and products obtained thereby.* E. L. Chameroy fils. Fr. Pat. 468,454, Feb. 14, 1914.

Steel, malleable cast iron, or the like is soldered to cast iron by keeping the surfaces in contact at such a temperature that the surface layer of the cast iron yields a portion of its carbon to the surface layer of the other metal, forming an intermediate layer which acts as a solder. The piece of steel or the like may be heated and immersed in the molten cast-iron, or the two metals, in contact, may be heated by an oxy-hydrogen or oxy-acetylene flame. The process is suitable for the production of pistons, tyres, valves, etc., with a core of steel or malleable cast iron and an outer layer of cast iron, of cast-iron cog wheels with steel teeth, paddle-wheels with steel blades, and the like. —A. S.

Tool steel; Manufacture of extra rapid ——. E. Jaboulay. Fr. Pat. 468,796, Feb. 16, 1914.

From 15 to 30% Cr is added to steel, which may also be alloyed with small quantities of other metals (W, Mo, V). Tool steel made in this way and containing, for example: Fe 60·0, Cr 21·0, W 8·5, Mo 8·5, V 0·5, C 1·5%, may be used at nearly double the speed attainable with the special steels hitherto known.—A. S.

Iron alloys; Process of manufacturing ——. G. M. Colvocoresses, New York. U.S. Pats. (a) 1,106,785 and (b) 1,106,786, Aug. 11, 1914; dates of appl., June 12 and 19, 1913.

(a) A sulphide ore containing Ni 0·5—12, Cu 0·2—10, and Fe 25—60%, is crushed, roasted, and smelted with a flux so as to remove the non-metallic elements as silicates and produce a pig of Fe, Ni, Cu and C, which is refined to obtain a steel alloy. (b) A blast- or reverberatory furnace slag containing Fe 20—50, Ni 0·2—2, and Cu 0·1—2%, is smelted with fuel and flux, and the resulting pig is refined at a sufficiently high temperature to obtain a steel alloy containing Cu 0·2—2, Ni 0·4—4, and C up to 1%.—A. S.

Tin ores and slags containing tin; Treatment of ——. Billiton Maatschappij, The Hague, Holland. Eng. Pat. 18,422, Aug. 13, 1913. Under Int. Conv., Sept. 16, 1912.

A mixture of the material with iron pyrites is smelted to produce Sn-Fe matte, the slag obtained being re-smelted with pyrites as often as necessary. The matte is sintered with sodium sulphate and carbon to convert the tin into sulpho-stannate which is subsequently extracted with water.—W. E. F. P.

[*Metallic*] *Coatings or deposits; Process of and apparatu for applying —— to surfaces.* R. K. Morcom, London Eng. Pats. (a) 18,840 and (b) 18,841, Aug. 19, 1913.

(a) A rod of the metal to be deposited is subjected to th action of a powerful blast while heated below its meltin or oxidising point, and the resulting spray projected upo the required surface, which may be preheated or not. Th rod may be fed into a blowpipe flame, or form on electrode of an electric arc against which the blast i directed; and sprays of two or more separate metals ma be caused to impinge simultaneously upon the surface to b covered. (b) For spraying molten metal, etc., upon th interior surfaces of hollow bodies a flexible blowpipe employed, to the nozzle of which a deflecting surface spreader—convex towards the blast—is attached b means of wires. (See also this J., 1914, 925.)—W. E. F.

Ore concentration. G. A. Chapman, Miami, Ariz., U.S. Eng. Pat. 18,937, Aug. 20, 1913. Under Int. Conv May 8, 1913.

In an agitation-froth process, the partly crushed ore ground (*e.g.*, in a Hardinge mill) with water containi "a modifying agent" (cresol), the pulp mixed with frothing agent (turpentine), agitated, and separated usual; the maximum amounts of modifying agent ar frothing agent employed are respectively 0·1 and 0·4 of the weight of ore.—W. E. F. P.

Ore concentrator. J. Weatherby, New Cumberland, P U.S.A. Eng. Pat. 19,302, Aug. 26, 1913. Under I Conv., Jan. 4, 1913.

A shaking-table has riffles of magnetic material dispos within a magnetic field, so that, by contact with the rif edges, slightly paramagnetic ore particles are carried across the channels by the water and thus separated. —W. E. F. P.

Ores; Concentration of ——. Minerals Separation, Ltd. Fr. Pat. 468,136, Feb. 6, 1914.

The process is intended particularly for the treatment of very finely divided ores containing galena and blende, *e.g.*, the slimes produced in crushing Broken Hill ores. The pulp, mixed with a small quantity of a frothing agent, such as eucalyptus oil, is passed into a separator, into which air or other gas is delivered at the bottom. The mixture is vigorously agitated, *e.g.*, by means of a centrifugal pump, in the lower part of the separator, and a relatively tranquil zone is maintained near the top. The first portions of the froth removed from the surface carry most of the galena and the subsequent portions most of the blende. A series of separators is preferably used, in which the different fractions are treated successively. Modifications of the process are also described in which the pulp is treated by agitation and aeration, without acid, but with addition of 0·003% of eucalyptus oil; or the pulp is mixed with a small quantity of oil, without acid, and treated first with a limited quantity of air to float certain constituents and then with a further quantity of oil and a larger volume of air, and also, if necessary, with acid; or the pulp is mixed with an acid, and certain constituents removed by flotation without the use of a frothing agent, the residue being treated by agitation and aeration in presence of a frothing agent to effect selective flotation of other constituents.—A. S.

Ores; Process and apparatus for concentrating —— *by flotation.* J. M. Ormaza. Fr. Pat. 468,395, Feb. 13, 1914.

The ore is crushed in a ball-mill to about 1 mm. size, passed through an inclined, rotary drying chamber, and then to a hopper whence it is delivered between a pair of adjustable rollers on to an inclined table, to which a vibratory motion is imparted. From the table the material flows uniformly into a second hopper from which it falls between another pair of adjustable rollers on to a mass of water carrying an upper stratum of oil and moving at right angles to the path of the ore. A regulated blast of air is directed across the surface of the water at the place where it receives the ore. The particles which float overflow with the water into an adjacent tank, whilst the remainder of the ore sinks, and is discharged as pulp on to a Wilfley table, the inclination of which can be varied. The different sections of the plant are arranged so that the movement of the ore is effected as far as possible by gravity; and it is possible to treat 24 tons of ore per day of 10 hours with an expenditure of 15 horse-power.—A. S.

Tungsten and the like metals; Manufacture of drawn wires from ——. C. Gladitz, London. Eng. Pat. 20,122, Sept. 5, 1913.

The cross-section is reduced by cold drawing by a considerable amount in relatively few stages so as to produce an amorphous structure, and the wire is then heated in an inert atmosphere to effect recrystallisation of the metal. —W. E. F. P.

Cuprous chloride; Process of reducing ——. F. Laist, Anaconda, Mont. U.S. Pat. 1,104,907, July 28, 1914; dato of appl., April 30, 1914.

Cuprous chloride precipitated from chloride leaching solutions is fused with carbonacous matter and an alkaline-earth carbonate, to form copper, and an alkaline-earth chloride, which can be used in subsequent leaching operation.—O. R.

Copper: Process for extracting fractions rich in —— *from cupriferous ores and gangues.* "Azurit" Vegyi Ipar Részvenytársaság. Fr. Pat. 468,839, Feb. 23, 1914. Under Int. Conv., Feb. 27, 1913.

Low-grade copper ores are roasted, if necessary, then finely ground, and treated with a solution of aluminium sulphate or alum, which has a selective action on the copper oxide or basic carbonate present, copper sulphate and aluminium hydroxide being formed. On standing, insoluble basic double compounds of aluminium and copper are formed, and these are converted into aluminium and copper sulphates by treatment with sulphuric acid. The ore may be treated in a filtering chamber with aluminium sulphate, and after this has drained off, the residue treated with sulphuric acid. The two filtrates are mixed and again poured on the residue, which is afterwards treated with a further quantity of sulphuric acid, and these operations repeated until the copper is completely extracted. Ores in which the gangue is composed of felspar or the like, yielding aluminium sulphate on roasting, may be treated with water instead of with a solution of aluminium sulphate. From the final solution containing aluminium and copper sulphates, part of the copper sulphate is recovered by crystallisation, and the mother-liquor, containing the double salt, $CuSO_4,7H_2O+Al_2(SO_4)_3,7H_2O$, is used again in the process.—A. S.

Zinc ores; Process and apparatus for the treatment of ——. J. J. Boguski and Soc. Minière et Industrielle Saturn. First Addition, dated Feb. 6, 1914, to Fr. Pat. 441,098, March 8, 1912 (this J., 1912, 823).

When the ammoniacal zinc solution obtained as described in the chief patent (*loc. cit.*) is heated under diminished pressure to recover the ammonia, the basic zinc carbonate precipitated tends to form a hard mass on the bottom of the receptacle. According to the present patent the ammoniacal zinc solution is added to a large quantity of boiling water or weak ammoniacal liquor and superheated steam is passed through the mixture, whereby the zinc is separated as a coarsely crystalline precipitate consisting mainly of hydroxide.—A. S.

Metal [*zinc*] *vapours; Process for the recovery of* ——. Helfenstein-Elektro-Ofen-Ges. m. b. H. Fr. Pat. 468,445, Feb. 14, 1914. Under Int. Conv., Feb. 18, 1913.

In smelting zinc ores in an electric furnace, the gases and vapours evolved before the distillation of the zinc commences are drawn off separately through the upper portion of the charge, oxidation of the zinc vapour evolved later being thus reduced to a minimum and the zinc largely condensed in the liquid form. Any zinc vapour drawn off with the gases is condensed in the cooler, upper portion of the charge and carried down therewith into the reduction chamber.—A. S.

Vanadium; Extraction of —— *from ores.* H. Boericke, Vanadium, Colo. U.S. Pats. (A) 1,105,244 and (B) 1,105,245, July 28, 1914; dates of appl., Mar. 27, 1912, and Jan. 20, 1914.

The vanadium is converted into sodium vanadate by heating the ore with sodium chloride and (A) a metallic sulphate, such as iron sulphate, or (B) sulphur, or a non-metallic compound of sulphur.—W. R. S.

Alloy of vanadium and precious metals. Vanadium-gold alloy. F. von Oefele, Assignor to H. Schweitzer, New York. U.S. Pats. (A) 1,107,180 and (B) 1,107,181, Aug. 11, 1914; dates of appl., Oct. 11, 1911 and Oct. 22, 1912.

An alloy of (A) gold-vanadium with other metals, (B) vanadium and gold.—A. S.

Lead; Apparatus for refining and desilverising ——. W. Thum, Hammond, Ind. U.S. Pat. 1,106,480, Aug. 11, 1914; date of appl., Dec. 9, 1910.

A melting "kettle" is connected with a series of crystallising "kettles," into which the molten metal is passed successively, being forced from one "kettle" to another by means of a fluid under pressure. At the bottom of the melting "kettle," on opposite sides, are two spouts and the portion of the "setting" over the spouts is composed of removable blocks of refractory material, retained in position by sheet steel sections on their outer sides; the steel sections slide in passages connected with the fixed main portion of the setting to allow of removal of the blocks.—A. S.

Soldering alloy. G. D. Long and E. W. Rapp, Granite City, Ill. U.S. Pat. 1,107,082, Aug. 11, 1914; date of appl., May 15, 1914.

An alloy of Al 400, Zn 400, Sn 700, Bi 8, Cu 8, Sb 28, and Hg not over 2 parts.—A. S.

Aluminium alloy. W. A. McAdams. Fr. Pat. 468,853, Feb. 24, 1914.

See U.S. Pat. 1,104,369 of 1914; this J., 1914, 869. Silver is used in relatively small quantities (up to 20%), and small proportions of copper, zinc, or titanium may also be added.—T. F. B.

Ores; Process of treating ——. N. C. Christensen, jun., and T. P. Holt; Christensen assignor to G. H. Dern, Salt Lake City, Utah. U.S. Pat. 1,107,240, Aug. 11, 1914; date of appl., Aug. 3, 1911.

The finely-divided ore is intimately mixed with 2—6% of finely-divided fuel, and, if desired, also with suitable chemicals, the fuel is ignited and the mixture is roasted by the heat developed by the combustion of the fuel with an air-blast, which is regulated so that the temperature attained is insufficient to fuse or sinter the ore. The useful metals are extracted from the residue by leaching with a solvent.—A. S.

Furnace for the heat treatment of metals. A. Grebel. Fr. Pat. 468,234, April 19, 1913.

The furnace is heated by means of producer gas enriched with the vapour of heavy hydrocarbons, an open vessel in which a constant level of petroleum or coal tar oil is maintained, being disposed in the conduit leading from the gas producer to the burners. The openings through which the heating gas and the preheated air from the recuperator enter the working chamber, and those through which the waste gases leave, are so arranged and regulated that a more intense combustion is attained near the door or doors of the working chamber, in order to compensate for cooling and influx of cold air.—A. S.

Furnace; Semi-continuous —— fired with coke or coal, for reheating, annealing, cementation, or tempering. J. Conor. Fr. Pat. 468,621, April 28, 1913.

Suitable connections are provided so that when the door of the working chamber is opened, a damper in the flue leading from the fire-box to the chimney is automatically closed, thus preventing influx of cold air into the working chamber. In like manner when the door of the fire-box is opened, a damper automatically closes communication between the fire-box and the working chamber and another closes the air-supply pipe.—A. S.

Furnace for roasting ores. A. Zavelberg. Fr. Pat. 468,685, Feb. 3, 1914.

The ore is moved over each of the superposed hearths by rabble-arms carried on supports which travel on a circular track either around the outside of a cylindrical furnace or around the inner periphery of an annular furnace. The openings through which the arms project into the furnace are closed by means of a sand seal fixed to the furnace and plates carried by the arms. The arches above the roasting hearths are provided with angle-irons which bear on rollers or the like carried by the supports for the rabble-arms.—A. S.

Roasting furnace; Mechanical ——. J. Claude. Fr. Pat. 468,968, May 7, 1913.

The furnace comprises a number of superposed cylindrical chambers for the charge, and a central vertical rotating shaft carrying radial rabble-arms. Special features claimed are the method of mounting the vertical shaft in its bearings and of fixing the arms to the shaft, the shape of the teeth carried by the arms, and the arrangement of passages within the shaft and arms for cooling air which is afterwards admitted to the combustion chambers or to the furnace chambers.—A. T. L.

Plated ware; Process of obtaining adherent deposits of precious metals on alloys usually regarded as unsuitable for the manufacture of ——. Maison Murat. Fr. Pat. 468,801, May 2, 1913.

The alloy is coated electrolytically with Cu, Ni, Co, Ag, or the like, and then plated with Au, Ag, or other precious metal foil by the known process of heating and strongly compressing. By this method alloys containing relatively high proportions of Zn or Al, which cannot be plated directly by the hot method, may be used.—A. S.

Iron; Process of treating cast ——. J. E. Johnson, jun., New York. Eng. Pat. 24,297, Oct. 27, 1913. Under Int. Conv., Aug. 13, 1913.

See Fr. Pat. 464,208 of 1913; this J., 1914, 488.—T. F. B.

Solder; Impts. in and process of making soft ——. J. T. Dwyer, St. Louis, U.S.A. Eng. Pat. 118, Jan. 2, 1914. Under Int. Conv., Jan. 2, 1913.

See U.S. Pat. 1,059,982 of 1913; this J., 1913, 608.—T.F.B.

Roasting-furnace. A. Zavelberg, Hohenlohehütte, Germany. U.S. Pat. 1,107,006, Aug. 11, 1914. Date of appl., May 14, 1914.

See Fr. Pat. 468,685 of 1914; preceding.—T. F. B.

Copper; Process for welding ——. H. Suzuki, Shibaku, Japan. U.S. Pat. 1,107,865, Aug. 18, 1914. Date of appl., Aug. 2, 1913.

See Fr. Pat. 461,688 of 1913; this J., 1914, 205.—T. F. B.

Zinc-blende and other metalliferous constituents; Separation of —— from ore concentrates and slimes by flotation or granulation. E. J. Horwood, Broken Hill, N.S.W. U.S. Pat. 1,108,440, Aug. 25, 1914. Date of appl., Dec. 4, 1913.

See Eng. Pat. 28,604 of 1913; this J., 1914, 793.—T. F. B.

Annealing or cementing various articles; Method and apparatus for ——. G. Richter, Assignor to Stettiner Chamotte-Fabrik A.-G. vorm. Didier, Stettin, Germany. U.S. Pat. 1,109,362, Sept. 1, 1914. Date of appl., May 29, 1913.

See Ger. Pat. 265,761 of 1913; this J., 1913, 1161.—T.F.B.

Furnace for treating molten metals; Single or multiphase electric [induction] ——. P. Lescure. Fr. Pat. 468,139, Feb. 6, 1914. Under Int. Conv., Feb. 7, 1913.

See Eng. Pat. 3291 of 1914; this J., 1914, 794.—B. N.

Process of and apparatus for thickening and agitating pulp. Eng. Pat. 22,411. *See* I.

Titanic oxide concentrate and method for producing the same. Method for concentrating titanic oxide from substances containing it and iron oxide. Method of obtaining titanic oxide. U.S. Pats. 1,106,406—1,106,410. *See* VII.

Treatment of slag for the manufacture of bricks. Eng. Pats. 18,806 and 7027. *See* IX.

XI.—ELECTRO-CHEMISTRY.

Aluminium cathode; Disintegration of the ——. L. L. Campbell. Phil. Mag., 1914. **28**, 347—354.

The aluminium cathode, hitherto supposed to disintegrate, to an appreciable extent, only in the monatomic gases, was found to "splutter" violently in presence of the halogens and some other gases or in the vapour of mercury or cadmium. Disintegration seemed to take place best when the pressure in the tube was at the ordinary X-ray stage and the cathode dark-space had reached the walls of the tube next the cathode, the rate of disintegration increasing, in general, with the molecular weight of the discharge gas.—F. Sodn.

Electrolysis of fused borates. Zschille-Hartmann. *See* VII.

Patents

Ozone; Apparatus for producing ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 21,779, Sept. 26, 1913.

The units of the ozoniser are connected with a source of direct current through an inductive device (transformer), in the primary circuit of which is an electro-magnetic current interruptor. The electro-magnet is provided with a number of coils, each having a different number of turns, and by including one or other of these coils in the circuit, the reactance and hence the rate of ozone production may be varied. In order to keep constant the "ampere turns" of the electro-magnet, and thus minimise the noise produced by a change in the number of "turns," means are provided for including either all or only a part of the coils of the primary of the transformer in the circuit.—A. S.

Electrode for furnaces. C. Hering, Philadelphia, Pa. U.S. Pat. 1,106,381, Aug. 11, 1914; date of appl., Dec. 12, 1912.

The electrode is composed of a shell or cage of conducting material, diminishing in periphery and increasing in thickness from its outer towards its inner end, and arranged so that the conducting paths converge and unite. The current flows to or from a mass of conducting fluid in the furnace through the electrode, passing through the union of the conducting paths.—B. N.

Furnace; Electric [induction] ——. G. H. Benjamin, New York. U.S. Pat. 1,106,486, Aug. 11, 1914; date of appl., Dec. 19, 1913.

The furnace comprises a closed metallic core, a fixed primary, and a movable secondary, in the form of an annular crucible with a body of metal therein. The crucible is provided with ribs in the bottom projecting upwards, together with means for rotating the secondary relative to the core and primary. Material is introduced into the crucible through a sectional cover, and means are provided for exhausting gases from the crucible.—B. N.

Electrolytic apparatus. I. H. Levin. Fr. Pat. 467,945, Jan. 31, 1914. Under Int. Conv., May 9, 1913.

Each element comprises an anode and a cathode, with an interposed diaphragm, built up in the form of a filter-press. Means are provided for regulating the hydrostatic pressure on the two faces of the diaphragm, and for maintaining an equal pressure from one end of the apparatus to the other. A reservoir, consisting of two separate chambers with independent non-communicating conduits, is employed to supply electrolyte from the chambers to the neighbourhood of the anode and cathode respectively. The chambers are surmounted by bells, and the disengaged gases are brought to these by means of conduits communicating with the opposite faces of the diaphragms, means being also provided for equalising the pressures of gas and liquid in the reservoir chambers.—B. N.

Ultra-violet rays; Industrial production of —— by means of [electric] sparks. J. de Kowalski-Wierusz. Fr. Pat. 468,215, Feb. 5, 1914. Under Int. Conv., April 15, 1913.

Electrodes of nickel, tungsten, or their alloys, either alone or in combination with rare earths, are employed, so that the sparks are greatly weakened, and by an appropriate choice of electric constants, employing a wave length of less than 3000 m., a great amplitude of current intensity is obtained. The ultra-violet rays, produced by the sparks, may be used for sterilising liquids, and the yield is increased by using different materials for the two electrodes and plunging them into the liquid to be treated. For the production of chemical reactions, where the gases formed by the sparks would be objectionable, a screen, such as quartz, may be interposed between the sparks and the material under treatment.—B. N.

Electro-chemical treatment of liquids [e.g. water]; Process and apparatus for the ——. C. P. Landreth. Fr. Pats. (a) 468,242, Feb. 9, 1914, and (b) 468,277, Feb. 10, 1914. Under Int. Conv., Feb. 21, 1913.

(a) A portion of the liquid to be treated [*e.g. water*] is diverted under pressure into a treating chamber, wherein it is mixed with excess of a soluble salt, and subjected to the action of an electric current, the anode being constructed of a metal, such as aluminium, which is attacked with the formation of hydroxide. The treated liquid is then mixed with the mass of untreated liquid, and the aluminium hydroxide serves as a precipitant for removing impurities. The electrodes are arranged in groups, so that one group may be removed independently of the others, and instead of a direct current, both direct and alternating currents may be used simultaneously. Rotating elements, working between the electrodes, are employed for agitating the liquid and giving it a movement independent of that of its flow, thus clearing the electrodes of deposits. (b) A positive metallic electrode, for example of iron, is employed, and a soluble hydroxide is added to the liquid under treatment, thus producing under the influence of the electric current an increase of hydroxyl ions, any organic material in the liquid being thus oxidised. The process may also be employed for the treatment of liquids containing soluble encrusting salts, or colloidal impurity, or both, by adding to the liquid, after the passage of the current through it, a reagent producing insoluble salts or a coagulant for the removal of the colloid. The apparatus comprises an electrolytic vessel containing positive and negative electrodes immersed in the portion of the electrolyte to be treated, the treated portion being afterwards mixed with the untreated mass of the liquid. The current may be interrupted after a time, and the whole of the electrodes may be connected, exterior to the electrolyte, with an electro-positive mass within the electrolyte which is normally out of the circuit, so that both positive and negative electrodes then become electro-negative with respect to the mass.—B. N.

Accumulator electrodes; Process for producing highly porous ——. Gebr. Stanislaw und Georgij Gaszynski, Apoznanski und Co. Ger. Pat. 275,881, Dec. 3, 1910.

The plates to which the paste has been applied are dried at high temperatures in closed receptacles which are not affected by acids. The rapid evolution of gas makes the paste porous, and the pressure generated hardens the mass.—T. F. B.

Oxygen compounds of nickel; Process for manufacturing a mass of higher —— for use in the positive electrodes of alkaline accumulators. Svenska Ackumulator Aktiebolaget Jungner, Stockholm. Eng. Pat. 1062, Jan. 14, 1914. Under Int. Conv., Jan. 16, 1913.

See Fr. Pat. 467,311 of 1914; this J., 1914, 871.—T. F. B.

Electro-optical cell. C. Stille, Zehlendorf-West, Germany. U.S. Pat. 1,108,638, Aug. 25, 1914. Date of appl., April 22, 1913.

See Eng. Pat. 9060 of 1913; this J., 1913, 873.—T. F. B.

Electric arc furnaces; Stabilising means for ——. C. E. Guye, Geneva, Switzerland, Assignor to Southern Power Co., Charlotte, N.C. U.S. Pat. 1,109,350, Sept. 1, 1914. Date of appl., Jan. 8, 1912.

See Fr. Pat. 438,783 of 1912; this J., 1912, 649.—T. F. B.

Process of producing acetic acid. U.S. Pat. 1,104,978. *See* VII.

XII.—FATS ; OILS ; WAXES.

Oil-producing plants and fats. Voigt. Jahresber. Inst. angew. Bot. in Hamburg. Chem. Rev. Fett-Ind., 1914, **21**, 117—119.

For many years large quantities of the kernels of mowrah or illipé nuts (from *Illipe latifolia*) have been imported into Hamburg, and recently the fat from them has been used for edible purposes. All attempts to use the residual oil-cake as a feeding stuff have been unsuccessful owing to the large proportion of a saponin with pronounced hæmolytic action. More recently the kernels of *I. longifolia* and *I. malabarica* and of *Shorea stenoptera* have also been imported under the name of "Illipé nuts." Other imported oil seeds include habock beans probably from *Bassia Mottleyana* (Dutch Indies), candle nuts (British India and Java), kemiri nuts (Java), lumbang nuts (Philippines), hot-caylai (Cochin-China), and lama nuts (Samoa). Experiments have been made as to the suitability for food of the fats of the nuts of various species of *Canarium*, including *C. commune*, *C. polyphyllum* (New Guinea), *C. luzonicum* and *C. ovatum*, of pili nuts (Manila), and of *Herea* seeds (Malay). Of African seeds there have been occasional imports of manketti nuts, and the fruit of *Balanites Maughami* (Portuguese W. Africa), the utilisation of which appears unprofitable owing to the small proportion of oil and the difficulty of extracting it. American products included cohune nuts and the seeds of *Virola bicuhyba*, also the seeds of *Carapa guayensis*, and "andiroba paste" prepared therefrom in Brazil. *Manketti-oil-cake* contained : water 8·1, ash 2·5, proteins 5·8, fat 1·8, carbohydrates 48·1, and crude fibre 33·7%.—C. A. M.

Cohune nuts from British Honduras ; [Fats and oil-cake from ——]. Bull. Imp. Inst., 1914, **12**, 237—242.

Three samples of the outer fibrous layer of the fruit of the cohune palm (*Attalea cohune*) yielded 9·3 to 20·6% of a dark green fat, the colour of which could be largely removed by animal charcoal. Five samples of the kernels contained 65·4 to 71·6% of a white crystalline fat resembling coconut oil in appearance and odour. These fats had the following characters :—

	Fat from fruit.		Fat from kernels.				
	1	2	1	2	3	4	5
Specific gravity at 100°/15·5° C. ..	0·848	0·855	0·870	0·871	0·871	0·868	0·870
Acid value	162·0	121·3	3·5	13·1	1·2	20·4	12·3
Saponification value	197·4	203·1	255·0	256·5	256·5	252·4	252·4
Iodine value	75·1	65·4	13·6	13·7	11·4	13·7	11·0
Hehner value	97·0	—	—	—	—	87·7	—
Reichert-Meissl value.............	1·65	—	6·8	8·3	8·2	7·1	—
Solid. pt. of fatty acids	31·0° C.	—	19·8° C.	21·0° C.	20·2° C.	19·7° C.	—
Unsaponifiable matter, %	0·95	—	0·24	0·28	0·23	0·28	—
Polenske value	—	—	—	15·4	—	12·5	—

The residual meal from the extracted kernels was free from alkaloids and cyanogenetic glucosides, and had the following composition recalculated on a basis of 10% of fat :—Moisture, 9·2 ; crude proteins, 21·7 ; fat, 10·0 ; starch, etc., 38·8 ; fibre, 15·6 ; and ash, 4·7%. Nutrient ratio, 1 : 2·9 ; food units (starch+2·5 times the sum of fat and proteins), 118. The amount of proteins was higher and that of the the fibre lower than in the case of palm-kernel meal (see also this J., 1913, 797).—C. A. M.

Cacao butter ; New adulterant of ——. C. Grimme. Chem. Rev. Fett-Ind., 1914, **21**, 47—49, 74—75.

The new adulterant of cacao butter has not been identified and cannot be detected by determining the ordinary chemical characters of the fat. The physical properties of the adulterated fat and of the fatty acids obtained from it are, however, distinctly different from those of pure cacao butter. Adulterated samples yield brownish-yellow fatty acids having a coarse granular crystalline structure, the surface being irregular and lumpy, whereas fatty acids from pure cacao butter are of a light yellow colour and always solidify in fine crystals. The best evidence of the presence of the adulterant is obtained by determining the critical temperature of solution in glacial acetic acid (5 c.c. of molten fat and 5 c.c. of acetic acid), which is 76°—80° C. for pure cacao butter, whereas an adulterated sample gave 35° C. By allowing a solution of 10 grms. of the fat in 30 c.c. of a mixture of 3 parts of dry ether and 1 part of absolute alcohol to stand for half an hour at 10° C., an oily product was obtained which, on recrystallisation from the same solvent, melted at 39·7°—40° C. Under similar conditions pure cacao butter gave directly white crystals which melted at 46°—52° C. and after recrystallisation at 56°—57·4° C.—J. A.

Oils ; Hydrogenation of ——, and synthetic fatty acids [from petroleum]. M. Colletas. Les Matières Grasses, 1914, **7**, 4151—4153.

At the Vereinigte Chem. Werke at Charlottenburg, hydrogenation is effected at 100° C. under a pressure of 2 to 3 atmos. by means of 0·00002 part of palladium chloride in the presence of an alkali. The loss of catalytic agent is from 5 to 7% of the weight taken, which corresponds to an expense of 1·60 francs per 100 kilos. of fat (about 7¾d. per cwt.).

The synthetic production of fatty acids from liquid hydrocarbons by the process of Zelinsky is commercially applicable, but the cost of the product is still too high. The crude petroleum is chlorinated and dissolved in anhydrous ether, and the solution treated with magnesium and a catalytic agent (iodine, methyl iodide, aluminium salts, hydrochloric acid), and subsequently, when cold, with a current of carbon dioxide. The fatty acids, etc., are then liberated from the magnesium salts by treatment with dilute acid.—C. A. M.

Liquid from solid fatty acids ; The Fachini-Dorta method of [approximately] separating ——. A. de Waele. Analyst, 1914, **39**, 389—391.

Separation of the liquid and solid fatty acids by treating the potassium soaps with acetone (this J., 1912, 397) is more rapid and complete than lead-ether methods, whilst the liquid fatty acids undergo less oxidation in the process The following modification is recommended :—Abou 10 grms. of the dry fatty acids are dissolved in 90 c.c of anhydrous acetone at 25° C., 10 c.c. of $N/1$ potassiu hydroxide solution run in with constant stirring, and th flask corked and immersed in ice-water for 3 to 4 hour Its contents are then filtered through a Buchner funne and the residue washed with anhydrous acetone at 0° until colourless, and then pressed to remove the solven The flask is rinsed with dilute potassium hydroxide sol tion, the washings added to the solid cake, the soa dissolved in water, and the solid fatty acids liberate transferred to a weighed beaker, and dried at 100° until constant in weight. The liquid fatty acids a separated from the acetone solution by adding an equ volume of water, and 30 to 50 c.c. of ether, acidifyin with hydrochloric acid, and washing and evaporatin the ethereal layer. The following amounts of solid fatt acids were thus obtained :—Linseed oil (Calcutta seed 9·1% with iodine value, 16·4 ; (Baltic seed), 6·6%, iodi value, 20 ; Soya bean oil, 13·8%, iodine value, 12·

Para rubber seed oil, 16·3%, iodine value, 10·7; China wood oil (varied considerably) 54·1%; crude menhaden oil, 23·5%, iodine value, 20·2. The solid stereo-isomeride of elæomargaric acid from polymerised China wood oil formed a potassium soap which was practically insoluble in 90% acetone, but had an iodine value of 157. Both this method and the lead-ether method are therefore inapplicable to polymerised oils. No diminution of solid fatty acids takes place during oxidation of drying oils until solid, unless a lead drier (which precipitates part of the solid fatty acids as lead soap) is present. In the case of oxidised oils the sample is saponified, and the fatty acids liberated by treatment with petroleum spirit and hydrochloric acid. The precipitated "oxidised acids" are re-dissolved and re-precipitated to remove any unoxidised fatty acids mechanically precipitated, the united petroleum spirit solutions evaporated to dryness, and a weighed quantity of the residue treated with acetone etc., as described.—C. A. M.

Oils; Insoluble bromide value of ——. J. A. L. Sutcliffe. Analyst, 1914, **39**, 388—389.

In reply to the criticisms of Gemmell (this J., 1914, 756) the author lays stress upon the point that the factor (0·63 I.V.—78) does not vary if the conditions described in his note (this J., 1914, 147) are exactly followed. A temperature of 11° C. will prevent the formation of substitution compounds. Before filtration the contents of the flask should be cooled below 5° C., the red ethereal solution decanted, and the bromides washed with chilled ether. When dried they should be white and crumble readily. Certain sorts of bromine yield dark horn-like bromides, and should be rejected. The accuracy in duplicate determinations is usually within 1%.—C. A. M.

New copra drying process. Oil, Paint, and Drug Rep., Sept. 14, 1914. [T.R.]

An American engineer at Manila has devised a small copra drying machine of a capacity of from 800 to 1000 coconuts at one filling. The nuts are set on wire trays and heated air at 270° F. is forced through and over them. It is claimed that the value of the dried product is greater than that done by the old process.

Presses for oleaginous seeds and analogous material; Means for preventing shaking and jarring in —— during the discharge of the oil-cakes. Harburger Eisen und Bronzewerke Akt.-Ges. Fr. Pat. 468,153, Feb. 7, 1914.

SUDDEN jarring of the parts of the press raised with the oil-cake is prevented by directing the pressure (by means of an outside device) against buffers at the sides, so that after the discharge of the oil-cake the pressure is retained and no sudden movement of these parts can take place. —C. A. M.

Fats and oils; Process of treating ——. [*Catalytic oxidation.*] Gebr. Strobentz Fabriks-Act.-Ges. für Chem. Farben, Produkte, Lacke und Firnisse and L. von Kreybig. Fr. Pat. 468,352, Feb. 12, 1914. Under Int. Conv., Feb. 17, 1913.

To effect rapid decolorisation and oxidation, oils, etc., are mixed with oxides of metals of the iron group (especially cobalt oxides), and a current of air is drawn through the mixture at about 120° to 130° C.—C. A. M.

Oils; Process of hydrogenating ——. G. Calvert. Fr. Pat. 468,426, Feb. 9, 1914. Under Int. Conv., Aug. 12, 1913.

THE hydrogen and hot oil are mixed under pressure in a closed vessel by means of an agitator or circulating pump, worked by an electric motor which is contained in a communicating chamber. The passage between the two chambers may be surrounded by a cooling jacket.—C.A.M.

Treatment of plastic materials [*soap, clay, etc.*]. Fr. Pat. 468,002. *See* I.

Producing a varnish with the aid of semi-drying oils, such as fish oil, for use in the manufacture of oil-cloth and linoleum. Fr. Pat. 468,003. *See* XIII.

Manufacture of emulsions [*for margarine*]. Eng. Pat. 19,344. *See* XIXA.

Process for submitting liquids to the action of ultra-violet rays. Fr. Pat. 468,216. *See* XIXB.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Oil paint vapours; Toxicity of ——. C. A. Klein. Chem. World, 1914, **3**, 252—254.

THE toxic action of the vapours from drying paints was attributed by Armstrong and Klein to the volatile thinning constituent (this J., 1913, 320) and by Gardner (this J., 1914, 266, 363) to the presence of carbon monoxide in the vapours. It is now pointed out that Gardner's conclusions are fallacious, since the formation of the carbon monoxide must be ascribed to the interaction of the formic acid in the vapours and the fuming sulphuric acid through which the vapours were passed to absorb organic compounds. Quantitative determinations of the carbon monoxide by Gardner's method might indicate the rate of drying of a paint, but have no value as an index of the toxicity.—C. A. M.

Resin acids; Stability of —— at slightly elevated temperatures. A correction. C. H. Herty and H. L. Cox. J. Ind. Eng. Chem., 1914, **6**, 782.

FURTHER experiments have shown that the resin acids of *Pinus heterophylla* (Cuban or slash pine) yield no carbon dioxide when heated at 140° C. in a current of dry nitrogen for 1 hour, if they be perfectly dry and protected from oxygen during preparation. (Compare this J., 1909, 318.) —A. S.

Transformer oils. Brauen. *See* IIA.

PATENTS.

White lead; Process of producing ——. E. Euston, St. Louis, Mo. U.S. Pats (A) 1,106,793 and (B) 1,106,794, Aug. 11, 1914; date of appl., Sept. 10, 1913.

(A) ACID and neutral and (B) alkaline and neutral solutions of basic lead acetate are separately treated with carbon dioxide and the respective precipitates mixed. In both cases the pigments contain 11·0 to 14·5% CO_2.—C. A. M.

Pigment and process of manufacture. J. Gevers. Fr. Pat. 468,697, Feb. 10, 1914.

A SUBSTITUTE for white lead is composed of zinc sulphide, 35; barium sulphate, 20; and alumina, 5 parts; and is used with a medium consisting of linseed or olive oil, 35; driers, 2½; and turpentine, 2½ parts.—E. W. L.

Varnish; Process for producing a —— with the aid of semi-drying oils, such as fish-oil, for use, more particularly, in the manufacture of oil-cloth and linoleum. E Girzik. Fr. Pat. 468,003, Feb. 3, 1914. Under Int. Conv., April 8, 1913.

FISH oil, or other semi-drying oil, is freed from fatty acids by neutralising with caustic alkali or lime, and separating the salts from the oil. Any excess of alkali is carefully neutralised by means of acid, and the neutral purified oil is polymerised by heating, with or without the addition of a drier.—E. W. L.

Varnish; Manufacture of ——. G. Cuneo. Fr. Pat. 469,144, March 2, 1914. Under Int. Conv., March 3, 1913.

A VARNISH for covering the bottoms of ships is obtained by grinding with a liquid varnish a mixture of organic or inorganic fluorine compounds with the ordinary mineral pigments. It may contain, for example, varnish (a mixture of resin and benzene), 50; fluorine compounds, 25; and oxide of zinc, iron, etc., 25%.—E. W. L.

Plastic material. A. Chanard, St. Claude, France. Eng. Pat. 14,125, June 18, 1913. Under Int. Conv., July 6, 1912.

A MIXTURE of a resin (*e.g.*, 1000 parts of sandarac) with naphthol (1000 parts) is melted, and incorporated with a mixture of albuminoid material (casein) with, say, 20% of hydrated sodium carbonate, and the homogeneous product is moulded and treated with a hardening agent (50% formaldehyde solution). Resins such as Canada balsam may be used to obtain a transparent product, and inert loading materials, especially antimony oxide and metastannic acid, may be introduced.—C. A. M.

Plastic masses; Process for the manufacture of —— more particularly for insulating purposes. A. Regal. Fr. Pat. 468,241, Feb. 9, 1914. Under Int. Conv., March 7, 1913.

A PLASTIC mass suitable for insulating purposes, is prepared by heating a mixture of phenol 2, formaldehyde 1, sodium carbonate 0·2, and soluble glass 0·5 to 1 part on a water-bath until homogeneous, then heating the product in hot water and allowing to settle in cold water. The mass can be moulded at 40° C., and a layer 1·3 mm. thick will withstand a pressure of 12,000 volts. Sodium aluminate or zincate or aluminium acetate may be employed instead of soluble glass, each of these salts acting as a condensing agent, and being at the same time decomposed into acid and base, whereby mineral matter is precipitated throughout the mass.—E. W. L.

Diphenols and triphenols and their derivatives; Process for obtaining solid products by condensation of ——. A. Labbé. Fr. Pat. 468,879, May 5, 1913.

CATECHOL, resorcinol, quinol, pyrogallol, etc., are treated with a cold 40% solution of formaldehyde in presence of an acid: the mass soon becomes gelatinous, and after some hours is converted into a homogeneous, elastic substance. Hard products may be obtained by diluting the formaldehyde solution with half its volume of water. They are insoluble in water and organic solvents, unattacked by acids and alkalis, and are non-inflammable. The addition of acetone or glycerin to the formaldehyde results in the production of transparent masses. The physical properties of the products may be further modified by incorporating carbohydrates or cellulose.—T. F. B.

Paint for protecting iron, wood, and the like from sea growths; Manufacture of ——. M. Rappard, Den Helder, Holland. U.S. Pat. 1,108,395, Aug. 25, 1914. Date of appl., Oct. 7, 1912.

SEE Eng. Pat. 22,802 of 1911; this J., 1912, 347.—T. F. B.

Rubber; Process and apparatus for the extraction of —— [from the leaves of plants]. A. Caubel, C. Peigniet-Amaury, P. Quilici and H. Pannard. Fr. Pat. 468,245, Feb. 9, 1914.

THE fallen leaves of rubber plants are dried, coarsely crushed, and extracted with a mixture of 2 parts of carbon bisulphide and 1 part of benzene, to which is added 5% each of chloroform and sulphur chloride. The extraction apparatus consists of an upper vessel containing a removable bucket with perforated bottom, and communicating with a lower vessel by means of a large valve or cock. The lower vessel is provided with an internal heating coil, and the upper portions of the two vessels are connected to opposite ends of a condensing worm. The solvent is left in contact with the leaves in the upper vessel for 6—8 hours, and is then run off into the lower vessel, where it is heated by means of the steam-coil, the vapours condensing in the upper vessel and continuing the process of extraction. After 3 hours the bucket of leaves is removed and a fresh one inserted in its place. The solvent is then distilled from the lower vessel through the condensing worm into the upper vessel, and the process of extraction repeated The rubber is removed from the lower vessel.—E. W. L.

Rubbered fabrics and similar articles: Preservation of ——. W. E. Muntz. Fr. Pat. 468,493, Feb. 16, 1914. Under Int. Conv., Feb. 26, 1913.

To protect the fabric of rubber-coated materials from the action of sulphurous and sulphuric acids produced by oxidation of the sulphur in the rubber, the fabric is impregnated before being coated with rubber, with a substance which will combine with the acids to form innocuous compounds. For instance, cotton cloth is treated with a 3% solution of barium hydroxide, under reduced pressure, for 15 min., allowed to drain for 3 mins., and then immersed in a 3% solution of ammonium carbonate for 5 mins., after which it is dried at the ordinary temperature.—E. W. L.

Waterproofed [rubber-coated] materials; Manufacture o ——. M. Frankel und Runge. Fr. Pat. 468,755, Feb 20, 1914. Under Int. Conv., Aug. 14, 1913.

FABRICS may be impregnated or proofed with reclaime rubber by making use of the emulsion obtained when th first product of certain methods of reclaiming (see Alexander, this J., 1910, 1025) is steam-distilled in order t remove the solvent. The proofed sheet thus obtaine does not require to be vulcanised. —E. W. L.

Manufacture of fabrics for outer covers for pneumati tyres and envelopes for balloons. Eng. Pat. 22,06 *See* V.

XV.—LEATHER; BONE; HORN; GLUE.

Glue from hides; Manufacture of ——. V. Cambo Les Matières Grasses, 1914, 7, 4153—4155.

THE parings of ox-hides from the tan yards are mixed wit tendons, ears, and other refuse and sold under the name *carnasses*, to be used in the manufacture of a strong gl of reddish colour, whilst the similar parts of calves a heifers yield a glue of very superior quality. The fragmen from the skins, etc., of sheep and goats, which are l frequently met with in commerce, yield a more yellow glue, the value of which is often reduced by the presence of too much fat. In general, the glue derived from the hides of young animals is superior to that from old animals, the yield is larger and the product contains much less fat. The quantity of glue calculated on the dry material ranges from 40 to 60%. A glue of inferior quality is obtained from the shavings of the skins, which are contaminated with fat, hair, etc., and are sold under the name of *poussures*. The skins of rabbits, hares, cats, rats, and other small mammals, and the cuttings from glove manufacture yield a glue held in high esteem by plasterers (*Colle Tottin*). The fluid fish glues are largely prepared from the skins of the haddock. The plant required for the manufacture of glue from skins is much simpler than in the case of bone glue. The skins are soaked for 72 hours in lime water, and are then transferred to a perforated rotating drum of iron or wood through the axis of which a current of water is passed. After washing for 1 hour the skins are soaked in lime water (1° B., sp. gr. 1·007) for a week, washed in the drum, and again soaked for 3 to 5 weeks. They are next washed until the washings are quite clear, soaked for 12 hours in an acid bath (preferably 1% phosphoric acid free from iron) to remove the last traces of lime, then transferred to a sulphurous acid bath (1° B., sp. gr. 1·007) for 10 to 15 hours, and thoroughly washed. They are then ready for the extraction of the glue in a hot water tank.—C. A. M.

Patents.

Tanning skins; Compounds for —— and process of making them. L. Pollak, Aussig, Austria-Hungary, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 1,107,107, Aug. 11, 1914; date of appl., June 26, 1914.

Condensation products containing sulphur are obtained by the interaction of a monohydroxy phenol (*e.g.*, 5 parts of phenol), sulphuric acid (5 parts of 98% acid) and a carbohydrate (1 part of glucose). They give deep colorations with ferric ammonium sulphate, precipitate glue from its solutions, are precipitated by ammonium acetate and alum, and even in a solution of "normal acidity" and of 20° B. (sp. gr. 1·162) will tan skins without destroying them.—C. A. M.

Hair; Process of "converting" ——. C. H. Campbell, Chicago, Ill., Assignor to American Glue Co., Boston, Mass. U.S. Pat. 1,106,779, Aug. 11, 1914; date of appl., May 12, 1910.

The hair is digested at a gentle heat for a long time in a dilute alkaline solution, which is active only when heated. When the hair is almost all "converted," the source of heat is withdrawn, and the remainder "converted" by aid of the heat remaining in the liquor. The "converted" hair is dried in thin films by the application of "high heat" for a short time. (See also U.S. Pats. 1,106,777 and 1,106,778; page 965.)—A. S.

XVI.—SOILS; FERTILISERS.

Plant growth and nutrition; Some accessory factors in ——. W. B. Bottomley. Roy. Soc. Proc., 1914, **88** B, 237—247.

The substance or substances which confer on "bacterised peat" (see this J., 1913, 878, 919, 920; 1914, 366) its stimulative action on plant growth, are soluble in alcohol and in water. If an alcoholic extract of bacterised peat be evaporated to dryness *in vacuo* and the residue treated with water, the aqueous solution even after being boiled for 5 mins. exhibits very strong stimulative action, whereas similar extracts made from the original raw peat are inactive. The humic acids of peat are converted into soluble humates by the bacterial treatment, but the stimulative activity does not appear to be due to these, for extracts made from raw peat previously saturated with a 1% solution of sodium carbonate and dried, are inactive. Like the vitamines of Funk, which exert a similar stimulating effect on animal growth, the active substances of bacterised peat are precipitated (without loss of activity) by phosphotungstic acid and by silver nitrate and baryta. From an extract of 7 kilos. of bacterised peat, only 12 grms. of phosphotungstic acid precipitate (freed from reagents) were obtained, and from this by further precipitation with silver nitrate and baryta only 0·2452 grm. (freed from reagents); but an aqueous solution of the latter, at a concentration of 0·35 part per million, added at intervals of a week to wheat seedlings grown in sand moistened with Detmer's complete food solution increased the gross weight of the plants obtained after 7 weeks by 50% and their dry weight by 17·7%. The effect of the solution of the "silver fraction" on water cultures (Detmer's solution) of wheat seedlings was still more marked. Although all the plants were well aerated and the solutions were changed twice a week, the control plants weighed less at the end of 50 days than at starting, whereas the weight of those treated with the active solution had increased by more than 50%. In similar experiments with young seedlings from which the seeds had been removed, the difference between the treated and untreated plants was even greater, probably because during germination it is one of the functions of the seed to produce substances, similar to those formed in peat by the action of certain soil bacteria, which enable the young plant to utilise the food materials present. The formation of such substances during the bacterial decomposition of organic matter in the soil, *i.e.*, during the formation of humus, explains the beneficial effect of farmyard and other organic manures on crops.—J. H. L.

Aldehydes in garden and field soils; Occurrence of ——. O. Schreiner and J. J. Skinner. J. Franklin Inst., 1914, **178**, 329—343. (See also this J., 1913, 546.)

The aldehydes were extracted by treating about 14 lb. of soil with 8 litres of 3% caustic soda solution for 6—8 hrs., acidifying the alkaline extract, filtering off the humus precipitate, shaking the acid filtrate with ether, and treating the ether extract with concentrated sodium bisulphite solution. The bisulphite solution was then acidified, the sulphur dioxide expelled with air, the solution extracted with ether, the extract evaporated and the resinous or oily residue purified by dissolving in water and extracting again with ether. Of 14 garden and greenhouse soils which had become unfertile, and 60 field soils, half of which were unproductive, from various parts of the United States, 5 of the garden soils and 12 of the field soils, yielded aldehydes. The aldehydes when added to distilled water and nutrient solutions in which wheat seedlings were grown, proved distinctly harmful, causing a diminished growth both in the stems and roots of the plants.—J. H. J.

Sulphur; Influence of —— on soil acidity. H. C. Lint. J. Ind. Eng. Chem., 1914, **6**, 747—748.

Laboratory tests were made in which a quantity of sulphur equivalent to 1000 lb. per acre-foot was added to the soil, the moisture content of which was kept at about 20% during the experiment. The acidity increased continuously up to the end of the eighth week, after which there was little change. The excess acidity over that found in similar tests with soil to which no sulphur was added, corresponded with the quantity which would be formed by oxidation of the sulphur. Oxidation of the sulphur was more rapid with a sandy loam than with a heavy clay loam soil and was also favoured by keeping the soil moist.—A. S.

Nitric and nitrous acids ; Influence of weather conditions upon the amounts of —— in the rainfall near Melbourne, Australia. V. G. Anderson. Brit. Assoc. (Sect. B.), Australia. 1914. Chem. News, 1914, **110,** 127.

The concentration of nitric acid in the rainfall was greatest in summer and least in winter, whilst that of nitrous acid was greatest in winter and least in summer. The ratio of nitric to nitrous nitrogen was highest in summer and lowest in winter. The relation between this ratio and the temperature indicated that the acids are produced from atmospheric nitrogen peroxide : in hot weather the nitrous acid is rapidly converted into nitric acid. The concentration of total oxidised nitrogen (nitric plus nitrous) varied inversely as the rainfall ; the product of the concentration and the rainfall, and the total weight (per unit area) of oxidised nitrogen precipitated with rain falling during 24 hours, were constant ; so that the amount of oxidised nitrogen per acre carried by rain falling on any day is a function of the type of weather, and, within certain limits, is independent of the amount of rainfall. The amount of oxidised nitrogen thus deposited for nine distinct types of weather ranged from 1·5 to 35·0 lb. per 1000 acres.—A. S.

XVII.—SUGARS ; STARCHES ; GUMS.

Beet seed ; New German standards for the trade in ——. W. Edler. Fühling's Landwirtsch. Zeit., 1914, **63,** 268—277 ; Monthly Bulletin of Agricultural Intelligence, 1914, **5,** 852—857.

A number of interested bodies have drawn up a new set of standards, embodying modifications that have been proposed from time to time, and including instructions for sampling and the calculation of the deduction to be made in the case of seeds not coming up to standard, but yet saleable. *Standards for beet seed.* (1) The seed must be delivered in good condition, fit for use, and, except for the screening necessary in cleaning, not graded according to the size of the clusters. It must belong to the variety specified. (2) It should contain at least 85% of dry substance, but is saleable with 83%, in which case the excess of moisture must be allowed for (see Clause 5 below.) (3) The purity should be at least 96%, and clusters passing through a 2 mm. (0·08 in.) sieve must be considered as impurities. Seed of 94·5% purity is saleable, but the value must then be calculated by the formula given under (5), for the purpose. (4) In the germination test, 1 kilo. (2·2 lb.) must give a minimum of seedlings, as follows : (a) large cluster, 60,000 ; (b) medium cluster, 65,000 ; and (c) small cluster, 70,000 ; of which number 70% must appear within 14 days. One hundred clusters must give in 14 days a minimum of seedlings, as follows : (a) large cluster, 80 ; (b) medium cluster, 75 ; and (c) small cluster, 70. Large cluster seed contains not more than 40 clusters per grm. ; medium, 41—50, and small 51 or more. (5) The reduced prices for seed which is saleable but does not come up to the specification of clauses (2) or (3), is calculated according to the following formula :

$$\frac{\text{price agreed upon} \times \text{value of seed delivered}}{\text{guaranteed value}} ;$$

while if both (2) and (3) require reduction, the price is obtained by the formula :

$$\frac{\text{price agreed upon} \times \text{actual dry matter} \times \text{actual purity}}{85 \times 96}.$$

(6) In the absence of any other agreement, samples must be taken within three days of the delivery of the seed by a sworn sampler, according to the following directions : *Sampling beet seed.* If the lot numbers more than 100 sacks, a sample must be taken from at least every twentieth sack ; if there are between 20 and 100 every tenth ; while for less than 20 every other sack must be sampled. At the request of one of the parties concerned, all the sacks to be sampled may be turned out ; or if this be not practicable, the fact must be noted in the report. The average sample made up from the small portions is thoroughly mixed, then divided into separate samples according to the number of analyses required. The samples for the determination of moisture and purity are to be enclosed in clean and dry air-tight vessels of glass or tin, openings being sealed with wax, rubber cement, etc. ; ground-glass stoppers should be greased. The seed must b tightly pressed into the vessel, and each sample should weigh about 200 grms. The samples (about 200 grms. for the germination test are to be preserved in cloth bags and not in air-tight vessels. The sampler must despatc the samples within 24 hours, one set being sent to th purchaser, one to the vendor, and a third retained.—J.P.O

[Sugar] Cane ; Disinfection of —— before planting. A. H Rosenfeld and T. C. Barber. Intern. Sugar J., 1914 **16,** 410—412.

Experiments at the Tucumán Experiment Statio showed that a preliminary treatment of plant and ratoo canes with Bordeaux mixture is not profitable, the sligh increase in the crop being insufficient to compensate th extra expense.—J. P. O.

Sugar-cane juice ; Potash content of ——. C. S. Taylo Agric. J. India, 1914, **9,** 236—246.

From the beginning of December 1913 until the middl of February 1914, fortnightly determinations of th potash content of the juice of Khari cane grown o various plots were made. The perchlorate method o estimation was used, sulphates being first removed wit barium chloride. The mean sugar content of 38 sample of juice was 13·79 and the mean potash content 0·191% There was very little correlation between potash conten and sugar content. Similar determinations were made wit juice from different varieties of cane grown under simila conditions. Here there was some evidence that a hig potash content was accompanied by a low sugar conten The mean potash content of the 38 different varieti examined was 0·174, varying from 0·060 to 0·272% an average sugar 17 to 18%.—L. J. de W.

Raw sugars ; Valuation of ——. F. G. Wiechman Sugar, 1914, **16,** No. 8, 27—31.

Seyffarth's proposed method (Z. Ver. deut. Zuckerind 1894, 399) of valuing raw beet sugars by means of t so-called "normal organic non-sugar" (total non-sug minus ash) has been examined by the author to t its applicability to raw cane sugars. The value 2·97, which was shown to be valid for beet sugars, does not hold good for cane products, but definite constants may be established for the different classes, as centrifugals (1·53—1·72), muscovados (1·60—2·34), mats (1·42—1·57), and molasses sugars (1·75—2·11). Having ascertained the class constant, the "organic non-sugar" may be calculated by the formula: $\frac{100-\text{polarisation.}}{\text{class constant}}$ In calculating the rendement of a raw sugar any formula taking into account the ash alone must be inadequate, since the organic non-sugar also has a melassigenic function, and the general use of a yield formula taking into consideration both factors is advocated. —J. P. O.

Filtration ; Cause of difficult —— in the filter-presses [when working the carbonatation process in the beet sugar factory]. H. Wesely. Oesterr.-Ungar. Zeits. Zuckerind., 1914, **43**, 66—68.

Difficult working of the filter-presses in the beet sugar factory is stated to be caused by the presence in the scums of minute gas bubbles, which impart a sandy feel, hitherto generally believed to be caused by fine grit originating from the lime used for defecation. These gas bubbles obstruct the pores of the cloths, and render easy filtration impossible, notwithstanding the application of high pressure. To avoid their presence in the scums, the use during carbonatation of the stirring appliances formerly generally employed is advocated.—J. P. O.

Gum ; Determination of the —— in [cane] molasses. L. G. L. Steuerwald and T. van der Linden. Archief Suikerind. Nederl.-Indië, 1914, **22**, 1033—1071 ; Intern. Sugar J., 1914, **16**, 430—431.

Approximate results only are obtainable by precipitation with strong alcohol, as pectins and certain organic acid compounds are also precipitated. More reliable and concordant results are obtained by the following process: 50 grms. of the sample are dissolved in 100 c.c. of water, and 20 c.c. of the solution are treated with a mixture of 150 c.c. of 95% alcohol and 30 c.c. of 6*N* hydrochloric acid. The resulting precipitate is collected on a tared paper, washed with 95% alcohol until neutral, and treated first with warm water, and afterwards with 10% hydrochloric acid, again washed with warm water till neutral, dried at 105° C., weighed, and incinerated, the weight of ash being deducted to give the net weight of true gum. The total gummy substances are higher in defecation than in carbonatation molasses.—J. P. O.

Yield of alcohol from cane molasses of different sources. Owen. *See* XVII.

Patents.

Sugar ; Process for refining ——. J. G. Kremers, Milwaukee, Wis. U.S. Pat. 1,107,172, Aug. 11, 1914 ; date of appl., July 30, 1913.

Impure sugar solutions are defecated with lime, and treated first with carbon dioxide until neutral to phenolphthalein, and then with sulphur dioxide until slightly acid to litmus.—W. P. S.

Levulose ; Process for transforming —— into mannitol by hydrogenation. T. Lupieri and H. Mayer. Fr. Pat. 468,920, May 6, 1913.

Levulose is hydrogenated (*a*) by electrolysing a solution of the sugar in dilute sulphuric acid or alkali between inert electrodes, (*b*) with hydrogen at a pressure of at least 3 atmospheres in presence of finely divided metals or metallic oxides, at not above 70° C., (*c*) with nascent hydrogen produced by the action of rhodium black or other finely divided allied metals on formic acid, or (*d*) continuously, by the action of sodium amalgam produced electrolytically. —L. E.

Manufacture of ethers of carbohydrates of the type $(C_6H_{10}O_5)_n$ and their derivatives. Fr. Pat. 468,162. *See* V.

Production of glucose and alcohol from sawdust and other cellulosic material. Fr. Pat. 468,188. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Beer worts ; Influence of temperature on saccharometer readings in ——. G. Rossi. Annali Chim. Appl., 1914, **2**, 27—35.

From the results of the author's experiments with different types of saccharometers, together with results of other investigators, the following table has been constructed, from which the true value at the normal temperature of 17·5° C. can be calculated from saccharometer readings at other temperatures, with sufficient accuracy for practical purposes in the case of beer worts of average gravity:—

Temp.	Correction.		Temp.	Correction.		Temp.	Correction.	
	By weight.	By vol.		By weight.	By vol.		By weight.	By vol.
° C.			° C.			° C.

Methyl alcohol; Detection of ——. A. Rinck. Z. Unters. Nahr. Genussm., 1914, **28,** 98—99.

THE solution under examination is slowly distilled in a flask through the cork of which is passed a silica tube bent at an angle of 60°, a copper spiral being placed in the tube just below the bend. The distillate is collected in a small flask immersed in ice-water, and the first 1 c.c. is tested for formaldehyde with 5 c.c. of sulphuric acid containing morphine. The test will detect 0·05 grm. of methyl alcohol.—C. A. M.

Preparation of α-methyl- and α-ethyl-glucosides. Aubry. *See* XX.

PATENTS.

Mash filters. J. Schaefer, Frankfort-on-Maine, Germany. Eng. Pat. 17,028, July 24, 1913. Under Int. Conv., Aug. 10, 1912.

A FIXED head, with inlet and outlet valves controlling the inflow and outflow passages formed by the holes in the filter-plates, is placed centrally between two series of filter-frames extending in opposite directions. The filter frames are pressed together by any suitable means and are so constructed that free access is provided on one side of each filter-cake for the sparge water to the whole surface of the cake, and a space is provided on the other side of each cake for the spargings to flow away from the whole surface of the cake. Each series of filter-frames is connected with a common canal for admission of the sparge water to each cake and to another common canal for withdrawal of the spargings from each cake, the rate of flow of water and spargings in each canal at each cake being substantially the same. The sparge water enters, and the spargings leave, at the same end of the series of frames; hence the maximum flow and minimum pressure are maintained at one end of the series of frames, and the minimum flow and maximum pressure at the other end, and the inflow and outflow pressures on the sides of each cake are substantially the same.—L. E.

Yeast; Means for handling, skimming and pressing ——. W. Scott, Birmingham. Eng. Pats. 21,925, Sept. 29, 1913, and 7729, March 27, 1914.

THE yeast is transferred from the fermentation vat to a closed vessel from which it is forced by gas pressure into a filter-press; the filtrate is returned to the fermentation vat. The pipes for conveying the yeast to the filter-press and the filtrate therefrom to the fermentation vat may be cooled by water-jackets.—W. P. S.

Brewery; Vat for the —— or for other purposes. O. Wehrle. Fr. Pat. 468,746, Feb. 20, 1914.

THE vat is divided by a number of arched partitions into superposed independent compartments. Successive compartments are joined together by iron rings to which the arched partitions and the edges of the compartments are soldered; or, the connecting rings may be provided with projecting rims which engage with, or are bolted to corresponding rims at the edges of the compartments.

—L. E.

(A) *Wines and* (B) *spirits, marcs, brandies, etc.; Process for artificially ageing —— by radioactivity.* H. Farjas. Fr. Pats. (A) 468,700 and (B) 468,701, April 30, 1913.

A MIXTURE of radioactive material, freed from any injurious constituent, and a plastic substance such as cement, is moulded into a suitable shape, dried, and immersed in the liquid to be treated, whereby ageing is effected much more rapidly than by storage.—L. E.

Distilling apparatus; Continuous ——. A. L. Obrador Manila, Philippine Islands. U.S. Pat. 1,106,832 Aug. 11, 1914; date of appl., Aug. 31, 1911. Renewe April 29, 1914.

A SERIES of boilers is connected with a main fractionatin column and with an auxiliary column. The vapours fron the boilers pass up the auxiliary column and thence to th main column, and the " mash " is fed through the auxiliar column into the first of the series of boilers.—W. H. C.

Rectification; Process for the continuous treatment of th tail products of ——. P. Marin. Fr. Pat. 467,83 April 7, 1913.

THE tail products are admitted to a rectifying colum fitted with at least 34 plates so that the ethyl and am alcohols may be completely separated in a single operatio The amyl alcohol accumulates between the 7th and 12t plates, and when it separates in drops, the liquid is wit drawn from this part of the column. The volume amyl alcohol subsequently decanted from the liqui should amount to about 25% of the total volume of liqui withdrawn.—L. E.

Glucose and ethyl alcohol from sawdust and other cellulos materials; Production of ——. A. de Posnansk Fr. Pat. 468,188, April 17, 1913.

THE process is essentially the same as that described Fr. Pat. 464,502 of 1913 (this J., 1914, 497). After bei treated with ammonia and washed, the material thoroughly mixed with the saccharifying agent (sulphur acid) before it is introduced into the autoclave saccharification. The saccharified product is fr from sulphuric acid, preferably by barium carbona and purified by one of the methods previously describ or by freezing it and then separating it from the snow th formed.—L. E.

Liquids [wines, spirits, etc.]; Treatment of —— for improving the quality. C. Henry, Coye, France. Eng. Pat. 19,346, Aug. 26, 1913. Under Int. Conv., Aug. 27, 1912.

See Fr. Pat. 459,141 of 1912; this J., 1913, 1167.—T. F. B.

Wines, liqueurs, and other vegetable extracts; Process of clarifying, ageing, and refining ——. E. Monti, Turin, Italy. U.S. Pat. 1,108,777, Aug. 25, 1914. Date of appl., Sept. 29, 1905.

See Fr Pat. 358,287 of 1905; this J., 1906, 230.—T. F. B.

Alcohol; Process of manufacturing ——. F. Thatcher, El Paso, Texas, and L. M. Stiles, Hachita, New Mexico, U.S.A. Eng. Pat. 6775, March 17, 1914.

See U.S. Pat. 1,096,965 of 1914; this J., 1914, 659.—T.F.B.

XIXa.—FOODS.

Gluten; Variations of ——. Marchadier and Goujon. J. Pharm. Chim., 1914, **10**, 191—202.

Addition of foreign flours (rye, barley, etc.) to wheat flour diminishes the quantity of gluten obtainable from the latter on kneading with water (see Balland, this J., 1899, 389), and if the proportion of foreign flour is sufficiently high (*e.g.*, 40% of rye) no gluten is obtained. The cause of this appears to be physical, for inorganic substances such as talc, magnesia or silica, in the form of powder, behave like foreign flours in this respect. Variations in the gluten-content of wheat flour itself, or of the wheat grain, are on the other hand probably due to deviations from the optimum proportion (3 : 1) between the gliadin and glutenin which together constitute gluten (cp. Baker and Hulton, this J., 1908, 373) and which are interconvertible, the former being a deoxidised, hydrated derivative of the latter. Such deviations may occur during the germination of wheat grains, or during the milling process if this is too vigorous and the particles become overheated. The proportion between gliadin and glutenin may also be affected by the weather conditions during the growth of wheat, and by the conditions of storage of flour. It is known that if the acidity of flour exceeds a certain small value (0·05%) the separation of gluten is to some extent inhibited, and the authors suggest that the higher gluten-content of wheat grown on virgin soil (America) as compared with that from highly manured soils, may be due to a slightly higher acidity of the grain in the latter case, arising from the large quantities of superphosphate manures employed.—J. H. L.

Casein [in milk]; The ferric alum determination of ——. H. V Arny and H. H. Schaefer. J. Ind. Eng. Chem., 1914, **6**, 748—751.

Five c.c. of milk are mixed with 5 c.c. of standardised ferric alum solution (48·2224 grms. $FeNH_4(SO_4)_2, 12H_2O$ per litre), and after 1 hour, the mixture is filtered with the aid of suction, and the precipitate washed free from soluble iron compounds. The excess of iron in the filtrate and washings is determined by digesting with 3 c.c. of 31% hydrochloric acid and 2 grms. of potassium iodide for 30 mins. at 40° C., and titrating the liberated iodine with $N/50$ thiosulphate. For rapid work the excess of iron may be determined by direct titration with $N/10$ alkali, using phenolphthalein as indicator. 1 c.c. of the ferric alum solution is equivalent to 0·05934 grm. of casein.—A. S.

Patents.

Cacao, coffee, and like seeds; Continuous pulping, washing, developing, drying, and polishing of —— and machinery or apparatus therefor. G. Watt, Lockerbie, Scotland. Eng. Pat. 15,703, July 8, 1913.

The seeds are subjected to the action of water, steam, and agitating devices until the outer pulpy coating is softened and rendered detachable; they are then washed, subjected to the action of hot water and air, with or without the addition of chemical agents, dried, and polished. The different vessels may be combined in one machine, the various parts being removable.—W. P. S.

Cacao and like seeds; Treatment or method of preparing —— and machinery or apparatus therefor. G. Watt, Lockerbie, Scotland. Eng. Pat. 13,011 of 1914; date of appl., July 8, 1913.

Cacao beans are subjected to the action of hot or cold water while contained in a perforated rotating vessel, provided with an agitator and mounted in a chamber. Chemical agents, such as potassium permanganate, vinegar, etc., are added to the water which is continuously supplied to the chamber, and air is blown into the liquid. Sterilisation may subsequently be effected by cutting off the supply of water and admitting steam until the beans are heated to 120° F. (49° C.).—W. P. S.

Tea, coffee, and the like; Means and apparatus for the production of dry extracts of ——. M. I. Bray, Sealby, A. C. T. F. Waugh, Bradford, and H. Ingle, Scarborough. Eng. Pat. 18,873, Aug. 20, 1913.

The extracts are evaporated in a chamber having a large, level, steam-heated base divided into a number of compartments supplied separately with steam so that the heat applied to different portions of the base may be varied or regulated. An anti-splash is arranged in the upper part of the chamber, which is connected with a device for exhausting the air and vapours, and the cover is fitted with observation windows.—W. P. S.

Emulsions; Manufacture of —— [for margarine]. E. V. Schou, Copenhagen. Eng. Pat. 19,344, Aug. 26, 1913.

Fat is emulsified with a liquid, such as skimmed milk, in which a gelatinous or ropy fermentation has been induced by *e.g.* inoculation with lactic acid bacteria, or with a culture of micro-organisms producing aromatic compounds and lactic acid.—C. A. M.

Foodstuffs; Process for preserving liquid ——. Ges. f. Sterilisation m. b. H. Ger. Pat. 275,871, March 1, 1913.

A small quantity of bromine or iodine in alcoholic solutions containing at least 2% of ethyl alcohol, is used as preservative. For example, 10 kilos. of egg yolks are treated with 10 grms. of iodine dissolved in 200 grms. of absolute alcohol and 200 grms. of water.—T. F. B.

XIXb.—WATER PURIFICATION; SANITATION.

London waters; Chemical and bacteriological examination of the ——. A. C. Houston. Metr. Water Board. Eighth Annual Report, April, 1914. (See also this J., 1913, 921.)

This report covers the year ended 31st March, 1914. The most notable event was the recurrence of the algal trouble in the Staines reservoirs, due this year to the growth of *Tabellaria*, which rendered the water almost unfilterable. The remedy used was to treat the water with copper sulphate and dilute it largely with raw river water.

In addition to the usual oxygen absorption test for 3 hrs. at 80° C., 4-hour tests were also made over a considerable period; they gave results 5% higher. In the case of unsatisfactory waters there is a striking parallelism between the results of a 5 mins. oxygen absorption test and the usual 3-hours test. Taking 0·1 as the basis for objecting to the quality of a water on the 3-hours test, the corresponding figure for the 5-mins. test is 0·038. The bacterial count on bile-salt agar, previously confined to the raw river water, was extended to the filtered waters. The number of bacteria found averaged less than one per c.c. The result of the test is most reliable in winter; occasionally in summer, higher results are obtained, but the colonies are not of typical appearance, and there may be a growth in the water of bacteria which are not necessarily of intestinal origin. In averaging the number of bacteria in the raw river water, all the results have been included, but at times of high flood, counts of 25,000 have been obtained, and it is considered that if these high counts were excluded, a more accurate average figure would be obtained. Further, as there is no reason why the intakes should not be closed at these times of high flood, the exclusive average figure would more truly reflect the quality of the water abstracted. Full tables with details of the chemical and bacteriological results for the raw and filtered waters throughout the year are given. It is considered that the means now adopted for the purification of the supply are such as to render the water reasonably, if not absolutely, safe for drinking purposes.—J. H. J.

River water and sewage; Search for pathogenic microbes in ——. A. C. Houston. Metr. Water Board. Tenth Research Report, June, 1914. (See also this J., 1912, 355, and 1913, 764.)

A known number of typhoid bacilli was added to samples of sewage, and by suitable means a proportion of them was again isolated. It was calculated that it would be possible to isolate one typhoid bacillus from 0·00066 c.c. of sewage, and as none was isolated from control samples of the sewage used, the conclusion is that they were absent from that amount of such sewage. The average number of other bacteria in 0·00066 c.c. of the sewage was 704, whilst the volume of raw river water containing 704 bacteria was 17 c.c. As the filtered water is about 1000 times purer than the raw water, it follows that 17,000 c.c. of the filtered water would not contain a single typhoid bacillus. For isolating the *B. typhosus* from water, a "malachite green" solid medium was superior to ox-gall and "brilliant green" liquid media. In a series of experiments upon the vitality of the *B. typhosus* in water stored at different temperatures, it was found that the bacilli and also *B. coli* lived much longer near the freezing point than at 20° C. No constant difference between the fermentation characteristics of streptococci of human origin and those from animal dung could be detected, but the number of lactose-fermenting streptococci in animal dung was very small. In examining stored water for survival of *B. coli* and other organisms, it has been objected that the diminution in the number of bacilli might be due to clumping and to adherence to the sides of the vessel, but no increase in numbers was observed after shaking the samples with lead shot or sand. Devitalisation is considered to be the chief factor in producing the changes observed under storage. In some laboratory experiments on the excess lime method of sterilisation, *B. coli* died in 7 days in tap water containing 4 parts of CaO per 100,000, whereas in the water, boiled or unboiled, without lime it survived for 25 days. Excess of free lime was necessary: in tests using just sufficient to neutralise the carbonic acid acidity, the *B. coli* was still alive after 13 days.—J. H. J.

Sewage; Clarification of —— *by fine screens.* K. Allen. Proc. Amer. Soc. Civil Eng., 1914, 40, 1839—1910.

The dividing line between coarse and fine screens is taken as being an opening of $\frac{5}{8}$ in. or 15 mm. Only screens which are cleaned above the surface of the sewage are considered, and of these there are five types. The *band screen* consists of an endless flexible band, either of wire mesh or links, which passes over upper and lower rollers. In the screen at Hamburg the links are 0·6 in. apart and are made of an aluminium alloy. The screen is inclined and revolves at the rate of 1—2 in. per sec. At the top, there is a comb or rake to pass between the links to remove the screenings. Before passing through the screen, the sewage flows through a grit chamber. The screenings removed contain H_2O 83—93%, and N 0·1—3·7% when dried At Carshalton, Surrey, a band consisting of perforated steel strips with holes of $\frac{3}{8}$ in. diam. is used. It will remove about 2·5 cub. yds. of solids per million gallons of sewage. The *wing screen* consists of an axle on which flat vanes are set radially. At Frankfort the axle has five vanes consisting of steel bars 0·4 in. apart. The screen revolves in the sewage channel which has a depression under the screen. As a vane rises out of the sewage, a rubber scraper is forced along it from the axle outwards, and the screenings are dropped on to a horizontal steel plate which transfers them to a belt conveyor. The cost is 9d. per cubic yard of screenings. At Bradford similar screens are in operation, the bars being about 0·5 in. apart. When a pair of vanes reaches the horizontal, the screen stops and a rake is introduced and withdrawn mechanically. In the *shovel-vane screen* the vanes are semi-circular and fixed between two circular plates which form the sides of the screen. The axle is hollow and partly open, and contains a belt conveyor. When a vane is in the upright position, the solids drop off on to the belt. The vanes are cleaned by a brush on the end of an arm swinging from a centre near the middle of the adjacent vane. At Strassburg where the vanes are formed of V-shaped wires, 0·1 in. apart, the suspended matter in the sewage was reduced from 211 parts per 100,000 to 78·5 parts at a cost of 3d. per cubic yard of screenings. The *drum screen* consists of a truncated cone of perforated plates or wire mesh, which rotates on a horizontal axis. There are radial plates which raise the screenings and drop them into a central hopper delivering into buckets. At Trier, Germany, the perforations in the plates are 0·1 in. diameter and 0·04 in. apart. The cost of working is 8s. 9d. per million gallons. The *Riensch-Wurl screen* consists of an annular disc surmounted by a truncated cone, both of which are perforated with slots 0·04—0·2 in. in width. The disc is mounted on an inclined shaft and is partly submerged. When raised out of the sewage, the solids are removed by brushes revolving on arms from another shaft. At Dresden where the slots are 0·08 in. wide, the solids removed averaged 1 cubic yard per million gallons and contained 84% H_2O. Fine screening of sewage is suitable in cases where there is a large body of water capable of receiving the screened sewage without further treatment. The efficiency is comparable with that of plain sedimentation tanks, 30—50% of the suspended solids being removed. The screenings contain less water and are more convenient to handle than tank sludge.—J. H. J.

External corrosion of cast-iron pipe. Pugh. *See* X.

Patents.

Pumps [*Water*]; *Process of protecting* —— *from ozone* C. Knips, Charlottenburg, Germany, Assignor to Siemen und Halske, Akt.-Ges., Berlin. U.S. Pat. 1,103,211, July 14, 1914; date of appl., July 18, 1911.

To prevent corrosion of the inner metal parts of the pump, special lubricants are employed, and a small quantity o water is supplied to the pump simultaneously with th ozonised air. This water and the ozonised air are force together through the water to be sterilised.—W. H. C.

Water; Process for clarifying and sterilising ——. C Massatsch, Assignor to Permutit-Akt.-Ges., Berlin U.S. Pat. 1,107,199, Aug. 11, 1914; date of appl., Feb. 6 1914.

The water is treated with such quantities of a perman ganate and a manganous salt as to produce a clear brow solution of colloidal manganese oxides, and is then filtere through sand.—W. P. S.

Water and other liquids or the like; Filtering of —— D. Dunbar, Glasgow. Eng. Pat. 19,142, Aug. 23, 1913

Parallel screens of wire-cloth are arranged in a chambe and two feed tanks fitted with baffle-plates are provide for supplying the water to the chamber. When th screens become clogged, they are cleansed by means ater charged with air under pressure, delivered through spraying device which is lowered between them; this praying device can be raised, lowered, or removed from ne set of screens to another as required.—W. P. S.

ater; Process of removing carbonates from ——. K. Schrempp. Fr. Pat. 468,047, Feb. 4, 1914.

ISSOLVED calcium and magnesium carbonates may be recipitated from water by heating the latter to near, or bove, its boiling point under pressure, and then, as uickly as possible, subjecting it to a low pressure. —W. P. S.

ltra-violet rays; Process for submitting liquids to the action of ——. J. de Kowalski-Wierusz. Fr. Pat. 468,216, Feb. 5, 1914. Under Int. Conv., Oct. 27, 1913.

HE liquid is sprayed by means of compressed air or steam to a series of vertical tubes arranged about a lamp nitting ultra-violet rays; the lower ends of the tubes e in connection with a collecting channel. Or, the quid may be sprayed directly into a chamber conining the lamp. Oil may be treated or mixed with ygen before being submitted to the action of the rays; bleaching effect is thereby obtained.—W. P. S.

iquids; Sterilisation of —— by ultra-violet rays. A. Douilhet. Fr. Pat. 468,617, April 28, 1913.

HE lamp is placed in the centre of the liquid to be erilised and may be surrounded by a quartz jacket order that it may be worked at a high temperature; the lamp is placed directly in the liquid, metal mounts e provided at the ends so that the electrodes are not oled. A photometer, depending on the principle that tra-violet rays pass through quartz but not through dinary glass, is used to ascertain whether the rays e traversing the liquid thoroughly. Baffle-plates in the erilising chamber cause the liquid to flow in close contact ith the lamp. The liquid, if opaque and containing fat obules, may be diluted with water before being passed rough the apparatus, and concentrated subsequently der reduced pressure; the sterilisation may be carried t at such a temperature that the fat globules are melted. —W. P. S.

wage sludge; Method and apparatus for concentrating ——. J. Grossmann, Manchester. Eng. Pat. 22,778, Oct. 9, 1913.

WAGE sludge is treated with a small quantity sulphuric other mineral acid, allowed to stand until separation s taken place, and the liquid portion drawn off. ith sludge containing about 10% of solid matter, out 0·3% of its weight of sulphuric acid may be used. e treatment may be carried out in a tank such as that scribed in Eng. Pat. 28,328 of 1911 (this J., 1913, 159). —W. P. S.

aste-water from towns and industries; Process and apparatus for removing solids from —— and for receiving the sludge in a solid state. Puech, Chabal et Cie. Fr. Pat. 468,134, Feb. 6, 1914.

E waste water is delivered on to a horizontal travelling nd of perforated metal and thence on to another band, d so on, the bands being arranged one below the other a series of steps and scrapers provided at the ends to move the residual solid matter and deliver it into ceptacles. The water is, finally, passed on to bacterial ds or on to land. The whole apparatus may be enclosed. —W. P. S.

wage sludge and similar substances; Process of treating ——. E. W. Janson. Fr. Pat. 468,864, Feb. 24, 1914.

ESSED sewage sludge is sprayed with 0·5 to 4% of its ight of petrol and is then distilled at 260°—480° C.; oils, ammonia, etc., distilling over are collected. e temperature is then raised to 650° C. and the final idue remaining in the retort is used as a manure or precipitating further quantities of raw sewage.—W.P.S.

Waste waters; Apparatus for the purification of ——. Geiger'sche Fabrik für Strassen-und-Haus-Entwässerungsartikel Ges. m. b. H. Fr. Pat. 468,763, Feb. 20, 1914.

AN inclined screen, composed of galvanised iron bars united by cross-bars, is placed in the channel conveying the waste-water. An endless chain band, carrying brushes, travels over the front face of the screen and removes the collected solids to a receptacle situated above the apparatus. Means are provided for raising the screen from the water channel.—W. P. S.

Refuse destructor. W. Ramsay, London. Eng. Pat. 19,083, Aug. 22, 1913.

THE destructor furnace consists of two conical portions connected by a vertical portion; a shoot delivers the refuse into the upper conical portion. The grate is placed at the bottom of the lower conical part and below this is an ash-pit. The air supplied to the furnace is preheated by passing it through pipes surrounding the lower part of the furnace; the fumes and combustion gases escape through a dust chamber and a flue.—W. P. S.

Industrial production of ultra-violet rays by means of [electric] sparks. Fr. Pat. 468,215. *See* XI.

Process and apparatus for the electro-chemical treatment of liquids [e.g. water]. Fr. Pats. 468,242 and 468,277. *See* XI.

PATENT CASE.

Permutite; Process of revivifying or restoring ——. G. Schweikert and A. Czeczowiczka, Vienna. Eng. Pat. 23,706 of 1912 (this J. 1913, 377, 548, 671). Repts. of Patent, Design, and Trade Mark Cases. Vol. XXXI. Appendix No. 1, Jan. 28, 1914. By permission.

THIS was an opposition to an application for the grant of a patent, on the ground that the word "permutite" used by the applicant was a registered trade mark. Permutite consists chiefly of sodium-aluminium silicate. The Comptroller-General held that the use of a registered trade mark in a specification by another was prejudicial to the rights of the registered owner, unless it were pointed out that it is a registered trade mark or is the property of a specified firm. The specification was ordered to be amended.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Nux vomica and its preparations; Determination of alkaloids in ——. M. Azadian. Ann. Chim. Analyt., 1914, **19**, 164—165.

10 GRMS. of powdered *Nux vomica* are made alkaline with 5 grms. of ammonia and repeatedly extracted with a mixture of 25 grms. of chloroform and 50 grms. of ether until all alkaloid is removed. The filtered extracts are united, concentrated, acidified with dilute nitric acid, and completely extracted with water. The acid liquid is warmed to expel volatile solvents, cooled and 10 c.c. of a 5% solution of silicotungstic acid and 10 c.c. of 10% nitric acid added. The mixture is heated to boiling, cooled and the precipitated silicotungstates of strychnine and brucine separated, washed, dried and ignited. The weight of residue multiplied by 0·498 gives the weight of alkaloid. Strychnine silicotungstate has the formula, $12WO_3,SiO_2.2H_2O,4C_{21}H_{22}N_2O_2.8H_2O$.—T.C.

Medicinal plants in England; Cultivation and collection of ——. W. A. Whatmough. J. Board Agric., 1914, **21**, 492—510.

CONTAINS information relative to the cultivation and collection of medicinal plants which grow or can be grown in England.

Cocaine ; New reaction of ——. F. Pisani. Rend. Soc. Chim. Ital., 1914, **6**, 132. Annali Chim. Appl., 1914, **2**, 51.

THE free alkaloid or its hydrochloride when heated with a few drops of concentrated sulphuric acid containing 2% of hexamethylenetetramine, gives a wine-red coloration becoming more intense as the temperature rises: after a short time the colour disappears and a brownish-grey sediment is left. The reaction, which is due to benzoic acid, and is not given by atropine, quinine, cinchonine, brucine, strychnine, morphine, apomorphine, codeine, or narcotine, is distinct with 0·001 grm. of cocaine. Papaverine under similar conditions, may also give a wine-red coloration, changing, however, after a short time, to yellow, reddish-brown, and orange: in doubtful cases papaverine may be identified by the violet coloration it gives with sulphuric acid alone, a reaction not given by cocaine.—A.S.

Lead and arsenic ; Limits of —— *in official substances and preparations.* Chem. and Drug., 1914, **85**, 492.

IN the fifth British Pharmacopœia the limiting quantities (parts per million) of lead and arsenic allowed in various pharmaceutical substances and preparations are :—

Chemical.	Parts per million.		Chemical.	Parts per million.

Syntheses in organic chemistry by means of light. X. *Behaviour of vegetable alkaloids with ketones.* E. Paternò. Gaz. chim. ital., 1914, **44**, II., 99—111.

THE alkaloids used in the experiments were nicotine, sparteine, coniine, piperine, papaverine, strychnine, and narceine, and the ketones were acetone, acetophenone, and benzophenone. In many cases the ketone was converted into the corresponding pinacone, and in several instances evidence of the formation of addition-compounds of alkaloid and ketone was obtained. Nicotine and benzo
phenone, for example, yielded a compound which crystal
lised in yellowish needles, m.pt. 151°—153° C., and corre
sponded in composition with a compound of 1 mol. eacl
of nicotine and benzophenone. A substance, probabl
an addition-compound, was also obtained from spartein
and acetophenone, but could not be isolated in a pure stat
owing to its pronounced colloidal character. Strychnin
and acetophenone gave a yellow amorphous powder, havin
marked colloidal properties, probably an addition com
pound of 2 mols. of acetophenone and 1 mol. of strychnin
From narceine and acetone, two bases were obtaine
melting at 231°—232° and 156°—160° C. respectivel
probably products of dehydration of narceine.—A. S.

a-Methyl- and a-ethyl glucosides ; Preparation of ——.
Aubry. J. Pharm. Chim., 1914, **10**, 202—207. (S
Bourquelot and others, this J., 1913, 251 ; 1914, 40).

THE following details are given for the biochemical pr
paration of a-methylglucoside in the laboratory :—18
grms. of pure methyl alcohol are mixed with a solution of 5
grms. of dextrose in 4 litres of water, and then with filter
maceration juice made from 300 grms. of bottom-ferment
tion beer yeast and 3 litres of water, and finally the who
is made up to 10 litres with distilled water, an
maintained at 18°—20° C. until its optical rotato
power has increased from 5° 18′ to 11° or 11° 30′. T
liquid is then treated with a little calcium carbonat
heated to boiling, filtered and concentrated to 5 litres
distillation under reduced pressure. The residue
treated with 50 grms. of fresh baker's yeast, and aft
all the unchanged dextrose has been fermented (about
days) the liquid is filtered, neutralised with calcium ca
bonate, heated to boiling, filtered and distilled und
reduced pressure on the water bath to complete dryne
The residue is boiled, first with 500 c.c. and afterwar
with smaller quantities of 95% ethyl alcohol, and t
boiling extracts are filtered and cooled. Crystals of a-meth
glucoside separate and may be purified by recrystallis
tion from ten times their weight of 95% alcohol. T
yield is about 150 grms. and the purified product h
$[a]_D = +157 \cdot 95°$ and m.pt. 168—169° C. On an industr
scale, where the excess of methyl alcohol can be efficien
recovered by rectification, it would be possible to obt
a somewhat higher yield by reducing the concentration
dextrose from 5 to 1 or 2%, and increasing the concent
tion of methyl alcohol from 18 to 22%.

For the preparation of a-ethylglucoside the followi
quantities may be employed :—500 grms. of dextro
1947 grms. of 95% ethyl alcohol, 3 litres of macerati
juice, and water to make up 10 litres. The liquid is
until its rotatory power has risen from 5° 18′ to about
The subsequent procedure is similar to that described
a-methylglucoside, but the alcoholic extracts made fr
the dried distillation residue do not deposit crystals
cooling. After being filtered they are evaporated to d
ness and the residue boiled several times with 500
of anhydrous ethyl acetate under a reflux conden
The extracts, filtered hot, and seeded with a trace
a-ethylglucoside, deposit long thin needles of this substa
on cooling. The yield is about 50 grms., and the produ
purified by recrystallisation once or twice from ten ti
its weight of acetone, has $[a]_D = +150 \cdot 9°$ and m.pt. 110
—J. H. L

Cyanogenetic plants of New South Wales. J. M. Pet
Brit. Assoc. (Sect. B.), Australia, 1914. Chem. N
1914, **110**, 126.

OVER a thousand species of plants growing in N
South Wales were examined for hydrocyanic acid
cyanogenetic glucosides. Sixty, including forty-f
species native to New South Wales in seventeen Nat
Orders, gave positive results with sodium picrate pa
Some plants, well known to be cyanophoric in Eur
when grown in N.S.W. never gave any reaction, altho
tested in all seasons. Only a few evolved free hydrocya
acid, naturally, but all showed the presence of a gluco
and enzyme. When the natural enzymes in these pla
were killed by boiling water, the reaction to sodium pic

paper ceased; if then a few drops of emulsin, prepared from sweet almonds, were added, positive reactions were again obtained. Of the sixty species stated, twenty are grasses, and these include eleven species indigenous to N.S.W. The *Sorghum vulgare* examined by Dunstan and Henry lost its glucoside when 11 ins high, but the Australian-grown plant retained it when 4 ft. high and mature. Both glucoside and enzyme slowly disappeared with air-drying. Some species of grasses gave negative results at particular seasons. Two species of grasses alone evolved free hydrocyanic acid, and only one of these is available for grazing. This is the only one, except the sorghums, which has been associated with fatalities among stock. Among the non-cyanogenetic grasses, thirty-three species contained emulsin-like enzymes.

Antipyrine; Determination of ——. Studies in synthetic drug analysis. II. W. O. Emery and S. Palkin. J. Ind. Eng. Chem., 1914, **6**, 751—753 (See also this J., 1914, 887.)

Two methods are described, the first of which is applicable when antipyrine is present alone or in such admixture that after treatment with iodine, no substance other than iodoantipyrine (Bougault, this J., 1900, 269) will be extracted by chloroform. A quantity of the sample containing not more than 0·25 grm. of antipyrine is dissolved in 20 c.c. of water, and treated with 5 c.c. of alcohol-free chloroform, 0·5 grm. of sodium bicarbonate, and a slight excess of iodine (15—20 c.c. of 0·2 *N* solution). After 5 mins., with vigorous agitation at intervals, the free iodine is removed by adding thiosulphate, and the iodoantipyrine extracted by shaking thrice with 25 c.c. of chloroform each time. The chloroform solution is washed with water, filtered, evaporated, and the residue dried for ½ hour at 110° C. and weighed. The weight multiplied by 0·5992 gives the quantity of antipyrine.

The second method can be used when antipyrine is mixed with acetanilide, phenacetin, sulfonal, or other substances which do not give an iodine-derivative insoluble in aqueous acid. The sample (containing not more than 0·25 grm. of antipyrine) is dissolved in 50 c.c. of water, shaken well with 20 c.c. of concentrated hydrochloric acid and 50—60 c.c. of *N*/10 iodine, and after 3 hours, the clear liquid is decanted through a filter of glass wool and asbestos and the tarry precipitate of antipyrine periodide washed 8 or 9 times by decantation with 5% hydrochloric acid, and dissolved in 50 c.c. of methyl alcohol free from ethyl alcohol and acetone. The solution is treated with 5 c.c. of sodium bicarbonate solution and 50 c.c. of water, shaken for 5 mins., whereby the periodide is converted into iodoantipyrine, the excess of iodine removed with thiosulphate and the iodoantipyrine extracted by shaking thrice with 40 c.c. of chloroform each time and determined as described above.—A. S.

Gelonida somnifera, a new hypnotic. H. W. Zahn. Deutsch. med. Wochenschr., 1914, 1273. J. Pharm. Chim., 1914, **10**, 207—208.

The preparation is made in tablets containing 0·01 grm. of codeine phosphate, 0·25 grm. of sodium-veronal and 0·25 grm. of calcium-ervasine (an acetylcresotic acid). —J. H. L.

Saccharin in complex mixtures; Detection and determination of ——. S. Condelli. Staz. sperim. agrar. ital., 1914, **47**, 308. Annali Chim. Appl., 1914, **2**, 47—48.

In the case of solids from 10 to 50 grms. are warmed with a saturated solution of magnesium sulphate and magnesia for about ½ hour at 37°—40° C., the liquid being kept alkaline, if necessary by addition of magnesia. The mixture is allowed to stand, and if the insoluble matter does not separate well, a small quantity of sodium tannate and 96% alcohol may be added. The whole is made up to a known volume with a saturated solution of magnesium sulphate and magnesia, filtered, and an aliquot part of the filtrate made strongly acid with sulphuric acid and extracted three times with a mixture of ether and petroleum ether (b.pt. below 70° C.). The ether extract is filtered, evaporated, the residue dissolved in sulphuric acid and treated with potassium permanganate, and the solution filtered and extracted with freshly distilled ether. The ether extract is allowed to evaporate in a tared dish, the residue of saccharin dried in an exsiccator, weighed, and submitted to known identification tests. Liquids are saturated with magnesium sulphate, warmed to 37°—40° C. for about ½ hour, with addition of sufficient magnesia to give a distinctly alkaline reaction, and then treated as described. If considerable quantities of fatty substances be present, the extraction with a mixture of ether and petroleum ether is preceded by an extraction of the distinctly alkaline solution with petroleum spirit (b.pt. 100°—120° C.).—A. S.

Oils of the Coniferae. I. The leaf and twig oils of Cuban pine (Pinus heterophylla) and longleaf pine (P. palustris) and the cone oil of longleaf pine. A. W. Schorger. J. Ind. Eng. Chem., 1914, **6**, 723—727.

The twigs and needles (leaves) were cut by a machine into lengths of 0·5—1 inch and the green cones were pulped before distillation. The results obtained were:—

—A. S.

Epicamphor; d- and dl ——. R. Furness and W. H. Perkin, jun. Chem. Soc. Trans., 1914, **105**, 2024—2027.

d-Epicamphor was prepared from *l*-camphor by a series of reactions similar to those used for converting *d*-camphor into *l*-epicamphor (this J., 1914, 101), the *l*-camphor being converted, by the action of sodamide and carbon dioxide, into *l*-camphorcarboxylic acid, m. pt. 125°—127° C., and the latter reduced electrolytically by Bredt's method (Annalen, 1906, **348**, 200; 1909, **366**, 1) to a mixture of *l*-borneolcarboxylic acids, from which by the action of acetyl chloride and subsequent distillation, 1-bornylene-3-carboxylic acid was obtained. The subsequent steps were the same as those described previously (*loc. cit.*), except that instead of the method of purification adopted formerly, it was found much more advantageous to convert the crude epicamphor, after distillation in steam, into the semicarbazone by boiling with an equal weight of semicarbazide hydrochloride and of sodium acetate in 70% alcoholic solution for 2 hours. The mixture is allowed to remain overnight in the ice-chest, the crystalline mass separated, washed with ice-cold alcohol until colourless, treated with hydrochloric acid, and pure epicamphor obtained by distilling with steam. The properties of *d*-epicamphor are practically identical with those of *l*-epicamphor except for the reversal of the sign of the optical rotation.—A. S.

Thujone and carone; Action of ammonium hydrosulphide on ——. C. Agostinelli. Gaz. chim. ital., 1914, **44**, II., 111—115.

Thujone when heated with ammonium hydrosulphide in alcoholic solution in a sealed tube, yielded *iso*thujone and a mixture of polysulphides, from the decomposition products of which thio*iso*thujone was isolated. Under similar conditions carone was not isomerised, but yielded a mixture of sulphur-compounds, two of which were probably $(C_{10}H_{17})_2S$ and $C_{40}H_{68}S_5$, respectively, the latter being analogous to the products obtained by Wuyts (this J., 1903, 509) by the action of ammonium sulphide on camphor.—A. S.

Benzoyl in benzoyl derivatives; Determination of ——. A. W. van der Haar. Arch. Pharm., 1914, **252**, 205—208.

The dried benzoyl compound (0·5 grm.) is saponified with alcoholic alkali beneath a reflux condenser, the alcohol evaporated, and the residue acidified with phosphoric acid and shaken with successive portions of ether, until not more than 1 mgrm. is extracted. The united extracts are treated with anhydrous sodium sulphate, and concentrated to a small bulk at a low temperature, the last traces of ether being allowed to evaporate spontaneously. The residue is dried at 40° C. until constant in weight, and then heated at 115° to 120° C. until the weight again becomes constant. The loss in weight gives the amount of benzoic acid volatilised from the benzoyl derivative. The results agree closely with theory in the case of compounds which do not themselves sublime near 115° C. Complete solubility in ether is also essential.—C. A. M.

Sulphonic acids; Reaction of alkali salts of —— *with alkali phenolates* [*phenoxides*] *by dry distillation.* E. H. Nollau and L. C. Daniels. J. Amer. Chem. Soc., 1914, **36**, 1885—1891.

Dry distillation of the alkali salts of sulphonic acids with alkali phenoxides furnishes a convenient method for the preparation of aryl ethers of phenols: $R.SO_3M + R'OM = R'OR + M_2SO_3$, where R represents a phenyl group, or its homologue provided the side chain is not too long, or a methyl group, and R′ a phenyl, or amino-phenyl group. The yields are less than those obtained by the Ullman and Sponagel method with reduced copper (Annalen, 1906, **350**, 83), but the starting materials are in many cases more accessible than the halogen derivatives required in that process. The preparation of a number of aryl ethers by the method is described.—G. F. M.

Ammonium salts of organic acids; Preparation and properties of the ——. *IV.* L. McMaster. J. Amer. Chem. Soc., 1914, **36**, 1916—1925.

Comparison of the properties of normal ammonium salts of organic acids prepared by using ether, alcohol or acetone as media, with the ammonium salts previously described in the literature shows that in many cases the latter were acid salts produced by hydrolysis due to the aqueous medium in which they were prepared. Ammonium palmitate, stearate and oleate were prepared by passing ammonia gas into ethereal solutions of the acids. The precipitates at first gelatinous, tended eventually to become crystalline. The salts were white, and readily lost ammonia when exposed to moist air. Ammonium elaidate was best prepared in an alcoholic medium; it formed white crystalline flakes. Normal ammonium aconitate was obtained from a saturated alcoholic solution of the acid containing a small quantity of ether. It was extremely deliquescent and readily lost ammonia, but its preparation shows that the method is applicable to tribasic acids. Ammonium *o*-, *m*-, and *p*-hydroxybenzoates, and *p*-methoxybenzoate were obtained from solutions of the respective acids in ether or acetone. By the further application of the above general methods the anhydrous normal ammonium salts of hydrocinnamic, hippuric, *o*-toluic, phenyl-acetic, mandelic and uvitic acids were also obtained.—G. F. M.

Mercuric iodide in tablets; Determination of ——. A. W. Bender. J. Ind. Eng. Chem., 1914, **6**, 753—754.

The tablets (containing 1—2 grains HgI_2) are powdered and digested with 20 c.c. of hydrochloric acid (1 : 1) and 0·5 grm. of potassium chlorate under a reflux condenser until the mercuric iodide is dissolved. After diluting to 100 c.c., and removing chlorine by a current of air, the solution is filtered, the insoluble matter washed by decantation, the filtrate treated with excess of ammonia an the mercury precipitated with hydrogen sulphide. Th method can also be used for the determination of mercur in mercury oleate.—A. S.

Condensation and like reactions and method of producin same. H. Hibbert, Wilmington, Del., U.S.A. Eng Pat. 5408, March 3, 1914. Under Int. Conv., Aug. 13 1913.

Iodine is used as condensing agent to effect intramolecula condensation. The reaction may be carried out unde reduced pressure. Mesityl oxide may be obtained almos quantitatively by distilling diacetone-alcohol with abou 0·0001% of its weight of iodine. Similarly pinacone i converted into dimethylbutadiene, using 0·002% iodine, and cyclohexanol into tetrahydrobenzene, usin 0·02% iodine.—T. F. B.

Perfumes in enfleurage with fatty substances; Proce for removing ——. Lautier fils. First Addition, date Jan. 31, 1914, to Fr. Pat. 465,941, Sept. 24, 1913 (se this J., 1914, 613).

The extracted flowers, together with portions of ster dirt, etc., are removed from the perfumed mass aspiration.—T. F. B.

Hydrocarbons and their derivatives; Process for produci ——. Badische Anilin und Soda Fabrik. Fr. Pa 468,427, Feb. 13, 1914. Under Int. Conv., March 1913.

Carbon monoxide or dioxide, or a mixture of the two, made to react with hydrogen or compounds rich hydrogen, such as methane, by passing the gases ov heated catalysts under high pressures. According to t nature of the catalyst and the pressure employed, a varie of products may be obtained, such as liquid hydrocarbon saturated and unsaturated, aldehydes, alcohols, keton and acids. To obtain larger quantities of liquid produ it is better to use gaseous mixtures containing relative small proportions of hydrogen. Metals or metallic oxid (Ce, Co, Mo, Os, Pd) may be used as catalysts, and in son cases their effect may be intensified by adding high basic substances, such as alkali hydroxides. *Example.* mixture of two parts of pure carbon monoxide to one pa of pure hydrogen is passed over asbestos impregnated wi cobalt oxide and a small quantity of caustic soda, heat to 300°—400° C., under a pressure of 100 atmos. deposit of carbon is generally formed, together with wat carbon dioxide, methane, and higher hydrocarbons a their oxygen compounds, which are condensed or absorb in a cooled vessel. The condensed liquid consists of aqueous solution of aldehydes, etc., on which floats an oi liquid containing saturated and unsaturated hydrocarbo of boiling-points up to 250° C. or more. If a gaseo mixture containing nitrogen or sulphur compounds used, compounds containing nitrogen and sulphur formed in some cases. Gaseous mixtures which cont traces of substances which act as "contact poison are purified by passing them over a heated mass of catal before bringing them to the reaction proper.—T. F. B.

Antiseptic substances [*6-halogen-1-methyl-3-hydroxybenz 4-carboxylic acids*]; *Process for making* ——. J. Riedel A.-G. Fr. Pat. 468,949, Feb. 26, 1914. Un Int. Conv., March 19, July 29, and Oct. 23, 1913.

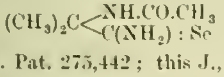
m-Cresotinic acid is converted into its monohalog derivatives, 6-halogen-1-methyl-3-hydroxybenzene-4-c boxylic acids, by treatment with the calcula quantity of halogen in presence of carbon tetrachloride, glacial acetic acid, etc. The preparation of 6-chloro-1-methyl-3-hydroxybenzene-4-carboxylic acid by another method is described in Ger. Pat. 275,093 (this J., 1914, 807). All the above acids are powerful antiseptics. Their soluble salts, as well as those of other derivatives of salicylic acid and its homologues halogenated in the *para*-position to the hydroxyl group, also possess antiseptic properties.—T. F. B.

Anhydrides of organic acids or mixtures of anhydrides with their acids; Process for making ——. R. Muller, and Deutsche Celluloid Fabrik. Fr. Pat. 468,963, Feb. 26, 1914. Under Int. Conv., Dec. 20, 1913.

ACETIC anhydride may be produced in almost theoretical yield by passing the vapours of nitric anhydride or a mixture of nitrogen oxides with air or oxygen over sodium or calcium acetate. If the materials used are not dry, mixtures of acetic anhydride and acetic acid are formed. The anhydride or mixture of anhydride and acid may be separated from the nitrate by heating in a vacuum or by extraction. The product contains only traces of oxides of nitrogen, which are easily separated by distillation over acetates. The reaction can be carried out equally well by passing nitrogen oxides into indifferent liquids containing the acetate in solution or suspension. The same process is applicable to the production of other organic anhydrides.
—T. F. B.

Cyanhydrins of aldehydes or ketones; Process for preparing derivatives of ——. A. Albert. Ger. Pat. 275,847, Aug. 5, 1913. Addition to Ger. Pat. 259,502 (this J., 1913, 673).

IN the process described in Ger. Pat. 273,073 (this J., 1914, 667), the acylated cyanhydrins may be replaced by arylated aminonitriles. For example, α-acetamino-isobutyronitrile is dissolved in alcohol, a small quantity of alcoholic ammonia is added, and the liquid is saturated with hydrogen selenide; a selenamide is obtained of the formula,



$$(CH_3)_2C{<}{\begin{matrix}NH.CO.CH_3\\C(NH_2):Se\end{matrix}}$$

(See also Ger. Pat. 275,442; this J., 1914, 890.)—T. F. B.

Salts of dimethyl-p-amidophenol and p-oxyphenyltrimethylammonium; Manufacture of ——. G. B. Ellis, London. From Chemical Works, formerly Sandoz, Basle, Switzerland. Eng. Pat. 28,736, Dec. 12, 1913.

SEE Fr. Pat. 467,085 of 1914; this J., 1914, 845.—T. F. B.

Arsenostibino compounds and process of making same. P. Ehrlich and P. Karrer, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,108,154, Aug. 25, 1914. Date of appl., July 30, 1913.

SEE Eng. Pat. 17,533 of 1913; this J., 1913, 1030.—T. F. B.

Carbamic acid ester of dichlorhydrin; Process of manufacturing the ——. B. Beckmann, Berlin. U.S. Pat. 1,108,676, Aug. 25, 1914. Date of appl., Nov. 22, 1913.

Erythrene hydrocarbons; Process of manufacturing ——. I. Ostromislensky, Moscow, Russia. U.S. Pat. 1,108,781, Aug. 25, 1914. Date of appl., April 16, 1912.

SEE Fr. Pat. 442,980 of 1912; this J., 1912, 1007.—T. F. B.

Conversion of aliphatic hydrocarbons [of coal distillation gases] into alcohols. Fr. Pat. 468,244. *See* IIA.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic developing agents. Chem. and Drug., 1914, **85**, 413—414.

THERE are no patent-rights existing in connection with the most-used developers, and where these rights formerly existed the claim was for the use in photographic developers of substances well known in organic chemistry.

Pyrogallic acid, or pyrogallol, is prepared by heating gallic acid with two to three times its weight of water in a bronze digester at 200° to 210° C. for about half an hour, a paper ring being placed between the vessel and its cover to allow the carbon dioxide to escape. The resulting solution of pyrogallol is boiled with animal charcoal, filtered, and concentrated. The pyrogallol, crystallising out, is distilled under a pressure of 20 to 30 mm. in order to obtain it perfectly white. (See also Cazeneuve, this J., 1892, 1026). *Pinakol* is a pyrogallol developer containing sodium aminoacetate in place of part of the alkali usually present. *Hydroquinone* (*quinol*).—Aniline (1 part) is dissolved in sulphuric acid (8 parts) and water (30 parts), and a solution of sodium bichromate (2·5 parts) gradually added to the cooled (5° to 10° C.) solution. Potassium sulphite is added to the brown liquid thus obtained, and the whole extracted with ether. The ether is distilled off, the residue dissolved in the smallest possible quantity of hot water, sulphurous acid and animal charcoal added, and the solution boiled and filtered. On standing the quinol separates out from the filtrate. *Adurol* is a haloid substitution-product of quinol, the monochloro-compound being made by passing chlorine through quinol dissolved in benzene. The bromo-derivative is obtained by adding a benzene solution of bromine to one of quinol in the same solvent, evaporating the benzene, and crystallising from ligroin. *Pyrocatechol* (*catechol*) is obtained from beechwood-tar creosote, or by fusing phenol-*o*-sulphonic acid with 24 mol. proportions of caustic potash at 320° to 330° C. (See also Perkin, this J., 1890, 650, and Eng. Pat. 21,853 of 1893; this J., 1894, 879.) *Kachin* is a pyrocatechol developer. *Eikonogen* is the sodium salt of amino-β-naphthol-β-monosulphonic acid. It is prepared from Schaeffer's acid, obtained as a by-product in the aniline-dye industry. (See Meldola, this J., 1889, 958.) *Imogen* is eikonogen modified by the introduction of another amino group. *Diogen* is sodium amino-naphthol-disulphonate. *Para-aminophenol* is photographically of great importance. The following are two methods by which it is prepared: (1) *p*-Nitrophenol (25 kilos.) is added to hydrochloric acid (180 kilos.) at 20° B. (sp. gr. 1·162) and tin (75 kilos.) contained in an earthenware vessel, the temperature rising to 100° to 106° C. Concentrated sulphuric acid (200 kilos.) is next added in a fine stream. After standing for three days the *p*-aminophenol sulphate is filtered off, drained, dissolved in cold water (200 litres), and decomposed with soda, sodium bisulphite (1 kilo.) being added to the solution to protect the precipitated base from oxidation. The precipitate is filter-pressed and dissolved in boiling water (200 to 300 litres) along with sodium bisulphite (10 kilos.), the filtered solution on cooling depositing the base in colourless needles. (2) *p*-Nitrophenol (250 grms.), hydrochloric acid 20° B. (45 grms.), and water (500 c.c.) are heated to 98° C. in an iron vessel provided with an agitator, and iron borings (about 400 grms.) added gradually (15 to 20 grms. at a time) so long as a vigorous reaction takes place. The whole is then boiled for half an hour, and extracted with water (about 2 litres) and sodium carbonate (25 to 30 grms.). The filtered solution deposits *p*-aminophenol on cooling, and the mother-liquor is used for the next extraction, which is continued so long as *p*-aminophenol crystallises out on cooling. (See also Paul, this J., 1897, 63, and Eng. Pat. 5697 of 1897; this J., 1898, 344.) *Rodinol* is the hydrochloride of *p*-aminophenol in concentrated solution. *Unal* is the solid. *Ortol* is methyl-ortho-aminophenol combined with hydroquinone. The starting-point in the manufacture of *o*-aminophenol is *o*-nitrophenol, the ammonium salt being reduced by passing hydrogen sulphide into the solution slowly heated to 40° C. *Metol*, or methyl-*p*-aminophenol sulphate, is obtained by methylating *p*-aminophenol by an indirect method, such as the following: Two mols. of *p*-aminophenol and one mol. of chloroacetic acid in aqueous solution are boiled for about an hour. On cooling *p*-hydroxyglycine crystallises out, which, on melting at 245° to 247° C., decomposes into carbonic acid and metol base, the sulphate of which is the metol of commerce. (See also Paul, this J., 1897, 463, and Lumière and Seyewetz, this J., 1903, 759). *Amidol*, or diaminophenol sulphate, is prepared by reducing ordinary dinitrophenol with tin and hydrochloric acid in a similar way as indicated under *p*-aminophenol. Dinitrophenol is best prepared by warming *p*-nitrophenol with an equal weight of nitric acid (sp. gr. 1·37). (See also Reverdin and de la Harpe, this J., 1892, 157). *Glycin*, or *p*-hydroxyphenylglycocoll, is also prepared from *p*-aminophenol by the action of monochloroacetic acid. *Edinol* is *p*-aminosaligenin hydrochloride, the saligenin being made from salicin. *Diphenal*, or diamino-hydroxydiphenyl, is prepared by a method described in Eng. Pat. 25,136 of 1897 (expired) (see this J., 1898, 1139).

PATENTS.

Photographic printing and paper therefor. W. Willis, Brasted Chart, Kent. Eng. Pat. 20,022, Sept. 4, 1913.

PHOTOGRAPHIC paper which gives an ultimate image composed of silver and platinum, is made by coating paper with an emulsion containing salts of iron, silver, and platinum. It has been found that the reduction of silver chloride by a solution of ferrous oxalate in potassium oxalate is accelerated and rendered more complete in presence of a small quantity of platinic chloride or an alkali platino- or platini-chloride. One method of carrying out the invention consists in coating paper with silver chloride, or with an emulsion containing it, and applying a solution of ferric oxalate containing from 2 to 12 grms. of potassium platinochloride per litre. After exposure to light, the print is developed in a 25% solution of potassium oxalate, passed through a clearing bath containing potassium bisulphate and oxalate, and fixed. Silver bromide may be used in place of silver chloride, and the platinum salt may be added to the developer instead of to the solution used to coat the paper. Especially good results are obtained by using parchmentised paper.
—T. F. B.

Colour photography. P. D. Brewster. Fr. Pat. 468,297, Feb. 10, 1914. Under Int. Conv., Feb. 11, 1913.

IN carrying out this invention, a film or support coated on both sides with sensitive emulsions is used, and the light from the object to be reproduced is brought to the film in such a way that rays of one particular group of colours act on one of the emulsions whilst rays of another group of colours act on the second emulsion. The emulsion on one side of the support is made sensitive to blue and green, for example, whilst the other emulsion is sensitised for red and orange and made relatively non-sensitive to blue and green (*e.g.*, by means of Cyanine). The emulsion on the front of the film may be stained with a colour which absorbs those rays which are not required to act on the other emulsion; the same result is attained by colouring the support of the film. Negatives in colours may be produced on these films by staining the images on either side with different colours. In printing from these colour negatives, further colour-correction may be obtained in the positives by regulating the colour of the light used, *e.g.*, by means of a yellow screen.—T. F. B.

Photographic developer; Preparation and use of a new substance as ——. Union Photographique Industrielle, Etabl. Lumière et Jougla réunis. Fr. Pat. 468,338, April 19, 1913.

IN Fr. Pat. 325,385 (see this J., 1903, 709) is described a compound of methyl-*p*-aminophenol ("metol") with quinol which possesses developing properties and to which the name "metoquinone" was given. It has now been found that chloroquinol forms with methyl-*p*-aminophenol an analogous compound, of m.pt. 100° C., which is more readily soluble in water than "metoquinone," giving solutions which are less easily oxidised by air. It appears to be formed by the combination of two mols. of methyl-*p*-aminophenol with one mol. of chloroquinol. Its photographic developing powers are similar to those of "metoquinone," *viz.*, it can act in aqueous solutions containing alkali sulphite without alkali, whilst if small quantities of alkali carbonates are added to such solutions, the resulting liquids are very stable in air.—T. F. B.

Photographic developers. R. Vidal. Fr. Pat. 468,537, April 26, 1913.

THE products described in Fr. Pat. 391,465 (this J., 1908, 1150) may be used as photographic developers. They are obtained by condensing aromatic amines, hydroxyamines, or their alkyl derivatives with phenols, dihydroxynaphthalenes, hydroxyquinolines, hydroxyanthraquinones, or dihydroxydiphenylamines, especially in presence of hydrocarbons (benzene, etc.). Their activity depends on their constitution; thus, the product from one part of *p*-phenylenediamine and two parts of phenol is a slow developer, and that from three parts of *p*-phenylenediamine and two parts of pyrogallol is a rapid developer.
—T. F. B.

Radiographic plates; Fluorescent —— and process of making them. E. C. Saleil. Fr. Pat. 468,806, May 3, 1913.

PLATES for use in taking photographs by means of Röntgen rays are made by applying to a suitable support a coating of a salt which is phosphorescent under the influence of the rays, and a layer of sensitive silver salt emulsion. The glass or other support is coated with a thin film of gelatin, immersed in acetic acid for a few minutes, and coated with the phosphorescent salt, which may be applied in the form of a liquid made by adding 10 grms. of calcium tungstate and 5 grms. of castor oil to a solution of 4 grms. of nitrocotton in 80 grms. of amyl acetate and 20 grms. of methyl alcohol. When this is dry, the silver salt emulsion is applied. When such plates as these are used, the phosphorescent screen can be dispensed with.
—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Explosives in coal mines. Chem. Trade J., Oct. 3, 1914. [T.R.]

A HOME OFFICE ORDER (No. 1311 of Aug. 29, 1914) adds the following new explosives to the "permitted list":—

Ingredients.	Parts by weight.	
	Not more than	Not less than
Ammonite No. 1 (Miners' Safety Explosive Company, Ltd.):		
Nitrate of ammonium	77	73
Tri-nitro-naphthalene	6	4
Chloride of sodium	21·5	19·5
Moisture	1	0
Super-Ripite (Curtis's and Harvey, Ltd.):		
Nitro-glycerin	53	51
Nitro-cotton	4	2
Nitrate of potassium	15·5	13·5
Borax (dried at 100° C.)	17·5	15·5
Chloride of potassium	9	7
Moisture (total)	8	5

The usual stipulations as to quality, packing, markings, etc. are made in each case.

Patent.

Smokeless powders with a nitrocellulose base; Process of manufacturing ——. P. Joliot. Fr. Pat. 468,337, April 10, 1913.

Nitrocellulose of constant composition (N 12·7%) is prepared by nitrating "regenerated cellulose," *e.g.* from cotton cellulose dissolved in sulpho-carbonic solution (viscose). It is completely soluble in alcohol-ether, and yields a smokeless powder of more constant character than that made from ordinary nitrocellulose.—C. A. M.

XXIII.—ANALYTICAL PROCESSES.

Filtering by suction; Device for freeing a precipitate from mother liquor when ——. R. A. Gortner. J. Amer. Chem. Soc., 1914, **36**, 1967.

A piece of thin sheet rubber fastened over the top of a Büchner funnel by means of a rubber band will prevent the formation of cracks in the precipitate and greatly facilitate the removal of the mother liquor when filtering by suction. The suction draws the rubber down until it presses firmly over the top of the precipitate, and a vacuum of 15 mm. can easily be obtained within the flask.—G. F. M.

Chlorohydrocarbons; Properties of some —— and their use in chemical analysis. II. Determination of the chloroethanes. L. Gowing-Scopes. Analyst., 1914, **39**, 385—388.

The solid compound formed in the reaction between pentachloroethane and phenylhydrazine (this J., 1914, 160) is phenylhydrazine hydrochloride, whilst nitrogen and benzene are also produced. Hexachloroethane and, to a less extent, tetrachloroethane react in the same way. The proportions of hydrochloric acid and nitrogen formed varied with the conditions, which could not be controlled sufficiently to form a basis for a method of determining chloroethanes. The following method was based on the interaction of chloroethanes (except hexachloroethane) and alcoholic alkali to form alkali chloride: Ten c.c. of $N/1$ potassium hydroxide solution in absolute alcohol are introduced into a flask without wetting the neck, 20 c.c. of xylene added, and the flask stoppered and weighed. A few drops (not exceeding 0·15 grm.) of the chloroethane are added, and the flask re-weighed and allowed to stand for a few minutes. Sufficient water to dissolve the precipitated chloride is then added, the liquid acidified with dilute nitric acid, and the chlorine determined with silver nitrate and thiocyanate. One c.c. of $N/10$ silver nitrate corresponds to 0·0168 grm. of tetrachloroethane and 0·0202 grm. of pentachloroethane. The presence of hexachloroethane will cause the results to be low. The reaction does not take place in the cold with di-, tri- or perchloroethylene, chloroform or carbon tetrachloride, but on boiling the solution of a chloroethylene a heavy precipitate is formed. In the case of trichloroethylene the sodium ethoxide reacts with the formation of dichlorovinyl ether. When the solution of hexachloroethane in the xylene alkali solution is allowed to stand for some days or is boiled for some time, the solution becomes deep orange. This reaction is not given by the other chlorohydrocarbons.—C. A. M.

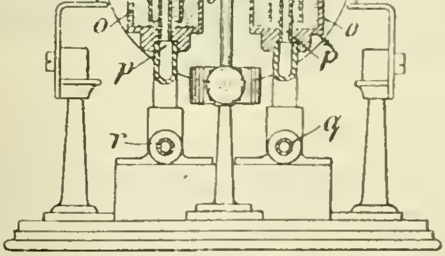
Patent.

Carbon dioxide: Apparatus for estimating the percentage of ——, *in flue gases.* G. Schauli, Cheshunt, Herts. Eng. Pat. 21,542, Sept. 24, 1913.

In a gas balance one end of the beam terminates in a light, hollow sphere, and the other in a pointer, which moves over a scale and is surrounded by a guard.



The method of leading gases into and out of the sphere is as follows: *k* (see fig.) is an inlet, and *l* an outlet, pipe extending, from separate chambers, *m*, below the cross-bar, *e*, attached to the beam, to opposite sides of the sphere, each chamber, *m*, being connected with a bell, *n*, which dips into a mercury-cup, *o*, and covers a vertical pipe, *p*; of the latter, the inlet communicates with a supply pipe, *q*, and the outlet with a delivery pipe, *r*, the air or gas being drawn or forced through the balance by any suitable pumping device. The balance is adjusted to point to zero by a rider on the beam, when the sphere contains pure air; and electrical means are provided for illuminating the scale and for actuating a hooter, when the beam assumes either of the extreme positions.—W. E. F. P.

Trade Report.

Prohibited exports. Order in Council, dated Sept. 25th, 1914, amending previous lists.

The heading "cotton suitable for use in the manufacture of explosives" is deleted from the Proclamation of Aug. 3rd (this J., 1914, 810), and the heading "cotton waste" is expanded to read "cotton waste of all descriptions."

The heading "coal tar products for use in dye manufacture" (Order in Council, Sept. 8th; this J., 1914, 896) is expanded so as to read "coal tar products for use in dye manufacture, except aniline oil and aniline salt."

The exportation of graphite is prohibited to all foreign ports in Europe and on the Mediterranean and Black Seas, other than those of Russia (except Baltic Ports), Belgium, France, Spain, and Portugal.

"Peroxide of manganese" is added to the list of prohibitions of export to all destinations.

Russia; Exportation of prohibited goods from ——. Board of Trade, Oct. 3, 1914.

The export of the following from Russia has been prohibited:—Oilseeds, coal and coke, birch tar (for the manufacture of coal briquettes), iron ore, naphtha and naphtha waste, benzine, kerosine and other illuminating (petroleum) oils and lubricating (petroleum) oils, rubber tyres and rubber, fuses, nitric acid, and saltpetre.

The Russian Government are prepared to authorise without any formality the exportation of these goods in a British or an Allied vessel if the port of destination is a British or Allied port. If, on the other hand, the vessel's port of destination is a neutral port, the Russian Government can only authorise the exportation of prohibited goods by such vessels if the Embassy or Legation of the neutral country in which the port in question is situated certifies in agreement with the Embassy (or Legation) of the Allied country under whose flag the vessel sails that such prohibited goods will be unloaded in a neutral country and will not be re-exported to an enemy country. The Russian Government reserve the right to refuse permission for the exportation of any prohibited goods if such goods are required in Russia. In the case of goods which it is proposed to transport from Russia on neutral vessels, either direct to the United Kingdom or to a neutral port for transhipment to the United Kingdom, application to the Russian authorities for permission to export must be made by the Embassy or Legation of that country under whose flag the vessel sails. Such application will be supported by His Majesty's Embassy at Petrograd at the request of the consignees of the goods in the United Kingdom, provided that such request is addressed to the Embassy through the Foreign Office.

Germany; Prohibition of certain exports from ——. Chem. Trade J., Sept. 26, 1914.

The list of articles which may not be exported from Germany has been modified, and the following have been added to the prohibited list: Acetone, amidosulphonaphtholic acids, aniline, antimony, ether, barium nitrate, gun-cotton, benzidine, benzol, chloroform, dinitrochlorbenzol, dinitrophenol, dinitrotoluol, diphenylamine, ethyl acetate, potassium, sodium, and ammonium nitrates, metallic potassium, lime acetate, natural and synthetic camphor, carbolic acid, colophony, cresol and metacresol, mineral waters, sulphonaphtholic acids, naphthylamine and its sulpho acids, metallic sodium, sodium oxalate, nitraniline, nitrobenzol, phenol, picric acid, phosphorus, juices of fruits and plants (also when prepared with sugar or syrup and when they contain alcohol), nitric acid, sodium sulphide, turpentine oil, toluidine, toluol, trinitrotoluol, metallic wolfram, nitric compounds of cellulose. The prohibition of the exportation of pyrazolone and its products (*e.g.*, pyramidon) and of caustic soda and colour and dyeing materials has been revoked.

Book Received.

L'Industria dei Saponi. Del Dott. V. Scansetti. U. Hoepli, Milan. 1915. Price Lire 5.50.

The volume (6 by 4½ ins.) contains 469 pages of subject matter, with 131 illustrations and also an alphabetical index, the chapter-headings being:—I. Theory of saponification. II. Fats. III. Alkalis. IV. Auxiliary materials for the manufacture of soaps. V. Lyes—their preparation. VI. Apparatus for the manufacture of soap. VII. Hard or soda soaps. VIII. Semi-boiled soaps. IX. Eschweg soap (blue mottled soap). X. Potash or soft soaps. XI. Soaps for industrial use. XII. Toilet soaps. XIII. Extraction of the glycerin. XIV. Analysis of soaps. XV. Cost of production and statistics.

NOTES ON ALCOHOLOMETRY. II.

(Continued from page 856, Vol. XXXII., 1913.)

BY A. F. JOSEPH AND W. N. RAE.
Ceylon Medical College, Colombo.

I.—*Specific gravity of very dilute alcohol solutions.*

In alcoholometric tables, the strengths of dilute solutions appear always to have been obtained by linear interpolation, and no accurate measurements are recorded of the direct determination of the density of very dilute solutions. We have, therefore, carefully determined the density of solutions containing between 0 and 1·7% of alcohol.

The alcohol was prepared by repeatedly boiling Kahlbaum's 99·8% with pure freshly ignited calcium oxide until its density showed it to be practically anhydrous according to the tables of Osborne, McKelvy, and Bearce (this Journal, 1913, 304). As it was only required for preparing very dilute solutions, absolute freedom from water was not necessary, and the sample used, which had a density of 0·77871 at 32·5° C. and corresponding to 99·96% alcohol, was taken as anhydrous.

The mixtures were prepared by weighing about 170 grms. of water in a rubber-stoppered flask on a large Oertling balance, adding the proper quantity of alcohol, and reweighing.

The densities were determined in duplicate and usually by both of us independently. Two thermostats were used, one adjusted to 32·5° C. and the other to 32·57° C.; the results obtained with the use of the latter were reduced to 32·5° C. by means of the coefficients of expansion given by Osborne. Some of the determinations were made in 70 c.c. Bousfield pyknometers and others in ordinary specific gravity bottles provided with a glass cap ground over the outside of the neck. The thermostats were maintained constant to 0·002° C., and error in the densities is probably not greater than one unit in the fifth place of decimals. The following examples are given :—

% alcohol.	Density I.	II.
0·219	0·99447 (A.F.J.)	0·99446 (A.F.J.)
0·661	0·99363 (W.N.R.)	0·99363 (W.N.R.)
1·316	0·99240 (W.N.R.)	0·99239 (A.F.J.)

From the results of 17 duplicate experiments, a large-scale curve was drawn (reading directly to 3 units in the 6th place) and from it the following table has been constructed giving the density of dilute alcohol from 0 to 1·6%.

Alcohol % by weight.	Density (grms. per cc. at 32·5).	Difference for 0·2%
0·0	0·99489	
0·2	0·99451	38
0·4	0·99411	40
0·6	0·99373	38
0·8	0·99337	36
1·0	0·99299	38
1·2	0·99261	38
1·4	0·99224	37
1·6	0·99186	38

There is a slight change of curvature at about 0·7%—this has been confirmed by additional determinations.

The density of a 1% solution calculated from Osborne's table is 0·99301: our result is somewhat lower, but the difference is not large enough to affect ordinary work. Accepting the coefficients of expansion of Osborne, a table can be constructed for any temperature between 10° and 40° C.

II.—*The specific gravity tables contained in the books supplied for use with Sikes' hydrometers.*

At the end of the tables—both the ordinary sets and those of Bedford—is to be found a table ("Table I.") for reducing the readings of the hydrometer to specific gravity. The ordinary tables contain an inaccurate statement to the effect that a gallon of distilled water at 60° F. weighs 10 lb.; this is true at 62° F. (which is correctly given in Bedford's tables) and the specific gravities given in Table I. therefore refer to water at 62° F.

The specific gravity tables in the ordinary and Bedford's books are identical. In order to ascertain the correctness of these tables in a warm atmosphere, we have made determinations of the specific gravity of a few alcohol solutions at 32·5° C. (90·5° F.) and observed the hydrometer reading when the hydrometer jar was immersed in the thermostat. A standard set of glass hydrometers was used throughout.

The density was reduced to 62° F. and compared with that given in the tables :—

Specific gravity at 90·5° F. compared with water at 62° F.

From hydrometer and tables..	0·8345	0·8695	0·9091	0·9230	0·9427	0·9613	0·9810	0·9904
From direct determination ..	0·8344	0·8695	0·9092	0·9228	0·9427	0·9613	0·9810	0·9904]

Since the greatest difference observed could be caused by an error of half a scale division on the glass hydrometer, the Table I. referred to may be taken as correct in a warm atmosphere.

It is advisable that systematic checking should be applied at lower temperatures; we have made attempts to do so at 59° F., but with the room temperature at 82° F. accurate work with the hydrometer is almost impossible, probably owing to convection currents in the hydrometer jar; the following are given as examples of the determinations made :—

Specific gravity at 59° F. compared with water at 62° F.

From hydrometer and tables	0·8436	0·8713	0·9407	0·9674
From direct determination	0·8441	0·8710	0·9407	0·9672

From these and similar results we have tentatively assumed the table correct at all temperatures.

III.—*Comparison of the main hydrometer table with the specific gravity table ("Table I.").*

If we accept Table I. as being correct, it becomes of interest to compare it with the main table (for reducing hydrometer readings to alcoholic strength) in the following manner :—

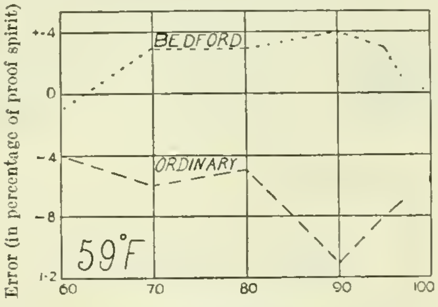
Select some point on the hydrometer scale, say 80, and select a temperature for comparison, say 59° F. (=15° C.).

The alcoholic strength from the ordinary tables is given as 40·2 U.P.=59·8% P.S.

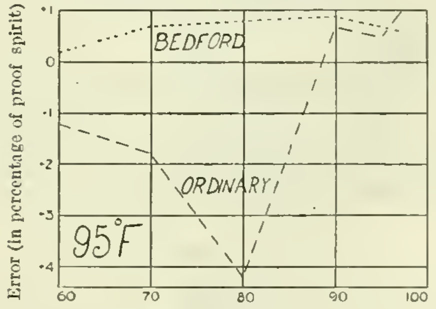
From Table I. the specific gravity is 0·9604 when the hydrometer reading is 80. This, reduced to true density (grams per c.c.), is 0·9593, and from the tables of Osborne, the solution having this density at 15° C. is 28·43% corresponding to 60·3% P.S. There is thus a small inconsistency between the two tables. If the specific gravity table be accepted as correct, then the general table must be wrong. We have calculated similar figures for a number of points on the hydrometer scale at the temperatures 59° F. (15° C.) and 95° F. (35° C.). These are shown in the following table :—

Hydrometer reading.	S.G. from hydrometer table referred to water at 62° F.	Density at 4° C. calculated from S.G.	At 59° F.			At 95° F.		
			True alcoholic strength from O.M. & B.'s tables (in % of proof spirit).	Strength from ordinary tables.	Strength from Bedford's tables.	True strength.	Strength from ordinary tables.	Strength from Bedford's tables.
60	0·9218	0·9207	98·9	98·5	98·8	85·7	84·5	85·9
70	0·9409	0·9398	82·0	81·4	82·3	67·8	66·0	68·5
80	0·9604	0·9593	60·3	59·8	60·6	45·5	41·3	46·3
90	0·9800	0·9789	28·5	27·4	28·9	19·0	19·7	19·9
95	0·9900	0·9889	12·9	12·1	13·2	6·1	6·6	6·8
97	0·9942	0·9931	7·4	6·7	7·5	1·1	2·1	1·7

The errors in the two sets of tables are shown in diagrams in which hydrometer readings are plotted against error expressed as percentages of proof spirit.



Hydrometer readings.



Hydrometer readings.

At these two temperatures Bedford's tables are far more consistent, and more accurate if the specific gravity table be accepted as correct.

Probably the best way of compiling a correct hydrometer table would be first to test thoroughly the correctness of the specific gravity table and then arrange the main table to be consistent with it by the use of the density tables of Osborne.

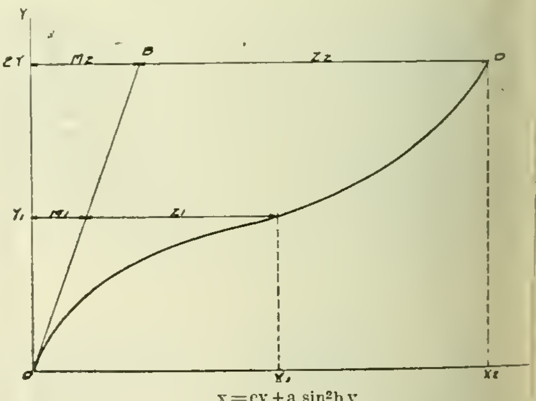
As far as our observations and calculations go, Bedford's tables are to be preferred on the whole, both at high and low temperatures. This was confirmed by a series of tests made on the same solutions of known strength, in Colombo (temperature about 85° F.) and Nuwara Eliya (temperature about 60° F.). At the former temperature, the ordinary tables gave slightly more satisfactory results for weak solutions (80 U.P. and weaker) than those of Bedford. The latter, however, are quite free from the very large errors (several per cent.) which are caused by the use of the ordinary tables for solutions 40 to 60 U.P. As far as we are aware, the errors or inconsistencies in Bedford's tables rarely exceed the error which would be caused by an error of one division in the reading of the hydrometer.

HYSTERESIS TESTS FOR RUBBER.

BY EARLE L. DAVIES.

(*Contribution from the Chemical Laboratory of The Goodyea Tire and Rubber Co., Akron, Ohio, U.S.A.*)

The expert usually judges a piece of rubber by mean of a crude hysteresis test which he performs by stretchin a small strip with his fingers. Experience enables him t judge fairly closely, but by no means accurately, smal differences between two samples; it does not enable hi to standardize his tests, nor to make his results availabl to others. Several machines have been devised to perforn and record these tests graphically, but they have not com into their full usefulness, due to the difficulty encountere in translating the graph into terms which are intelligibl and comparable. The object of this paper is to indicat and explain some of the relationships between the mathe matical equation for the curve and the properties of th rubber being tested, and to point out the close relationshi which some of the tests, which we have made in thi laboratory, show between the theoretical curve and actua curves made by the machine.



$x = cy + a \sin^2 by$

The typical form of curve produced by the machine shown in the figure. The ordinates represent tension an the abscissæ, stretch. Cheneveau and Heim* have shov that this curve has the equation :—

$$x = cy + a \sin_2 by \ldots\ldots\ldots\ldots\ldots($$

and that when OB is drawn tan. to the curve OD at O.

$$c = \tan. \text{ angle } YOB.$$

From equation (1)

$$a \sin^2 by_1 = x_1 - cy_1$$

and since $c = \frac{m_1}{y_1}$ and $z_1 = x_1 - m_1$

we have $z_1 = x_1 - cy_1$

or $z_1 = a \sin^2 by_1 \ldots\ldots\ldots\ldots\ldots$

---

* Sur l'extensibilité du caoutchouc vulcanisé. Comptes Rend Feb. 6th, 1911, p. 320. Also "The Rubber Industry" (1911)

In like manner it may be shown that $z_2 = a \sin^2 2by_1$ .. (3)

where $$y_2 = 2y_1$$

From (2): $$\sin^2 by_1 = \frac{z_1}{a}$$

and since $$2 \sin^2 A = 1 - \cos 2A$$

we have $$\frac{2z_1}{a} = 1 - \cos 2by_1$$

or $$\cos 2by_1 = \frac{a - 2z_1}{a} \quad \ldots\ldots\ldots\ldots\ldots \quad (4)$$

From (3): $$\sin^2 2by_1 = \frac{z_2}{a}$$

(And since $\cos^2 A = 1 - \sin^2 A$)

we have $$\left(\frac{a - 2z_1}{a}\right)^2 = 1 - \frac{z_2}{a}$$

Whence $$a = \frac{4z_1^2}{4z_1 - z_2} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (5)$$

From (2):

$$\cos^2 by_1 = 1 - \frac{z_1}{a}$$

$$= 1 - \frac{z_1(4z_1 - z_2)}{4z_1^2} = \frac{z_2}{4z_1}$$

Whence $$b = \frac{\cos^{-1}\sqrt{\dfrac{z_2}{4z_1}}}{y_1} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (6)$$

That these terms are not so mysterious as they appear, becomes evident after an analysis of the above proof. Thus we find that the constant, c, is dependant solely upon the initial resistance of the rubber to stretching; it will be largest for a pure gum stock and become relatively smaller and smaller as the stock is more heavily compounded. From the relationship in equation 5 we can readily see that in the case of a pure gum stock where the stretch is long and uniform, m_1 and m_2 having been large, a will be relatively large, in comparison with a "tread" stock which will be strong and cause the entire curve to be fairly steep, but will be small in comparison with a "whiting stock," which is characterised by an initial stiffness after which it offers comparatively little resistance to stretching. Equation 6 shows that for pure gum or tread stocks cos b will be small and b consequently large.

The ease with which these values could be standardised in specifications for a given stock is apparent, and the value of such standards both from the point of the manufacturer and the buyer is obvious.

We have done some work in this laboratory to find how closely the curve computed from the equation agrees with the actual curve, of which the following example is typical. For our work we used the "Schwartz Rubber Testing Machine." Test specimens were cut from a "Goodyear" auto inner tube, and from curves drawn in testing these specimens we obtained constants which gave the equation:—

$$x = 1{\cdot}17y + 2{\cdot}06 \sin^2 34{\cdot}6\,y.$$

Another tube made by the same formula was selected at random and a curve drawn from a sample of this tube. Assuming various values for y, the x to correspond was computed from the equation and compared with the same values as measured on the curve.

The results were as follows:—

y	by		x (computed).	x (from curve).	Diff.
inches.	deg.	min.	inches.	inches.	
0·2	6	55	0·26	0·26	0·00
0·5	17	18	0·77	0·78	−0·01
1·0	34	36	1·84	1·86	−0·02
1·5	51	54	3·04	3·05	−0·01
2·0	69	12	4·14	4·08	+0·06
2·5	86	30	4·78	4·70	+0·08
3·0	76	12	5·26	5·17	+0·09
3·5	58	48	5·61	5·60	+0·01
4·0	41	36	5·71	—	—

These are actual measurements from the curve representing only arbitrary values for x and y.

THE METHOD BY WHICH THE CORRECTED SIKES'S TABLES IN USE IN INDIA, FOR DETERMINING THE PROOF-STRENGTHS OF SPIRITS AT TEMPERATURES FROM 40° F. TO 100° F. BY SIKES'S HYDROMETER, WERE CALCULATED.

BY F. G. CARTER.

The Alcohol Tables "for the use of the Appraisers' Department, Calcutta Customs House," issued 1st September, 1889, which were taken originally from The Analyst, Vol. V. (1880, p. 42), were used by me as the basis for the specific gravities of spirits of varying degrees of proof-strengths at 60° F. compared with the sp. gr. of water at 60° F. In these tables the sp. gravity of spirit of proof strength at 60° F. as compared with the sp. gravity of water at 60° F. = 0·9198.

These sp. gravities at 60° F. compared with the sp. gravity of water at 60° F. were then converted into sp. gravities at 60° F. compared with the sp. gravity of water at 62° F. by multiplying by 1·000182 (the expansion of water from 60° F. to 62° F.).

Table B of the Spirits Act of 1880, Ch. 24, pp. 60 2, was then taken as giving the actual sp. gravities of liquids as compared with the sp. gravity of water at 62° F. which Sikes's hydrometers constructed to fit these tables, whether of glass or of brass, should give correctly at 62° F. (the corrected tables were calculated to be used with hydrometers, whether of glass or of brass, which should be constructed to indicate correctly at 62° F. the sp. gravities of Table B. as compared with the sp. gravity of water at 62° F.).

Tables of the expansion of mixtures of water and alcohol in proportions ranging from water to absolute alcohol from 60° F. to 100° F. and contractions from 60° F. to 40° F. were then prepared for calculating variations of temperature for the above (para. 2) sp. gravities, as follows:—

Separate co-ordinate curves were made for 70° F., 85° F., 100° F., 50° F., and 40° F. for expansion throughout the whole range of proof-strengths at these temperatures from the formulæ of Baumhauer,[*] Recknagel, Kopp and others (Castell-Evans's Physico-Chemical Tables, Vol. I) and data derived from these curves were tested against hydrometer determinations of various strengths and at different temperatures compared with pyknometer weighings of the same samples at 60° F. I then completed expansion tables, from which tables of variations of sp. gravities were obtained which agreed generally more nearly, perhaps, with Tralles' Tables, III. and IV.[†] (p. 492 of Bayley's Chemists' Pocket Book) than with the tables by Gilpin and Blagden, by Mendeléeff and others.

After calculating the various sp. gravities as above, for the final step of fitting them at all temperatures from 40° F. to 100° F. to indications, through Table B, of hydrometers (whether of glass or of brass) it was necessary to consider the volume-expansion and volume-contraction of glass and brass from 62° F. to 100° F., and from 62° F.

---

[*] In Baumhauer's coefficients (p. 162 of Castell-Evans, Vol. I.) there is a misprint in the first coefficient of ·033981 for ·031981.

[†] Tralles' Table IV. should read "to be added" where "to be subtracted" is printed and "to be subtracted" where "to be added" is printed.

to 40° F. For this, coefficients of linear expansion for for 1° C. were taken from p. 284 of Deschanel. Part II., Heat, namely, for glass for 1° C. 0·0000081l6, for brass 0.00001878 These were multiplied by 3 for cubical expansion and by $\frac{5}{9}$ to apply them to degrees Fahrenheit.

A table of differences of sp. gravities for each degree of temperature from 40° F. to 100° F. (excepting 62° F.), of which the following is a short summary, was then made, and from this table the necessary adjustments were made before the specific gravities were finally fitted to hydrometer-indications, through Table B.

Having prepared all the preliminary data. on the above lines, the work was then taken in hand systematically.

	To be subtracted.					To be added.						
	40° F.	45° F.	50° F.	55° F.	62° F.	70° F.	75° F.	80° F.	85° F.	90° F.	95° F.	100° F.
For glass instruments	·0003	·00023	·00016	·0001		·0001	·000176	·00024	·0003	·00038	·00045	·00051
For brass do.	·00069	·00053	·000375	·00022		·00025	·0004	·00056	·00072	·00088	·00104	·0012

The following example will perhaps best make clear the above notes and demonstrate the essential system upon which the whole was elaborated.

Proof-spirit at 85° F. and at 50° F.

Data. Sp. gr. $\frac{60^\circ\text{ F.}}{\text{Aq. }60^\circ\text{ F.}} = 0{\cdot}9198$ (" The Analyst," *loc. cit.*).

$\therefore$ Sp. gr. $\frac{60^\circ\text{ F.}}{\text{Aq. }62^\circ\text{ F.}} = 0{\cdot}9198 \times 1{\cdot}000182 = 0{\cdot}919967$

For 85° F.

Expansion of Proof-spirit from 60° F. to 85° F. = 1·0125 approx.

$\therefore$ sp. gr. of $\frac{\text{Proof-spirit}}{\text{Aq. }62^\circ\text{ F.}}$ at 85° F. $= \frac{0{\cdot}919967}{1{\cdot}0125} = 0{\cdot}9086$ nearly.

For expansion of the hydrometer from 62° F. to 85° F.
if for glass instruments *add* 0·0003 to the above,
if for brass instruments *add* 0·0007 to the above.

The hydrometer-indication required, therefore, is that hydrometer-indication in Table B which corresponds,
if for glass instruments, to a sp. gr. of 0·9086 + 0·0003 = 0·9089,
if for brass instruments, to a sp. gr. of 0·9086 + 0·0007 = 0·9093,
that is, for glass hydrometers, an hydrometer-indication = 53·1
and for brass hydrometers, an hydrometer-indication = 53·3

For 50° F.

Contraction of Proof-spirit from 60° F. to 50° F. = 0·99536 approx.

sp. gr. of $\frac{\text{Proof-spirit}}{\text{Aq. }62^\circ\text{ F.}}$ at 50° F. $= \frac{0{\cdot}919967}{0{\cdot}99536} = 0{\cdot}924255$

For contraction of the hydrometer from 62° F. to 50° F.,
if for glass instruments *subtract* 0·00016
if for brass instruments *subtract* 0·000375

The hydrometer-indication required, therefore, is that hydrometer-indication in Table B which corresponds,
if for glass instruments, to a sp. gr. of 0·924255—0·00016 = 0·9241 approx.
if for brass instruments, to a sp. gr. of 0·924255—0·00037 = 0·9239
that is, for glass hydrometers, an hydrometer-indication 61·2
and for brass hydrometers, an hydrometer-indication 61·1

As it had been decided for the future to use glass hydrometers only in India, tables for glass instruments were alone elaborated, but I made a table of proof-degree differences for using or adapting these tables to brass instruments, of which the following is a summary.

NOTE.—Where the + sign is shown these differences are to be added to, and where a — sign to be subtracted from,* net proof-strength found in the tables for glass hydrometers.

Temperatures F.°	40° to 45°	45° to 50°	50° to 55°	55° to 62°	62° to 70°	70° to 75°	75° to 80°	80° to 85°	85° to 90°	90° to 95°	95° to 100°
Differences in sp. gr. between glass and brass	·00034	·00025	·00016	·0007	·00008	·00017	·00026	·00035	·00044	·00053	·00062

A RAPID AND ACCURATE METHOD FOR TH DETERMINATION OF CARBON IN IRON AND ITS ALLOYS.

BY DR. ERNST SZÁSZ, DIÓSGYÖR, HUNGARY.

Recently I described in a German journal (Z. angev Chem., 1913, I., 281) a method for the gas-volumetri determination of carbon in iron by dry combustion, whic was quicker and simpler than the methods hitherto employed, yet gave equally accurate results.

---

* By " net proof-strengths " is meant that *e.g.* 60° u.p. 40° " net proof strength," 25° u.p. is 75° " net proof strength and 40° o.p. is 140° " net proof-strength."

It was based on the following facts and considerations :—If steel turnings be heated in a current of oxygen, very vigorous absorption of the gas occurs at a definite temperature. The flow of gas through the washing bottle connected with the inlet end of the combustion tube becomes much more rapid, whilst that through the washing bottle connected with the outlet end almost ceases. This is frequently referred to as the "suction period." If iron turnings be heated in a combustion apparatus filled with oxygen and a slow current of oxygen passed through the apparatus only after the "suction period" is reached, the oxygen in the apparatus, and that entering at first—so far as it is not utilised in forming carbon dioxide—will all combine with the iron until the latter is completely converted into oxide. The oxygen entering subsequently will serve merely to displace the carbon dioxide and carry it forward, *e.g.*, into a gas-burette, the quantity required for this purpose being less the smaller the size of the combustion apparatus. With a combustion apparatus of suitable dimensions it is possible to work safely with a gas-burette having a bulb of 150 c.c. capacity and a tube with 50 c.c. scale divisions. Care must be taken that during the heating-up period the gases present in the combustion apparatus, which usually contain carbon dioxide long before the suction period is reached (Bauer-Deiss, "*Probenahme u. Analyse von Eisen und Stahl,*" page 124, footnote), do not find their way into the soda-lime tube used for purifying the current of oxygen. This is easily prevented by a trap containing sulphuric acid or mercury. Also, the gas-inlet and outlet tubes must, of course, be as narrow as possible.

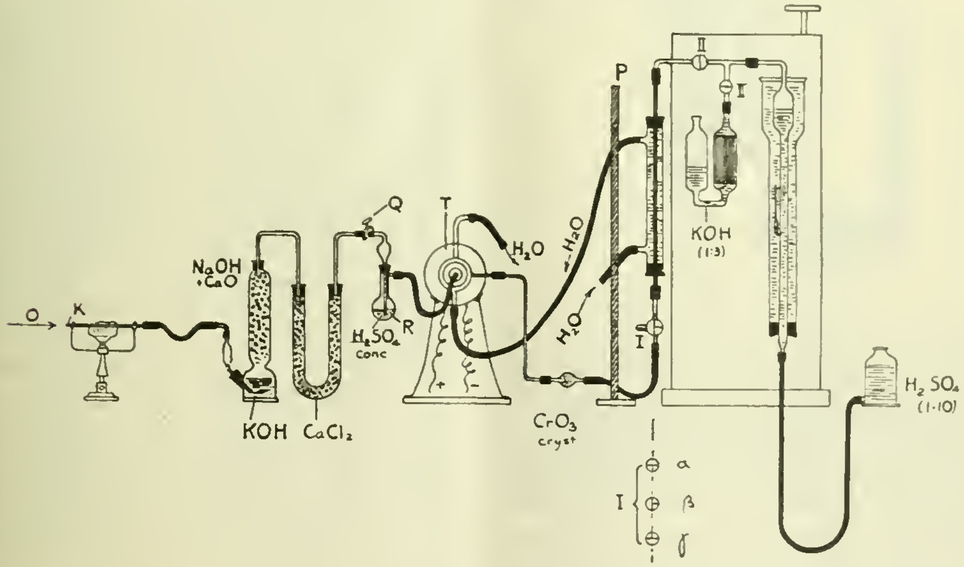

FIG. II.

In the communication referred to above I described an apparatus which was heated by a blast-lamp and in which a platinum container was used for the iron, and mercury as sealing liquid in the gas-burette. I have since been endeavouring to simplify the apparatus, and have succeeded in devising a modified form which should meet all requirements. In this new apparatus the simple electric crucible furnace—the cheapest, and perhaps the most durable, of all types of laboratory furnace—is used. This furnace, already fairly widely employed for other purposes, requires neither an interposed resistance nor a galvanometer, thermo-element and ampère-meter, but may be connected directly with the source of current, and gives the same service as the much more expensive and complicated arrangements hitherto used for steel combustions.

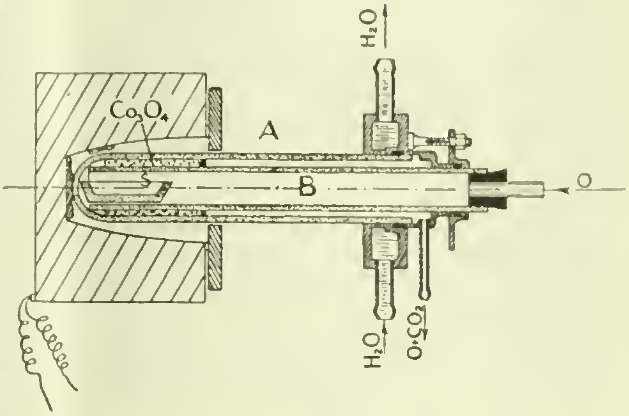

FIG. I.

The combustion apparatus is shown diagrammatically in Fig. I. In the porcelain tube, A, closed at one end, is another porcelain tube, B, open at both ends, the two being connected together by a double stuffing-box of metal. The joint is made tight by two rubber rings protected from heat by a water-cooling arrangement fixed to the stuffing-box. The path of the gas is indicated by arrows. The tubes are glazed only on the outside, and the portion of the annular intermediate space which comes within the furnace, is filled with a mixture of cobalt oxide and fireclay.*

---

* The necessity for an oxygen-carrier in the determination of carbon by combustion has not been definitely established. According to my experience an oxygen-carrier is unnecessary when oxygen is introduced in excess continuously during the suction period (see, for instance, Fleming's procedure, Iron Age, Jan. 2, 1913, 97; Jan. 1, 1914, 64). If, however, no precautions be taken to ensure this, or if—as in the gas-volumetric process—oxygen is not introduced in excess during the suction period, then carbon monoxide may be formed, and the use of an oxygen-carrier is necessary. Cobalt oxide is a suitable material, by reason of its infusibility, but as it easily falls to powder, it is mixed with about an equal volume of fireclay of from 25- to 40-mesh size.

The glazed tube, A, is prevented from adhering to the wall of the furnace by plugs of asbestos pulp. The boat, S, is of suitable capacity for taking 2—2½ grms. of steel turnings.

The whole apparatus is shown diagrammatically in Fig. II. Oxygen passes first through the tube, K, containing platinised asbestos, copper oxide, or the like, and heated by a gas burner or electrically,[*] then through a thick-walled rubber tube, into the combustion apparatus described above, and here, together with the furnace, indicated by T. The combustion gases flow first through a glass capillary, then over solid chromic acid to retain any sulphur dioxide, and through a connecting piece of rubber tubing and a water-cooler, to the gas-burette. A thick metal wire is placed in the water-cooler to increase the cooling action. Dilute sulphuric acid (1 : 10) proved to be the best substitute for mercury as sealing liquid in the gas-burette. The cooling water takes the path indicated in the figure and then flows under the work-bench to feed the gas-holder fixed there.

The gas-holder (see Fig. III.) is arranged to supply a current of oxygen of constant low pressure. The overflow tube, movable up and down, allows of the withdrawal of the gas under any convenient constant pressure. In the present case it is adjusted so that, with the pinch-cock, Q, fully open and the tap, I, in position α, 1—2 bubbles of oxygen per second pass through the sulphuric acid in the trap, R. This is the case when the difference of level marked, Δ, is about 4—5 ins. A steel cylinder, with a reducing valve, might be used, but the gas-holder is simple and quite reliable and possesses advantages in many respects.

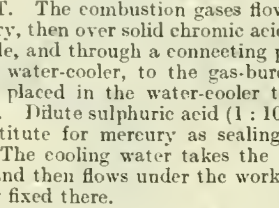

FIG. III.

In the combustion apparatus described, the temperature is, of course, not quite uniform. For example, one hour after turning on the current, I have found repeatedly at the inner end of the tube a temperature of 1070°—1110° C., but about 100° C. lower at the outer end. This fall of temperature is of no consequence in the gravimetric process, for if the soda-lime tube be removed 5—10 mins. after inserting the boat, the results obtained are quite satisfactory. In the gas-volumetric method, on the other hand, the success of the method depends upon attaining complete combustion in a definite, much shorter, period; to effect this the reaction velocity must be accelerated by addition of an oxidising agent. I use a mixture of equal volumes of powdered copper oxide and commercial alumina, well ignited and protected from atmospheric carbon dioxide. Addition of alumina prevents the unnecessarily vigorous reaction which occurs with copper oxide alone, and which would necessitate the premature renewal of the inner tube or cleaning it with acid. If no oxidising agent be added, but the process carried out otherwise exactly as described, the results obtained with steel—according to the composition and thickness of the turnings—are sometimes quite accurate but sometimes as much as 0·04% (or still more with rapid tool steels) too low.[*]

The method of working is as follows :—One hour before beginning a determination, the water supply is turned on, and the furnace connected in the current circuit. After the time mentioned the combustion apparatus has acquired a temperature equilibrium which permits of analyses being carried out successively without interruption. Shortly before proceeding with the test, the whole apparatus is filled up to tap, I, with purified oxygen, and this tap then turned to position γ. The barometric pressure is noted. The pinch-cock, Q, is now tightened somewhat, the rubber stopper withdrawn from the tube, B, and the boat with its contents quickly pushed in until it is in the position shown in Fig. I. The rubber stopper is then immediately replaced, and the pinch-cock, Q, opened fully. The gas-burette is now filled with dilute sulphuric acid, the levelling bottle placed in position, and the tap, I, turned to position, β. After two minutes have elapsed, that is until it is certain that the "suction period" has been attained,[†] the tap, II, is opened, and gas drawn into the measuring burette. The gases should be drawn over for at least 2 mins., the velocity being regulated simply by compressing the tube leading to the levelling bottle. When the current of gas is stopped (by closing the tap, II), the liquid in the burette should be somewhere between the 20 and 50 c.c. marks, according to the carbon content of the sample; the current of gas through R should not cease during this period. The volume of carbon dioxide formed is determined in the known manner by absorption in an Orsat tube (a thrice repeated treatment suffices), and finally the temperature registered by the thermometer in the water-jacket of the gas-burette is noted. The value corresponding to the temperature and barometric pressure taken from Table I, when multiplied by the number of c.c. of carbon dioxide found, gives directly the carbon content in mgrms. The time required for a complete determination, without any haste, is thus: waiting period, 2 mins., withdrawal of gases, 2; three absorptions and 2 readings (allowing ½ min. for the return flow of the sealing liquid), 3; total, 7 mins. The calculation of the result takes but a few seconds. For a carbon content of 0—2%, 1 grm.; 2—4%, 0·5 grm., and 4—8%, 0·25 grm. of sample is taken.

In Table II. results obtained by the chromic-sulphuric acid method (Corleis), by the gravimetric method in a current of oxygen, and by the new gas-volumetric method, are compared. The results are not specially selected, but were obtained partly by me and partly by other workers in my laboratory. In the column relating to the gravimetric method the results marked (A) were obtained when the sample was mixed with lead chromate, bismuth oxide, or copper oxide; those marked (B) by burning the sample either alone or with addition of ferric oxide, alumina, quartz powder, etc.

In carrying out the gas-volumetric process it should be noted that steel can be burnt in the form of tolerably thick turnings; indeed very light, "loose" turnings, which might project from the boat, should be avoided. It is not necessary to mix the turnings and the oxidising agent by shaking together in the weighing bottle; the mixture of copper oxide and alumina may be spread over the turnings in the weighing bottle and the whole distributed fairly uniformly when introduced into the boat. Turnings and oxidising agent should be in the proportion of from 1 : 1 to 1 : 2. Pig irons and iron alloys (including rapid tool steels) are dealt with in a similar manner, but a larger quantity of oxidising agent (corresponding to the capacity of the boat) is used. Only in the case of manganese alloys is it preferable to mix the oxidising agent with the sample by shaking together in the weighing bottle. Moreover these alloys are pulverised more finely the higher their manganese content. In the case of molybdenum steels, in order to fix, as far as possible, the molybdenum trioxide formed, which is troublesome on account of its volatility, the sample is spread over the bottom of the boat and covered with a thick layer of copper oxide (without alumina).

---

[*] The oxygen from steel cylinders occasionally contains considerable quantities of carbon monoxide or hydrocarbons, and to avoid trouble these impurities must be oxidised by passing the oxgyen over incandescent platinum or the like, and the carbon dioxide formed absorbed by soda-lime (see also W. J. Keeler, Iron Age, July 22, 1909, 260).

[*] To ensure complete combustion of 1 grm. of steel turnings without addition of an oxidising agent, in 1—2 mins., an uniform temperature of about 1150° C. over the whole of the boat is necessary. This is attainable, at present, only in large furnaces with costly auxiliary apparatus.

[†] A longer period of waiting though not necessary is not injurious but shortening the period may easily lead to low results. However even with metal of only moderate carbon content, the beginning of combustion may be detected by the *second* return movement of the sulphuric acid in the trap, R.

In Table II. there is no reference to ferrochrome. I have determined the carbon content of this material quite satisfactorily by the gas-volumetric method by using a furnace provided with an interposed resistance and with a pyrometric measuring arrangement. The finely powdered ferrochrome was mixed with twice its weight of fine-steel turnings of known carbon content and placed between two layers of copper oxide in the boat. The furnace was kept at about 1200° C., and after a waiting period of 3 mins., gas was drawn over for a period of 4½—5 mins. Attempts to burn ferrochrome in the crucible furnace as described above, or by a similar procedure, failed, the results being too low. Indeed with the considerably lower and less uniform temperature obtained with the crucible furnace, it is necessary, as experiments showed, to prolong unduly (over 8 mins.) the period during which gas is drawn over, and it is then undoubtedly much simpler to use the gravimetric method, which can be carried out in the usual manner after attaching a drying and purifying train to the tap, 1. One advantage of the costly apparatus previously mentioned, as compared with the crucible furnace, is that it is possible therewith to use the gas-volumetric method with ferrochrome and certain other alloys rarely encountered. Another advantage is that in the combustion of steel, pig iron, etc., no waiting period of 2 mins. is necessary, but one can begin to draw over the gas immediately after introducing the boat into the furnace heated to 1150° C., so that instead of 7 mins., only 5 mins. are required for a determination. A third advantage is that steel can be burnt without addition of an oxidising agent. Against these are the following advantages of the crucible furnace :—(1) The cost of installation and the working expenses are very much less. (2) It requires no supervision (a point of special importance in apparatus installed alongside smelting furnaces for control purposes). (3) The number of porcelain tubes used up is less, as only the inner tube suffers, and this can easily be cleaned (with *aqua regia*) or replaced. (4) Less space is required. (5) It is less liable to injury.

For the gravimetric process the more expensive apparatus offers no advantages.

Both the method and apparatus are patented.

TABLE I.

$$1 \text{ c.c. moist } CO_2 = \frac{1\cdot9768}{(1+\alpha t)} \cdot \frac{(b-w)}{760} \cdot \frac{3}{11} = 0\cdot000709378\,\frac{(b-w)}{(1+\alpha t)} = \frac{\text{Figure in table}}{10\cdot000} \text{ mgr.C.}$$

For room temp. of 10—12, 13—20, 21—29, 30—35° C.
Deduct from barometer reading 1 2 3 4 m/m.

Prizes.

THE IRON AND STEEL INSTITUTE.

Hadfield Research Prize.

A Research Prize of the value of £200 has been placed by Sir Robert A. Hadfield, F.R.S., Past President, at the disposal of the Council of the Iron and Steel Institute, to be awarded by the Council to the author of the best contribution to the publications of the Institute on the subject of the Different Forms or Combinations of Carbon in Iron, Steel, and Alloys of Iron with other Elements. Competition for the Prize is open to metallurgists, chemists and others interested in Metallurgy, and it is proposed that the Prize shall be awarded at the Annual Meeting of the Institute in May, 1916, for the best paper presented before February 1st, 1916. Sir Robert Hadfield is also prepared to offer a second prize for the paper next in merit to the one which gains the first prize provided it is adjudged to be a really meritorious paper.

It is not desired to limit the scope of the research too closely, but it is suggested that the work should be in continuation of, or based upon, the work of previous investigators, such as Jullien, Abel, Müller, Ledebur, T. Sterry Hunt, Akerman, Arnold, E. D. Campbell, Hogg, Parry and others.

The object of the Research Prize is to stimulate the study of carbides in iron and iron alloys generally, also with a view to discovering the best method of determining the forms and combinations in which carbon occurs in iron and steel. These carbides are now spoken of by metallurgists in a general way, as sub-carbides, carbides, or double carbides. It is very desirable to define the composition of these more accuratoly and to ascertain whether other carbides exist which have hitherto not been identified.

The study of the molecular constitution of the carbides will also fall within the range of the investigation and, in this connection, attention may be directed to previous researches on particular combinations of carbon or forms of carbide. For instance, it would be of interest to determine whether the ordinary carbide is Fe_3C, Fe_6C_2, or some other combination. If so, what is its nature and molecular constitution ?

The foregoing is a general direction which should guide intending participants in this research. It is hoped that the results obtained will throw much light on the cause of hardness of steel, also on the nature and form of carbon combinations with iron and its alloys.

Intending competitors should communicate in the first place, with Mr. G. C. Lloyd, Secretary of the Iron and Steel Institute, 28 Victoria Street, London, S.W., from whom further information may be obtained.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows :—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows; Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeoi Paris 3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

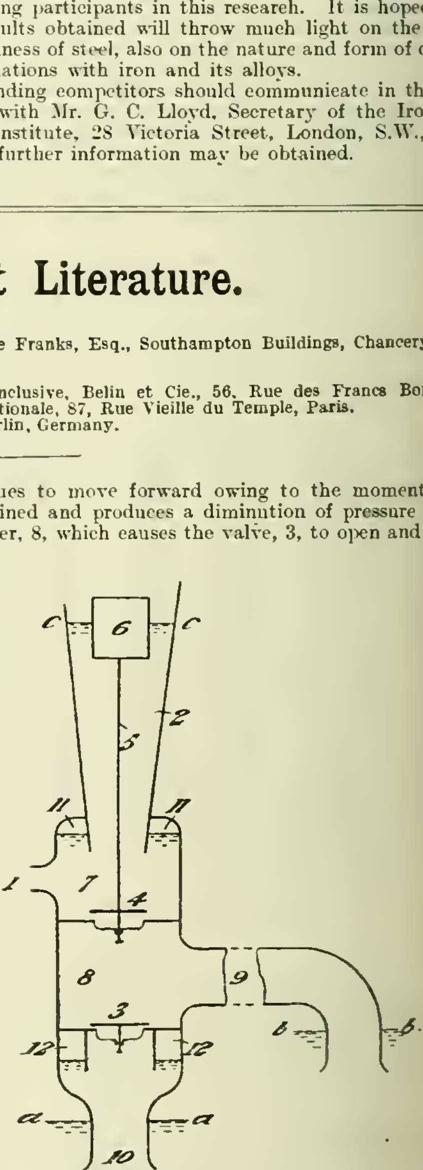
Heat insulation for refrigerating rooms. W. M. Thornton. Engineering, 1914, **98**, 375—376.

Slagwool, cork (built up in half-inch cubes into slabs and heated under pressure until it darkened and formed a coherent mass), granulated cork, and charcoal in small lumps, were investigated. In the first series of tests the material was packed round an electric heater in the middle of a galvanised iron box immersed in a large volume of water. Temperature-equilibrium was reached in 3—5 days, as shown by one thermometer close to the heater and another in the water. The order of conductivity was as given above, the slagwool being the most efficient insulator. In the second series of tests, in which the loss of weight of ice contained in a box jacketed with the material was used to determine its conductivity, the order was changed to cork (slab), slag wool, charcoal. Hence, slagwool is best for high temperatures, as for boilers, and baked cork slabs for rooms the external temperature of which may vary from 0° to 24° C.—O. E. M.

Patents.

Raising or forcing liquids; Methods of and apparatus for ——. H. A. Humphrey, London, and W. J. Rusdell, Wolverhampton. Eng. Pat. 19,169, Aug. 23, 1913.

A liquid under high pressure enters the high-pressure chamber, 7, through the pipe, 1, closes the valve, 4, and rises in the conical reservoir, 2, until it reaches the level, *c*, *c*, when the float, 6, lifts the valve. The high-pressure liquid then enters the chamber, 8, drives forward the liquid in the long main, 9, and delivers some of it into the high-level reservoir at *b*, *b*. The high-pressure liquid flows through the valve, 4, faster than it enters at 1, and consequently the level, *c*, *c*, in the reservoir, 2, falls, allowing the valve, 4, to close. However the liquid in the pipe, 9, continues to move forward owing to the momentum i has gained and produces a diminution of pressure in th chamber, 8, which causes the valve, 3, to open and liqui



from the low-level reservoir, *a*, *a*, enters the chamber, through the pipe, 10, and follows the mass of liquid the long pipe, 9. As soon as the level of the liquid in rises again to the line *c*, *c*, the operation is repeated. The changes of pressure head produced by a "Humphrey" pump may be utilised to supply and control the admission of the high-pressure liquid to the chamber, 8. Air chambers, 11, and 12, are provided to steady the flow. —W. H. C.

Furnaces. A. E. Swan, Derby, and G. W. Parker, Matlock. Eng. Pat. 24,403, Oct. 28, 1913.

Air is led to the rear portion of a furnace through a number of ducts which pass longitudinally through the bridge, terminate at the rear end and are connected with a transverse air-supply channel extending across the front of the bridge.—W. H. C.

Furnaces; Gas-fired ——. C. F. Priest, Normanby, Yorks. Eng. Pat. 25,995, Nov. 13, 1913.

Natural draught coal-fired furnaces are made suitable for direct gas-firing by means of a horizontal elbow-pipe through the ash-pit door opening. The outer end of the pipe has a vertical bracket across it, supporting the end of a steam pipe concentric with the elbow-pipe. Shutters with openings of different sizes may be placed at the outlet of the elbow-pipe to vary the quantity of air introduced and hence the quality of gas produced. The bed of fuel is supported on fire-bars just within and above the ash-pit door. A passage for superheated air for the combustion of the gas is provided in the crown of the producer chamber, the supply of air being controlled by a movable plate at the entrance.—W. F. F.

Automatically controlling the proportionate admixture of two or more liquids; Method and apparatus for ——. B. Bramwell, Belfast. Eng. Pat. 7324, March 23, 1914.

The variation in the difference of pressure produced by variations in the flow of one of the liquids through a Venturi tube is utilised to control the supply of the other liquid. Pipes connected upstream, and with the throat, of the Venturi tube, each deliver liquid into one of two balanced vessels suspended at either end of a cord which passes over a pulley. The vessels have small holes near the bottom so that they never become full and overflow. The oscillation in the levels of these vessels due to the variation in the rate at which the liquid is supplied to them from the two points in the main causes the shaft on which the pulley is arranged to rotate and to wind up or unwind a cord which operates a valve device by which the supply of the other liquid is controlled.—W. H. C.

Tanks; Manufacture of ——. W. Guest, Charlton, Kent, and H. Lenox, Ashtead, Surrey. Eng. Pat. 11,839, May 13. 1914.

To strengthen the construction, rolled channel or U-sections or column sections are interposed between the plates and at the corners of the tank which is built up of plates bolted together, all joints being on the outside. —W. H. C.

Desiccating; Process of ——. C. E. Gray, Eureka, Assignor to A. Jensen, Oakland, Cal. U.S. Pat. 1,107,784, Aug. 18, 1914; date of appl., Nov. 10, 1913.

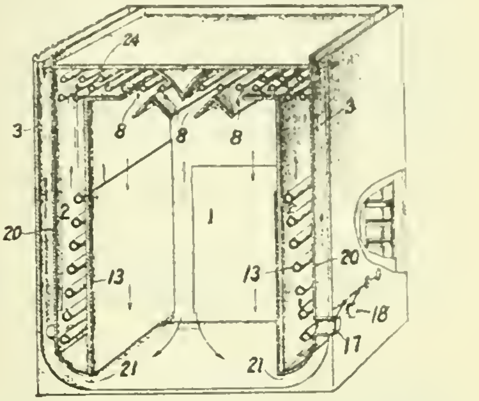
Hot air is blown through a funnel-shaped chamber to form a cyclonic or whirling current travelling inwards towards the axis of the chamber, and the fluid to be dried is admitted through an atomiser in the axis of the chamber so as to travel radially outwards, meeting air of gradually decreasing humidity and increasing temperature.—A. T. L.

Drying machine. W. R. Files, Providence, R.I. U.S. Pat. 1,109,977, Sept. 8, 1914; date of appl., July 14, 1913.

The exhaust steam from a series of steam-heated rotary drying cylinders or "cans" is passed through a separator to remove any entrained liquid and then into a "modifying" "can" or cylinder provided with suitable valves for controlling its temperature.—W. H. C.

Drying-room. C. Hultgren, Chicago, Ill., Assignor to Wenborne-Karpen Dryer Co. U.S. Pat. 1,110,788, Sept. 15, 1914; date of appl., Oct. 21, 1912.

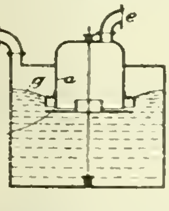
Air enters the inner jacket, 2 (see fig.), through the pipes, 17, 18, which are provided with dampers; passes upwards over the pipes, 13, 24, heated by steam or hot gas, and enters the drying chamber, 1, at the top through the openings, 8. It then passes downwards and escapes from the bottom of the chamber through the passages, 21, into the outer jacket, 3, where it is heated by contact with the metal wall, 20, thus increasing the draught.—W. H. C.



Liquids and gases; Apparatus for scrubbing or similarly treating ——. B. F. B. Sewell, Washington, D.C. U.S. Pat. 1,108,853, Aug. 25, 1914; date of appl., Oct. 21, 1910.

A column for fractionating or for scrubbing gases with liquids, is made up of sections carrying pairs of superposed perforated plates. The perforations are burred and the burrs of one plate of each pair come between those of the other and form a number of liquid seals. A finely perforated plate is submerged in the liquid in order to distribute the vapour bubbles passing through the seals.—A.T.L.

Bringing liquids and gases or vapours into contact with each other; Apparatus for ——. W. Feld, Linz, Germany; K. E. Markel, administrator. U.S. Pat. 1,110,914, Sept. 15, 1914; date of appl., July 18, 1914.



Gas enters the stationary bell, *a*, through the pipe, *e*, and is forced through the liquid, *g*, in an atomised condition by the rotation of the agitator, *d*, which also serves to agitate and mix the liquid. —W. H. C.

Refrigeration; Process of —— *and apparatus therefor.* N. H. Hiller, Carbondale, Pa. U.S. Pat. 1,109,923, Sept. 8, 1914; date of appl., June 15, 1912.

Compressed gas is expanded in a suitable refrigeration plant thereby absorbing heat. Part of the expanded gas is absorbed directly in a liquid and part is compressed to a higher pressure and then absorbed, the liquid being first saturated at the lower pressure and then flowing into another absorber where it is saturated at the higher pressure. The gas is subsequently expelled from the liquid by heating at the higher pressure and passed into the expansion chamber.—W. H. C.

Separator; Centrifugal ——. W. Mauss, Johannesburg. U.S. Pat. 1,111,600, Sept. 22, 1914. Date of appl., Dec. 17, 1912.

See Eng. Pat. 27,113 of 1912; this J., 1913, 702.—T. F. B.

Kiln. C. Hultgren, Assignor to Wenborne-Karpen Dryer Co., Chicago. U.S. Pat. 1,110,787, Sept. 15, 1914. Date of appl., Oct. 30, 1911.

See Eng. Pat. 12,224 of 1912; this J., 1913, 739.—T. F. B.

Furnace and fuel-feeding device therefor. C. J. Greenstreet, Webster Groves, Mo. U.S. Pat. 1,110,926, Sept. 15, 1914. Date of appl., Sept. 26, 1912.

See Eng. Pat. 1515 of 1913; this J., 1914, 635.—T. F. B.

[Vacuum] filter. G. Spence, Mexico. U.S. Pat. 1,111,275 Sept. 22, 1914. Date of appl., Aug. 16, 1913.

See Fr. Pat. 461,346 of 1913; this J., 1914, 187.—T. F. B.

Filter. Eng. Pat. 22,709. *See* XIXa.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coking industry; The by-product ——, and its relation to the manufacture of iron and steel. G. S. Cooper. Iron and Steel Inst., 1914. [Advance proof.] Pp. 31. (See also this J., 1914, 410.)

The Koppers' combination oven (*loc. cit.*) can be operated as a gas oven with blast-furnace gas instead of with producer gas, and by consuming all available blast-furnace gases in this way, a maximum amount of coke-oven gas becomes available in iron and steel works for heating open-hearth furnaces and for other purposes. The coal used for coking should not yield on distillation more than 7—8% H_2O reckoned on the dry coal. The coking character of Scotch coals deteriorates with exposure. The Koppers' process for the direct recovery of ammonia from coke-oven gas has now been applied for the first time to coal gas at the Budapest gas-works. The crude gas is cooled to 25° C., and delivered by an exhauster to the tar extractor. The gas is then reheated to 50°—60° C. and treated with sulphuric acid in a closed saturator from which ammonium sulphate is removed continuously by an ejector working with steam or compressed air. The liquor from the cooler and tar extractor is separated from tar and distilled with lime, the gases being delivered to the hot gas entering the saturator. The gas from the saturators is cooled and scrubbed with creosote oil for the recovery of benzene. The yield of benzene from coke-oven gas varies from 1—1½ galls. in South Wales to 2½—3 galls. per ton of coal carbonised in South Yorkshire, Derbyshire, the Midlands, and Cumberland. In open-hearth steel furnaces the durability of bulkheads and roofs is decreased by 8—10%, and that of the chequer-work increased by 50% by the use of coke-oven gas (see also this J., 1913, 1013). At Friedrich Wilhelmshütte the consumption of coal per ton of steel was reduced from 31·8 to 14·9%.—A. T. L.

Gas retorts; Manufacture of ——. German and English methods. Times Eng. Suppl., Sept. 25, 1914, 109.

While German retorts are hand-made, English manufacturers generally use a machine-press by which the clay is forced through a die of the required section on to a table which descends at the same rate as the ram. Machines of this type turn out 400—500 ft. length of retort per day. Hand-made retorts are built up in sections of about 2 ft. length on a vertical mandril, each section being left for a day or more to dry until it will bear the weight of the next section; or the clay is rammed by means of long-handled spiked punners into a mould consisting of an outer casing and a core. Manufacturing costs are about equal, but the hand-made retorts are more durable. "Segmental" retorts, built up of short lengths with tongued and grooved joints, are more expensive to instal, but last 5 years or more, as compared with about 1200 days for the ordinary moulded retorts. They are more flexible when unequally heated, and leakage at the joints owing to expansion and contraction is soon stopped by scurf. The arch of the retort is made of highly refractory siliceous material, whilst the shoulders and base are of Stourbridge clay which resists erosion by the friction of the coke. The mouth-piece is attached to a short length of moulded retort of Stourbridge clay, which is not injured by liquor falling from the ascension pipe.—A. T. L.

Coal; Absorption of oxygen by ——. T. F. Winmill and J. I. Graham. Times Eng. Suppl., Sept. 25, 114. (See also this J., 1913, 970.)

Coal from the Barnsley beds, dried in a high vacuum over potash and calcium chloride, was sealed up with air in flasks, and the oxygen absorbed was automatically replaced and the amount thus admitted was measured. The total amount of oxygen absorbed was about the same as in the experiments with undried coal in a current of air previously described (*loc. cit.*) but the rate of absorption was slower. Even at low temperatures and with finely powdered coal, oxidation did not cease after 60 days, hence weathering before stacking is not an effective safeguard against spontaneous ignition. Rise of temperature from 30° to 160° C. caused quicker oxidation and an increase in the total oxygen absorbed, especially above 100° C. Rise of temperature was checked by the moisture in the coal, since at 80° C. all the heat generated by oxidation was required to evaporate the moisture, amounting to 5% of the coal. Barnsley Hards and Softs are both capable of firing readily under certain conditions, but these conditions rarely occur in small stacks. In large stacks, evaporation of water may assist the heating, when for example, a narrow "break" fills gradually with coal-dust, and air passing through it becomes charged with water-vapour which heats the coal on which it condenses. This warm coal later comes in contact with air not deprived of its oxygen and the heating is carried further into the "break."—A. T. L.

Tar; Electrical separation of —— from coal gas. A. H White, P. B. Rowley, and C. K. Wirth. J. Gas Lighting, 1914, **127**, 719—721.

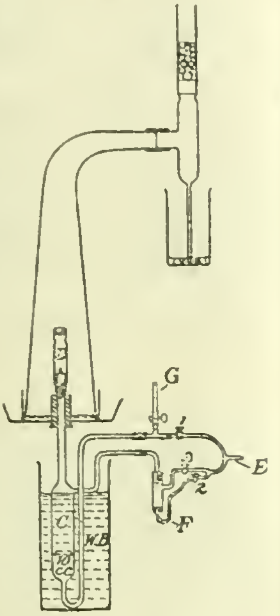
After leaving the Pelouze and Audouin tar separator, the gas was passed at the rate of 24,000 cb. ft. per hour through an inverted U of 8 in. pipe having in the axis of each limb a squirrel-cage electrode of sixteen 27-gauge steel wires strung between 4 in. iron discs 5 ft. 8 in. apart. A potential difference of 20,000 volts was maintained between the electrodes (negative) and the earthed pipes; about 0·2 kilowatt per hour being required. The removal of tar, as shown by filtering 1 cb. ft. of the gas through a 2½ in. circle of filter-paper, was complete. Among the advantages claimed for the method are the possibility of obtaining clean ammonia liquor, and white ammonium sulphate direct from the gas, and greater ease of purification, as tar is prevented from reaching the oxide.—O. E. M.

Flame in mixtures of methane and air; The velocities of —— A. Parker and A. V. Rhead. Chem. Soc. Trans., 1914, **105**, 2150—2158.

In connection with the study of fire-damp explosions in mines, the authors determined the velocity of flame propagation in mixtures of pure methane and air in straight horizontal tubes of glass, lead, copper and iron, 6·5 m. long and about 2·5 cm. diam. The tubes were closed at one end and the gas was ignited at the open end by a spark. The progress of the flame was recorded electrically by the fusing of thin strips of Wood's alloy arranged 1 m. apart in the tubes. The flame travelled at a constant velocity for about 4 m., then oscillated with increased velocity of propagation, and finally attained a constant velocity towards the end of the tube. The initial velocity varied with the strength of the mixture and with the material of the tube, being least with tubes having a high conductivity for heat. The maximum initial velocity was 70 cm. per sec. with a mixture containing CH_4 10%. The limits of inflammability occurred with CH_4 4·5 and 13·1% respectively.—A. T. L.

Sulphur in motor spirits; Determination of ——. W. A. Bradbury and F. Owen. Chem. News, 1914, **110**, 163—165.

When a mixture of carbon bisulphide or benzene with methylated spirit was burned in a wick lamp and the sulphur dioxide in the products absorbed as in the Referee apparatus for determining sulphur in coal gas, low results were obtained owing to incomplete combustion, the deficiency varying from 4 to 50% of the total sulphur. With the apparatus shown in the figure, the deficiency was only about 6·6%. The wick-burner was replaced by a carburettor, C, containing 10 c.c. of the benzene or petrol to be tested and the mixture from the carburettor passed to an atmospheric burner, D, in the trumpet tube of a Referee apparatus, the lower end of the trumpet tube being sealed in water. The sulphur dioxide was absorbed with perhydrol (a concentrated solution of hydrogen peroxide). At the commencement of a determination, taps, 1, 2, and 3, are closed, a water-blower started to deliver air at E, and the perhydrol solution allowed to flow down the absorption column. Tap, 2, is then opened, allowing air to bubble through pure benzene or petrol in tube, F, and tap, 3, is adjusted until the burner gives a perfect Bunsen flame with a maximum brightness of the platinum spiral which is arranged above the burner. The trumpet tube is then placed in position and tap, 1, opened and 2 closed so as to burn the spirit which is under test. When half the spirit has been consumed, the water-bath is heated to 150°—160° F. (65·5°—71° C.). Towards the end, turpentine is run into the carburettor at G, and this operation is repeated so as to burn all the spirit originally in C.—A. T. L



Report of Committee of American Society for Testing Materials on standard tests for lubricants. *See* XII.

Patents.

Peat; Impts. in the treatment and utilisation of ——. J. W. Leadbeater. Doncaster. Eng. Pat. 29,281, Dec. 19, 1913. Addition to Eng. Pat. 18,587, Aug. 13, 1912.

To produce a hard coke suitable for steel-smelting, 5—10% of coke obtained from bituminous coal is added to a mixture of the pure "carbon coke" and the special tar produced from peat as described in the prior patent (this J., 1913, 820). The mixture is compressed into blocks, and heated in a retort.—W. F. F.

Combustible mixtures; Surface combustion of ——. P. St. G. Kirke, and Bonecourt Surface Combustion, Ltd., London. Eng. Pat. 20,476, Sept. 10, 1913.

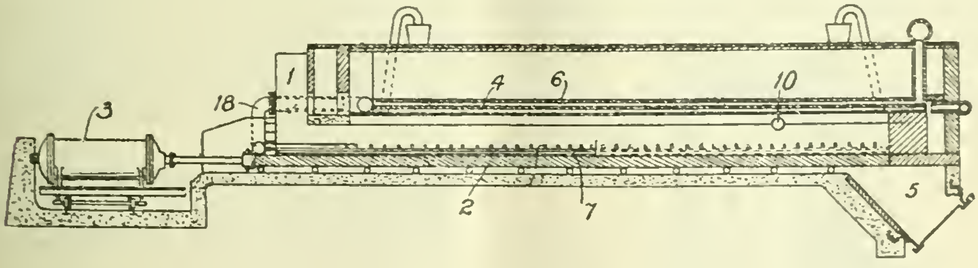
The mixture of fuel and air is introduced into the combustion bed in the manner described in Eng. Pats. 25,808 and 29,430 of 1909 and 19,490 of 1912 (this J., 1910, 1448; 1913, 936). To avoid intense local heating and consequent disintegration of the refractory material at the points of impact near the inlet, the combustion bed may be formed by a layer of refractory blocks at the base of the heating furnace, arranged so as to leave a network of channels open at the top. The gas inlet is in a line with one of these channels so that no immediate impact takes place, and the bed may be loosely covered with granular refractory material. In another form (*e.g.* a bath enamelling furnace), the heating ducts may be arranged on the internal surface of a cylinder and in another form the combustion surface may be within the body to be heated.—W. F. F.

Combustion; Process of regulating the temperature of ——. J. M. Rusby and J. H. Taussig, Assignors to United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,110,991, Sept. 15, 1914; date of appl., Dec. 27, 1909.

A burning mixture of producer gas and air is diluted by the incombustible products of combustion.—W. F. F.

Coking process. J. P. O'Donnell, London. From L. L. Summers, Chicago, Ill. Eng. Pat. 2069, Jan. 26, 1914.

The retort, which is particularly adapted for coal rich in volatile matter, has a reciprocating floor, 2, actuated by a ram, 3, fuel being fed from the bin, 1, and discharged into the hopper, 5. The retort is heated by hot gases which pass through the passages, 4, in the crown. Retort gases pass by the duct, 10, to a recuperator and condenser, and thence through the ducts, 6, in the retort crown, and pipe, 18, to the nozzles, 7. These hot gases thus pass upwards through that portion of the fuel which is between the fresh charge and the highly heated part. A more uniform heating is obtained, which results in a maximum amount of rich hydrocarbons and tar, while the fuel assumes a plastic condition and is compressed by the reciprocation of the floor, 2, being discharged as a hard dense coke.—W. F. F.



Coke dust; Process for making briquettes of —— *by means of cement and pitch, for use in gas manufacture.* Deutsch-Luxemburgische Bergwerks- u. Hütten-A.-G. Ger. Pat 275,511, July 31, 1913.

Briquettes made from coke dust with cement alone require some time to harden, and therefore must be stored in the works. To avoid this it is proposed to add a quantity of pitch so small that the impurities in the gas, made from the briquettes, can be eliminated in the ordinary purifying process. The following proportions are given: Coke, 85%; cement, 12%; coal tar pitch, 3%.—T. F. B.

(a) *Carbon monoxide, hydrogen and nitrogen,* (b) *carbon monoxide and hydrogen; Process of making* ——. R. H. Brownlee and R. H. Uhlinger, Assignors to American Nitro-Products Co., Pittsburgh, Pa. U.S. Pats. 1,107,581, and 1,107,582, Aug. 18, 1914; date of appl., April 12, 1913.

(a) Carbonaceous fuel together with insufficient air for complete combustion, is drawn periodically into a cylinder fitted with a reciprocating piston, the mixture is exploded, and the products are exhausted and passed through apparatus for separating the carbon monoxide, hydrogen and nitrogen from one another and from the other products of combustion. (b) Oxygen is used instead of air, and carbon dioxide and monoxide, and hydrogen are separated from the combustion products. —A. T. L

Ethane: Process of manufacturing ——. S. P. Mulliken, Newburyport, Mass., and H. K. Moore, Berlin, N.H. U.S. Pat. 1,107,696, Aug. 18, 1914; date of appl., Dec. 8, 1910.

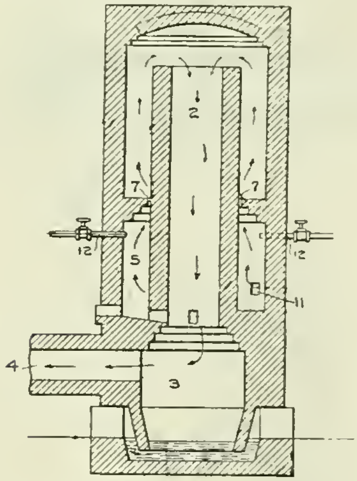
Ethylene is reduced to ethane by hydrogen in the presence of a catalyser which is cooled in order to remove the heat generated by the reaction.—A. T. L.

Gas-producer. T. B. Benner, Cortland, N.Y. U.S. Pat. 1,110,372, Sept. 15, 1914; date of appl., March 21, 1914.

The producer comprises two superposed retorts communicating with each other and with a fuel-charging hopper by co-axial ports. Gas-receiving chambers at the end of each retort are in communication with each other, and a pipe leads from the upper chamber into a hydraulic main.—W. F. F.

Gas; Process of making ——. J. H. Hirt, El Paso, Tex., Assignor to Allis-Chalmers Manufacturing Co. U.S. Pat. 1,110,782, Sept. 15, 1914; date of appl., Feb. 14, 1910.

An ignited mixture of fuel and air is injected from the conduit, 11, into the annular chamber, 5, with an upward spiral motion, and is caused to contract at the point, 7. The mixture is cooled at this point by introducing an endothermic agent (moisture) by pipe, 12, and then passes by the central passage, 2, and water-sealed chamber, 3, to the outlet, 4.—W. F. F.



Scrubbers for gases. A. Hollis, Stockton-on-Tees. Eng. Pat. 2609, Jan. 31, 1914.

The scrubber, suitable for purifying producer-gas, consists of a number of perforated shelves packed with sawdust or similar material, one shelf near the top being in the form of a tray with openings covered by hoods. Liquid collects on the tray, thus avoiding fouling of the lower layers through which the gas afterwards passes. —W. F. F.

Natural gas; Process of separating the hydrocarbons contained in ——. H. Koppers, Assignor to H. Koppers Co., Chicago, Ill. U.S. Pat. 1,107,803, Aug. 18, 1914; date of appl., July 8, 1913.

The gas is passed under pressure through a solvent oil in a cast-iron bell-washer which is relieved of pressure by placing it within a wrought iron casing through which the gas passes.—A. T. L.

Explosive-engines; Method for economizing fuel and preventing carbon deposits in ——. C. L. Nedoma, Assignor to J. H. Fletcher, San Francisco, Cal. U.S. Pat. 1,108,608, Aug. 25, 1914; date of appl., Sept. 2, 1913.

The vaporised hydrocarbon fuel is mixed with oxygen and steam obtained by heating hydrogen peroxide. —A. T. L.

Petroleum and its by-products; Refining ——. E. A. Starke, Berkeley, Cal. U.S. Pat. 1,109,187, Sept. 1, 1914; date of appl., May 25, 1911.

Petroleum or a distillate thereof containing benzene derivatives is saturated with sulphur dioxide, and agitated, whilst hot, with sulphuric acid in a closed vessel, until the specific gravity is constant. The sulphur dioxide generated from the acid is not allowed to escape from the vessel. The liquid is allowed to stand, and the separated sulphonic acids drawn off and treated for the recovery of "benzene." —A. T. L.

Petroleum; Apparatus for refining ——. M. H. Warren, Mexico. U.S. Pat. 1,110,361, Sept. 15, 1914; date of appl., Nov. 17, 1913.

The petroleum is passed through a series of heat-exchanging apparatus to stills containing horizontal baffles providing a tortuous path for the flow of a thin stream of oil. Superheated steam is admitted to the stills and the light and heavy vapours are led away separately to condensers. —A. T. L.

Lubricant grease. F. E. Mariner, Assignor to The Pensacola Tar and Turpentine Co., Gull Point, Fla. U.S. Pat. 1,109,298, Sept. 1, 1914; date of appl., Oct. 2, 1913.

A mixture of mineral oil, 90, rosin (containing more than 60% of abietic acid) 8, and milk of lime 20 parts.—A. T. L.

Hydrocarbon oils: Process of treating heavy ——. C. J. Greenstreet, Denver, Colo. U.S. Pats. (a) 1,110,923 and (b) 1,110,924, Sept. 15, 1914; dates of appl., Mar 13, 1911, and May 13, 1912.

(a) Oil vapour mixed with steam is passed through a pip coil heated above 1000° F. (538° C.) and the proportion are adjusted so that the product burns at a test-burne with a bluish flame. The product is then fractionall condensed in order to obtain light oils. (b) An unobstructed coil of pipe, 100 ft. long and $1\frac{1}{2}$ in. diam., is used and oil at a pressure of 50 lb. per sq. in. is injected into th coil under a steam pressure of 100 lb. per sq. in.—A. T. L

Olefines and their oxidation products [from mineral oils] Process of manufacturing ——. C. J. Greenstreet Webster Groves, Mo. U.S. Pat. 1,110,925. Sept. 1 1914; date of appl., June 7, 1912.

Mineral oil mixed with steam is passed repeatedly throug a long coil of pipe at cherry-red heat, the olefines forme are oxidised and the product separated by fractiona distillation.—A. T. L.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood distillation works, Forest of Dean. Reprinted from [Cd. 7488]. Price 3d.

These works have been erected with the object of utilising the considerable quantities of almost unmarketable cord-wood and small branch-wood which are left over when the broadleaved trees in Dean Forest and the adjoining woodlands are felled. The works were opened in October, 1913.

The total capital cost was approximately as follows:—Buildings, £8000; machinery, £6500; fittings, architect's commission, fencing, etc., £1000; total, £15,500.

The process of F. H. Meyer, of Hannover-Hainholz, was adopted, and the machinery was designed and supplied by his firm, the engine, boiler, and principal non-patented apparatus being of English manufacture. The buildings were erected from Meyer's plans. The works are designed to produce charcoal, wood tar, wood alcohol, and grey acetate of lime. It is not intended at present to manufacture acetone, but the works have been designed for installing the additional machinery necessary for that purpose, if required.

The contractor estimated that the following products would be obtained from the plant by carbonising 420,000 cubic feet of wood per annum:—Grey acetate of lime, 384 tons; tar, 270 tons; charcoal, 1380 tons; wood spirit, 90 tons (equal to 23,400 gallons of 8·61 lb. each). As production commenced only a few months ago, it is not possible to compare fully the results and estimates, but the experience already gained leads to the conclusion that the above output will scarcely be obtained.

Most of the wood used is oak, which is brought in by hauliers from the Crown forests, in the centre of which the works are situated, and is stored in large stacks, a stock of 1500 to 2000 cords being kept at the works.

The retort for the carbonisation of the wood is built of iron plate and is about 56 feet in length and 7½ feet in diameter. It is fired from a furnace on the left side, and is set in flues which enable the wood to be carbonised effectually. The wood is packed into cylindrical trucks, each holding about two cords, or 256 cubic feet, stacked, and five trucks form one charge for the retort. When ready the iron door of the retort is lifted and the trucks of wood are drawn in by an electric motor. The door is then closed and the temperature raised to between 330 and 350° C. Distillation usually commences in about two hours and continues for twenty to twenty-two hours.

After the process is completed the door at the other end of the retort is raised, and the trucks, which now contain charcoal, are quickly drawn by motor into an iron cooling-chamber similar in form to the retort. The doors at each end of the cooling-chamber are made secure and the exterior is cooled with water. From the cooler the trucks of charcoal are removed, on the following day, to the charcoal shed, where they are emptied and the charcoal filled into bags ready for despatch.

During the process of distillation about 70% of the weight of the wood is gasified: the gases pass out of the top of the retort through two copper pipes into a tar separator, where the tar is condensed and flows into a tank. The tar is then run into a *montejus* and lifted by a compressor into the tar still, where it is freed from the acid, oils, and water. It is run direct from the still into casks, and is then ready for marketing. The gases and vapours, freed from tar, pass out at the top of the separator, and on into a tubular condenser, where the naphtha and acid vapours are condensed and run into large storage vats. This pyroligneous liquor is left in the vat three or four days to free it from any tar in suspension, and is then ready for further treatment. The incondensible gases pass from the tubular condenser into a washer, where any residual naphtha or acid is removed by water, and are then conveyed by a pipe to the furnace, where they are utilised in the process of carbonisation.

The pyroligneous liquor, freed from tar, is pumped from the storage tanks to a vat in the acid room and neutralised with lime, the liquor being stirred continuously by a mechanical stirrer until the mixing and neutralisation are complete. Thence it is pumped into settling tanks at the top of the building, then into sludge tanks on the first floor, where further impurities are removed, and thence into a storage tank in the acid room.

It is now pumped into a small "clear liquor" tank on the top floor, and runs thence into the iron column of the continuous apparatus, where the neutralised acid liquor is completely separated from the naphtha. This apparatus consists of a wrought-iron base or still, containing a copper coil, surmounted by a series of cast-iron plates. The neutralised liquor is run off continuously from the still into a tank below, and while still hot is pumped into an evaporating pan. It is there boiled down to a strength of about 10° B. (sp. gr. 1·075), and then run into the pan of a rotary dryer. This is a large wrought-iron drum, heated internally with live steam. The drum revolves slowly in a shallow tank and picks up a coating of the neutralised liquor. The liquor is dried, as the drum revolves, to a content of about 70% of grey acetate of lime, and then removed by a series of scrapers on the other side. The acetate, which is now in a pasty condition, is spread upon a concrete drying floor, under which pass the gases from the retort to the chimney stack, and, after being dried for several hours, is filled into sacks. The acetate now contains from 84 to 85% of true acetate of lime.

The naphtha which runs from the top of the iron still and column, after being freed from the acetate of lime liquor as previously described and also from some of the heavy oils, is passed through a copper wash-column, into which a weak solution of sulphuric acid trickles, and is here further purified. Thence it goes into a second column, where it is treated with a weak solution of caustic soda, and more oils are separated out. After passing through a small condenser the purified methyl alcohol is run into a storage tank below, and is ready for filling into drums for despatch.

Power is provided by a 27 ft. by 7 ft. 6 ins. boiler, which supplies steam to the following machines:—a 35 H.P. single-cylinder, non-condensing engine; a steam pump for the cooling water; the fan engine; the condenser engine; the evaporating pan; the rotary dryer; the continuous apparatus; the tar still; the tar condenser; and the boiler-feed pump.

The main engine drives a dynamo, which, in addition to lighting the works, provides power for the motors used in charging and discharging the retort and cooler, and for the acid pump, the neutralised liquor pump, the clear liquor pump, the evaporator pump, the lime stirrer, and the rotary dryer.

Patents.

Peat or the like: Treatment of wet-carbonised ——. T. Rigby, Dumfries, and Wetcarbonizing Ltd. London. Eng. Pat. 17,773, Aug. 2, 1913.

Peat pulp resulting from the wet-carbonising process (see Eng. Pat. 17 610 of 1911 and 25,146 of 1912; this J., 1912, 1171; 1914, 346) is partially dehydrated by treatment in a very thin layer on a continuous band or rotary filter, filtration being effected either by a partial vacuum or by pressure produced by the gases from the wetcarbonising process. The moisture is reduced from 94 to 75% by this treatment, and the product is further dehydrated in a band press or other suitable manner. (See Eng. Pats. 4684 and 24,748 of 1911; this J., 1912, 323; 1913, 77)

—W. H. C.

Wood; Destructive distillation of ——. S. E. Seaman, Brooklyn, N.Y. U.S. Pat. 1,108,403, Aug. 25, 1914; date of appl., Dec. 27, 1913.

Sawdust is carbonised in a closed retort, and the cooled tar-free gas obtained in the distillation is forced through the fresh sawdust in a closed vessel to remove air from the charge before it enters the retort. The resulting mixture of air and gases is burned beneath the retort.

—A. T. L.

Carbonaceous material; Process for treating ——. C. W. Tozer, London. Eng. Pat. 7117, March 20, 1914.

Coal or other carbonaceous material is heated in retorts at 300°—700° C. and under an absolute pressure of 4·9 to 12·25 lb. per sq. in. (*i.e.*, a vacuum of 20 to 5 in. of mercury). More efficient recovery of by-products and the production of smokeless fuel, which is easily ignited, are the advantages claimed for this process.—T. F. B.

[*Wood*] *Distillation; Process of* ——. T. W. Pritchard, Wilmington, N.C., and M. C. Whitaker, New York. U.S. Pat. 1,110,820, Sept. 15, 1914; date of appl., Nov. 12, 1912.

Wood or other solid material is introduced into an externally-heated retort in containers which leave a free space between the charge and the retort walls. The vapours from the retort are drawn off by an exhauster, cooled, and the uncondensed portion reheated by the flue gases and circulated again through the retort in order to equalise the heating throughout the charge.—A. T. L.

[*Wood*] *Distillation; Process of* ——. M. C. Whitaker, New York. U.S. Pat. 1,110,850, Sept. 15, 1914; date of appl., Nov. 12, 1912.

The vapours from the retort (see preceding abstract) are drawn by a fan through a passage beneath the floor of the retort and delivered again to the space above the charge without condensation.—A. T. L.

Lamps; Electric incandescent ——. G. M. J. Mackay, Schenectady, N.Y., U.S.A. Eng. Pat. 1252, Jan. 16, 1914. Under Int. Conv., Sept. 8, 1913.

To prevent blackening of the bulb of metal (*e.g.*, tungsten) filament lamps, a small quantity of an oxide of phosphorus, preferably P_2O_5, is placed in the lamp.—W. F. F.

Lamps; Manufacture of electric filament ——. C. A. von Welsbach, Vienna, Assignor to Welsbach Light Co., Gloucester City, N.J. U.S. Pat. 1,109,886, Sept. 8, 1914; date of appl., Aug. 9, 1898.

Successive coatings containing osmium, are applied to a wire, *e.g.*, platinum, which is heated after the application of each coating. The core is finally volatilised by passing a gradually increasing current through the wire in an atmosphere which oxidises any carbon in the coating. —W. F. F.

Vacuum [*in electric lamp bulbs*]; *Means for improving a* ——. M. von Recklinghausen, Suresnes, France, Assignor to Cooper Hewitt Electric Co., Hoboken, N.J. U.S. Pat. 1,110,576, Sept. 15, 1914; date of appl., July 29, 1913.

An arc is temporarily formed in the bulb between electrodes, one of which is of boron. The residual gases are absorbed by the heated boron.—W. F. F.

Electric filaments; Manufacture of ——. C. Auer von Welsbach, Vienna. U.S. Pats. 1,109,887 and 1,109,888, Sept. 8, 1914. Dates of appl., Aug. 24, 1899.

See Eng. Pat. 13,116 of 1898; this J., 1899, 571.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Patents.

Coal tar or its products; Treatment of —— for the removal of the properties therein tending to induce pitch cancer. H. W. Robinson, Sedgley, Stafford. Eng. Pat. 20,767, Sept. 15, 1913.

The "auxetic" properties can be removed from coal tar or its products by treatment with ozonised air; the process is not carried further than is necessary for the specific purpose, so that practically the normal distillation products are obtained by the usual method. The ozonised air may be applied at a pressure of 20 to 30 lb. per sq inch for 60 to 90 minutes. (See also Eng. Pat. 4159 of 1913; this J., 1914, 412.)—T. F. B.

Carbon: Manufacture of ——. Soc. Anon. des Combustibles Industriels, Haine-St.-Paul, Belgium. Eng. Pat. 6354, March 12, 1914. Under Int. Conv., July 24, 1913.

Hydrocarbons such as coal tar or tar oils, petroleum tar or tar oils, are freed from suspended mineral matter and then heated and subjected to a prolonged treatment with air or other oxidising gas supplied in the form of a number of fine jets: the temperature should not be raised above 400°—500° C., and the heating is stopped before carbonisation begins. The mass thus produced is extracted with benzene or petroleum and the residue is carbonised by heating. The extract is distilled and the residue is submitted, either alone or mixed with other hydrocarbons to be carbonised, to the same treatment by oxygen and heat.—T. F. B.

5(4)-Methyl-4(5)-arylaminomethyliminazoles; Preparation of ——. O. Gerngross. Ger. Pat. 276,541, July 23, 1913.

The Schiff's bases obtained by condensing 5(4)-methyliminazyl-4(5)-glyoxylic acid with a primary aromatic amine of the benzene series, are treated with an alkaline reducing agent; the products have the constitution:—

$$\begin{array}{l} CH_3.C.NH\diagdown \\ \quad\ \ \ddot{C}—N\!\!/\!\!/ \quad CH \\ \quad\ \ \dot{C}H_2.NH.Aryl. \end{array}$$

—T. F. B.

Process for increasing the fungicidal and insecticidal properties of the nitrogenous bases from tar or tar oils. Ger. Pat. 276,685. *See* XIXb.

IV.—COLOURING MATTERS AND DYES.

6.6′-Dimethylindigotin; p-Toluoylacetic acid, o-nitro-p toluoylacetic acid and ——. J. C. Duff. Chem. Soc Trans., 1914, **105**, 2182—2186.

The sodium salt of ethyl-o-nitro-*p*-toluoylacetoacetate was prepared from the corresponding aceto-*p*-toluidide and by hydrolysis with ammonia and ammonium chloride gave ethyl-*o*-nitro-*p*-toluoylacetate. This mixed with twice its weight of concentrated sulphuric acid, heated to 80° C. and poured on to ice, yielded *o*-nitro-*p*-toluoylacetic acid, which crystallises from benzene as colourless needles melting with decomposition at 110° C. Its solution in alcohol gave a deep red colour with ferric chloride solution and when boiled with water evolved carbon dioxide forming a yellow oil, proved to be *o*-nitro-*p*-tolyl-methy ketone similar to *o*-nitro-acetophenone. On dissolving *o*-nitro-*p*-toluoylacetic acid in ten times its weight o 10% sodium hydroxide solution, a 50% yield of an indigo blue precipitate of 6.6′-dimethylindigotin was obtained —G. H. F.

o-Cyanophenol; Nitro- and amino-derivatives of —— Cousin and Volmar. J. Pharm. Chim., 1914, 10 231—237.

A mixture of equal weights of glacial acetic and nitri acids was added to a cooled solution of *o*-cyanopheno (salicylic acid nitrile) in glacial acetic acid. On dilutin with water at first nitro-3-*o*-cyanophenol and later nitro 5-*o*-cyanophenol separated. The former crystallised from alcohol in fine golden-yellow crystals, m. pt. 132°—133° C Amino-3-*o*-cyanophenol melted at 145° C., rapidly turne grey on exposure to light, and gave a hydrochloride m. pt. 130° C. Amino-5-*o*-cyanophenol, m. pt. 155—160° C. (Maquenne block), gave a hydrochloride, m. p 180° C. (Maquenne block) and also darkened on exposur to light. The diazo compound combined with amines an phenols to give orange to red dyestuffs.—F. Shdn.

Researches on chlorophyll. XXIV. Colouring matters of brown algæ. R. Willstätter and H. J. Page. Annalen, 1914, **404**, 237—271.

Chlorophyll is present in brown algæ accompanied by three yellow colouring matters, fucoxanthin, carotin and xanthophyll, the proportion of yellow colouring matters to chlorophyll being much greater than in land plants. To extract the pigments the fresh algæ are extracted with 40% acetone which removes much slimy matter, then ground and extracted with 85% acetone. The first extracts are yellowish brown and contain chiefly fucoxanthin. The different colouring matters can be separated by taking advantage of their varying solubilities in dilute methyl alcohol and ether-petroleum spirit, but the process is long and tedious. The chlorophyll of brown algæ consists almost entirely of chlorophyll *a*, not more than 5% of chlorophyll *b* being present. Fresh *Fucus virsoides* contains about 0·05% chlorophyll *a*, 0·017% fucoxanthin, 0·009% carotin and 0·009% xanthophyll. Fucoxanthin, $C_{40}H_{54}O_6$, m. pt. 159·5°—160·5° C., crystallises from methyl alcohol in monoclinic prisms containing 3 mols. CH_3OH, or in hexagonal plates with 2 mols. H_2O and from ether-petroleum spirit in needles. With ethereal hydrogen chloride it gives a hydrochloride, $C_{40}H_{54}O_6.4HCl$, m. pt. 215° C., and with iodine in carbon bisulphide a tetraiodide, $C_{40}H_{54}O_6.I_4$, m. pt. 134°—135° C.—T. C.

Coal-tar dyes. Ch. of Comm. J., Oct., 1914. [T.R.]

The value of the imports of coal-tar dyes to the United Kingdom from Germany in 1913 was: alizarin and anthracene dyes, £271,119; aniline and naphthalene dyes, £1,382,478; synthetic indigo, £76,681; other kinds, £543; total, £1,730,821. Not only has the demand in this country to be met but also the important requirements of India, Japan, China, Turkey, Egypt, etc. India imported from Germany in 1911–12 aniline dyes to the value of £339,248, alizarin dyes £140,279, and synthetic indigo £37,412. Japan in 1913 imported from Germany aniline dyes to the value of £372,022, alizarin dyes £26,494, and artificial indigo £301,052. China imported from Germany in 1911 artificial indigo to the value of about £575,000.

Coal tar colours; Development of domestic ——. Paper read before the New York Section of the American Chemical Society, October 9, 1914. By I. F. Stone. Oil, Paint, and Drug Rep., Oct. 12, 1914. [T.R.]

If the United States were to be independent of Germany, the intermediate products must be made on a large scale. This would require a protective duty sufficient to allow the business to be developed. The present duty of 10% was insufficient, by reason of the convention which controlled the manufacture in Germany and immediately reduced the price by an equivalent amount. This had happened in the case of aniline oil, the manufacture of which was begun about three years ago by the Schoellkopf Anilin Works at Buffalo, and which furnished now about one-quarter of the consumption of the United States, taking oil and salts as one product. The unfair competition of Germany could be readily checked if the Government would incorporate in their tariff what was known as the "dumping" clause which forbids the importation into and the selling in the United States of any products at a less price than they are sold in the country where they were produced. The Schoellkopf factory produced aniline oil thirty years ago, but had to abandon it owing to being unable to obtain benzol. That was no longer a difficulty; moreover, by-product coke ovens could readily be established to increase the supply.

There was also the manufacture of explosives to increase the consumption of intermediate products. No Government could afford to be dependent on a foreign supply of such bodies as trinitrotoluol and carbolic acid. In self-defence it must create some sort of tariff or subsidy to protect the industry. Dr. Hesse had stated that out of 900 dyes, 76 were made in the United States. The real number was about 100, and when it was remembered that many of the 900 were defective or obsolete, the proportion was larger than appeared on the surface. They could satisfy 90% of U.S. colour demands, referring to types not quantities, the remaining 10% being mainly alizarin and indigo.

The amount of dyestuffs imported into the U.S.A. in 1913 was:—

Aniline dyes	$7,000,000
Indigo	1,000,000
Alizarins	1,500,000

These were cost prices, and when the United States duty of 30% and the expenses were added, it meant that Americans were paying about $12,000,000 for their supplies, not including the home manufacture which might be $2,000,000 more.

The author then combated some statements of the "Scientific American" in regard to a protective tariff—and considered that a higher tariff would stimulate production and competition and that competition would always control the price. Indigo and alizarin were not made in America and there was no duty on them. Yet customers had to pay more for them, because their prices were controlled by a combination.

Direct Cotton Black was made in America and there was an import duty of 30% on it. In consequence the Europeans had been compelled to reduce their selling prices in America to less than they were charging their customers in Europe.

The author also demanded a revision of the United States patent laws on the lines of the recent British amendments. In 1909 this was proposed, but Germany negotiated a treaty by which the German working clause was made inoperative on American inventions. Whether this was beneficial was a question, but it certainly did not benefit the United States coal tar industry.

From 1880 to 1883, when there was an import duty of 35% ad val. and 50c. per lb., specific, there were ten dye factories in U.S.A. In 1883 the specific duty of 50c. was abolished, and within one year five of these factories succumbed, and now only four were left, and these had had a great struggle to maintain themselves.

The change in the patent laws was of less importance in the case of colours than in other lines, as there were quite enough dyes on which the patents had expired to constitute a large industry.

America could manufacture dyes if it were made commercially possible, but whenever conditions became normal, without protection, they would have to give up the manufacture of intermediate products because they could get them cheaper in Europe than they could make them.

Patents.

Azo dyestuffs; Manufacture of substantive ——, which are rendered faster by after-treatment with formaldehyde. Kalle und Co. A.-G. Ger. Pat. 276,546, Nov. 20, 1912.

A mononitrobenzoyldiamine is diazotised and combined with 2.5.7-aminonaphtholsulphonic acid or an N-derivative thereof, the nitro-group is reduced, and the dyestuffs thus produced are diazotised and combined with one or more mols. of resorcinol or *m*-aminophenol or their homologues or derivatives.—T. F. B.

Producing colouring matter for paper-making and similar manufactures. U.S. Pat. 1,110,775. *See* V.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Paper; Tests for determining quality of ——. K. B. Lamb. Chem. News, 1914, **110**, 180—181.

The various tests applicable to papers are classified.—J.F.B.

The dyeing of army cloths. Chem. Trade J., Oct. 17, 1914. [T.R.]

The Association of Chambers of Commerce have received a communication from the War Office as to the standard exacted by the Department in respect of the dyeing of Army cloth. This states that "owing to the probable exhaustion of the stock of dyeing stuffs which have hitherto been obtained from abroad, it has for some time past been decided to allow other coal-tar and vegetable dyestuffs in the production of drab mixture materials, provided that the dye is the fastest that can be obtained, and approximates closely in colour to the standard pattern."

Patents.

Fibres, gums and juices from fibrous plants; Apparatus for obtaining ——. F. V. Raymond, Invercargill, W. O. Beere, Wellington, and J. E. Rough, Foxton, New Zealand. U.S. Pat. 1,107,840, Aug. 18, 1914; date of appl., Sept. 11, 1912.

The apparatus consists of a plain drum with a series of rollers pressing against its periphery. The fibre passes between the drum and the rollers, the pressure being increased at each successive roller. Conduits are provided for conducting away expressed juices, also water sprays and scrapers for cleaning the rollers.—J. B.

Porous fabrics; Treating textile and other ——. F. J. Staunton, Milwaukee, Wis. U.S. Pat. 1,108,408, Aug. 25, 1914; date of appl., July 30, 1913.

A liquid composed of a base pigment, a binding medium for the pigment, and a thinning material in amount not less than 32% of the whole is applied to the material, whereby its porous nature is preserved.—J. B.

Drying apparatus [for textiles]. E. Feuillette, Assignor to Soc. Etablissements E. Feuillette, Boulogne-sur-Seine, France. U.S. Pat. 1,108,565, Aug. 25, 1914; date of appl., Jan. 6, 1914.

An installation for drying flax, hemp, or other textile materials by circulating hot gases over them, comprises a fixed drum for the introduction of hot gases, and a series of horizontal drying chambers carried on rails on traversing trucks so that they can be brought into position and connected with the fixed drum. The chambers have inclined supports for the material arranged so as to form parallel undulating passages for the gases which are thus caused to mix and render the drying uniform. The roof of each chamber is formed by a pair of plates hinged on a transverse rod.—A. T. L.

Fibrous substances of all kinds; Process for impregnating ——. Anhydat Leder-Werke A.-G. Ger. Pat. 276,619, June 24, 1913. Addition to Ger. Pat. 273,652 (see this J., 1914, 759).

The material is immersed in a solution of asphaltum or similar material, and then in a molten substance soluble in the solvent first used; a substance insoluble in this solvent may be applied before the final treatment, if necessary. *Example:* The material is treated with a solution of petroleum tar in benzene, and then immersed for 24 hours in a mixture of 90—95 parts of petroleum tar and 10—5 parts of boiled linseed oil, heated to 85°—110° C. —T. F. B.

Bamboo and the like; Process for the production of paper pulp or cellulose from ——. J. L. Jardine, Penicuik, and T. A. Nelson, Edinburgh. Eng. Pat. 18,371, Aug. 13, 1913.

Bamboo, previously crushed, is digested with a solution of magnesium or sodium bisulphite which may initially contain an excess of SO_2. During the heating up of the charge the SO_2 not absorbed by the material is allowed to escape freely and during the whole course of the digestion the accumulation of liberated SO_2 in the digester is prevented by a suitable continuous or intermittent discharge of the gases. The pressure in the digester must correspond only with the pressure of steam at the temperature employed. A suitable liquor, made from a magnesium base, may contain initially 3·25% of total SO_2, of which 1·45% is combined. The full pressure of 75 lb. per sq. in. is attained in 4—5 hours and digestion is continued for 10—12 hours with live steam until the total SO_2 is reduced to about 1%.—J. F. B.

Pulping engines and the like. R. J. Marx, London. Eng. Pat. 5018, Feb. 26, 1914.

In a pulping or kneading engine into which water and steam are passed simultaneously with the waste paper or other material to be pulped, both the revolving members on the shaft and the stationary members, which may be cast on the shell, are provided with detachable and exchangeable end-pieces made of wear-resisting material, such as tempered steel, so that the predetermined clearances between the members may be maintained without change.—J. F. B.

Sulphite fibre: Reclaiming waste products [SO_2] in the manufacture of ——. H. K. Moore and R. B. Wolf, Berlin, N.H. U.S. Pat. 1,110,454, Sept. 15, 1914; date of appl., Dec. 30, 1913.

In connection with a sulphite pulp digester a blow-pit is provided having a vomit stack with a removable cap and connected with a surface condenser. The blow-pit is filled with steam to expel the air and then connected with an air-pump; the contents of the digester are discharged into the pit, the vapours rising from which are condensed and the sulphur dioxide separated and recovered.—J. F. B.

Colouring matter for paper-making and similar manufactures; Process of producing ——. J. Hahn, Buffalo, N.Y. U.S. Pat. 1,110,775, Sept. 15, 1914; date of appl., Oct. 8, 1913.

A pigment is thoroughly mixed with rosin size and water and the mixture precipitated by a suitable salt; the supernatant liquid is separated and the precipitate washed with water, drained and dried.—J. F. B.

Wool-scouring and analogous liquors; Recovery of ingredients from ——. W. G. Abbott, jun., Wilton, N.H. U.S. Pat. 1,110,277, Sept. 8, 1914; date of appl., Jan. 2, 1913.

The liquor is heated to about 165° C. under pressure until the fatty matters are separated, the light grease collecting at the top as the liquor cools and the heavy grease settling to the bottom.—J. F. B.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Patents.

Woollen goods; Treatment of —— *[to render them less liable to absorb moisture].* A. E. Garrett, St. Albans, Herts. Eng. Pats. 29,512, Dec. 22, 1913, and 2394, Jan. 29, 1914.

Woollen goods that have been rendered unshrinkable by chlorination, etc., absorb moisture much more readily than the untreated stuff. This defect is remedied by treatment in a weak soap bath containing from 4 to 15 c.c. of ammonia (sp. gr. 0·880) per litre at not above 50° C., 1 litre of liquor being allowed for each 60 grms. of fabric. The goods are afterwards rinsed thoroughly, bleached with peroxide if necessary, and finished.—J. B.

Dyeing and sizing warps and apparatus therefor. J. Pyrah, Bradford. Eng. Pat. 24,851, Oct. 31, 1913.

The warp is dyed, squeezed, and after a short passage through the air and whilst still warm, is passed directly into the sizing bath and thence to the drying machine. Continuous dyeing and sizing machines are used with the necessary distance between them for the air passage, and the warp is taken from back beams and finally wound on to loom beams.—J. B.

Dyeing apparatus. A. J. and J. A. Rau, Clifton, N.J. U.S. Pat. 1,108,233, Aug. 25, 1914; date of appl. March 4, 1914.

The web of material passes under a perforated drum as it travels through the dye-vat. Means are provided for removing liquor from the inside of the drum to the body of the vat so that there is an excess hydrostatic pressure on the outer side of the drum.—J. B.

Fabrics; Apparatus for treating ——. C. Buhl, Assignor to D. McCausland, Paterson, N.J. U.S. Pat. 1,109,819, Sept. 8, 1914; date of appl., Feb. 25, 1914.

A hollow perforated drum revolves on a horizontal axis in a tank containing the liquid with which the fabric is to be treated. The fabric is guided through the liquid in contact with the walls of the drum. Means are provided for producing a difference in pressure between the interior and exterior of the drum and for closing communication through the perforated portion which is not covered by the fabric under treatment.—J. F. B.

Dyeing textile materials; Apparatus for ——. W. R. Smith, Assignor to Buffalo Leather Co., Buffalo, N.Y. U.S. Pat. 1,111,104, Sept. 22, 1914. Date of appl., March 1, 1913.

See Eng. Pat. 294 of 1913; this J., 1913, 866.—T. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Potash from felspar and other sources; The preparation of ——. Chem. News, 1914, **110**, 175.

In view of the stoppage of supplies of potassium salts from Germany, attention is directed to a process developed by Ward and Wynants (Eng. Pat. 3185, Dec. 30, 1857) for the extraction of potassium salts from felspar, which at the time was found to give thoroughly satisfactory results. Felspar ground to the fineness of Portland cement was mixed with powdered fluorspar or other fluoride, the fluorine being calculated equivalent to the alkali in the rock. A mixture of chalk and lime was then mixed with the materials so that the proportion of Ca was double that of the SiO_2 and one and a half times that of the Al. On the large scale it was found preferable to employ about 10% excess of lime. The mixture was made into cakes and heated to a yellowish-red for a few hours. The porous frit obtained was lixiviated with boiling water which extracted 90% of the potash originally present in the rock in the form of hydroxide and carbonate. The residue might be worked up into hydraulic cement by removing the fluorine. Another possible source of potash is the spent wash from the fermentation of molasses from the beet sugar industry. The wash, neutralised by chalk, is decanted, evaporated and calcined. The crude ash, if calcination has been carefully performed, contains about 50% of potassium salts. Lastly the revival of the kelp industry appears by no means impracticable as a source of potash, with the additional advantage of yielding iodine.—J. F. B.

(a) *Magnesium carbonate, carbonic acid, and water; and* (b) *calcium carbonate, magnesium carbonate, carbonic acid, and water; The systems* ——. J. W. Leather, and J. N. Sen. Mem. Dept. Agric., India, Chem. Ser., 1914, **3**, 205—234. (See also Mem. Dept. Agric., India, Chem. Ser., 1909, **1**, No. 7).

From a study of the system $H_2O,MgCO_3,CO_2$, at 20°, 25°, 30°, 34°, and 39° C., it is found that the concentration of bicarbonate for any specified partial pressure of CO_2 is from 5 to 15 times greater than in a similar system containing Ca instead of Mg; that the solution contains only a small excess of H_2CO_3 beyond the unimolecular ratio $MgCO_3 : H_2CO_3$, and that the solution of $MgHCO_3$ is more stable than that of $CaHCO_3$. From a study of the system $H_2O,CaCO_3,MgCO_3,CO_2$ between 23° and 30° C., it is found that $CaCO_3$ is not dissolved by CO_2 and water in presence of $MgCO_3$, that while dolomite is thus dissolved it is protected partially by $CaCO_3$ and completely by $MgCO_3$, that a small quantity of $MgCO_3$ is precipitated by $CaCO_3$ from the dolomite solution, and that the treatment of soil with $MgCO_3$ may cause a precipitation of $CaCO_3$, and render it infertile.—O. E. M.

Potassium nitrate, sodium chloride, water; The system ——. J. W. Leather and J. N. Mukerji. Mem. Dept. Agric. India, Chem. Ser., 1914, **3**, 177—201.

The results of the study of several systems between the temperatures 20°—91° C. are reproduced in copious tables. In general, in the case of the systems $NaCl,KCl,H_2O$; KCl,KNO_3,H_2O; and $NaNO_3,NaCl,H_2O$, either salt decreases the solubility of the other: in the system $KNO_3,NaNO_3,H_2O$, either salt increases the solubility of the other: in the system $KNO_3,NaCl,H_2O$, up to a limit of concentration, either salt increases the solubility of the other, except that near 40° C. the solubility of KNO_3 is unaffected by the addition of NaCl. The conditions under which the various solid phases can occur are described in detail.—O. E. M.

Iodine and bromine in haloid salts; Determination of —— *by means of telluric acid.* H. I. Cole. Amer. J. Sci., 1914, **38**, 265—272.

The method previously described for bromine (this J., 1914, 352) has been modified to include the determination of iodine by dividing the distillation into two stages, in the first of which very dilute sulphuric acid is used. The graduated, tubular distillation flask is provided with an adjustable electric heating collar, and a steam flask is inserted between the distillation flask and the carbon dioxide generator. The salt is introduced, together with 50 c.c. of water, into the tubular flask, and this is connected with a receiver (immersed in ice-water) charged with 200 c.c. of a 1·5% solution of potassium iodide: 1 grm. of telluric acid, dissolved in 15 c.c. of sulphuric acid, sp. gr. 1·015, is added, the volume made up to 100 c.c. with water, and carbon dioxide and steam are passed very slowly through the mixture, which is not allowed to concentrate below 100 c.c., until all traces of free iodine have been expelled; the mixture is then evaporated, with only sufficient steam to prevent the return of any colour, to 64—67 c.c., and, after necessary cooling, the liberated iodine in the receiver and trap is titrated with thiosulphate. The receiver is again charged with 200 c.c. of potassium iodide solution, 10 c.c. of sulphuric acid (1 : 1) are introduced into the flask, carbon dioxide is passed very slowly through the apparatus, and as soon as the boiling mixture becomes discoloured, steam is passed in at a rate just sufficient to compensate for the vapour carried over, until all the colour is removed. The concentration is slowly continued, with the help of steam, to a volume of 30 c.c., the remaining solution rapidly boiled down to 24 c.c., and the free iodine titrated as before, its amount being taken as a measure of the bromine expelled. The method allows the determination of iodine or bromine up to 0·3 grm. when associated in haloid salts with amounts of chlorine up to 0·25 grm., the entire operation occupying not more than two and a half hours.—F. Sodn.

Iron-cyanogen compounds; Blue ——. H. E. Williams. J. Chem., Met. and Min. Soc., S. Africa, 1914, **15**, 1—5.

Blue compounds prepared by the interaction of alkali ferrocyanide and ferric salts in most cases contained alkali metal in a definite ratio to the ferrocyanogen. Those prepared from ammonium and potassium ferrocyanides were very similar in composition and appearance, but sodium ferrocyanide gave products containing a lower proportion of alkali metal, with sometimes a large proportion of combined water, and the air-dried compounds were relatively low in density, light in colour, and almost devoid of bronze lustre. $Fe_2'''(NH_4)_6[Fe(CN)_6]27H_2O$ was obtained as a fine green powder by adding an ammoniacal solution of ferric tartrate, containing ammonium tartrate, to a large excess of ammonium ferrocyanide solution, and gradually introducing hydrochloric acid so as to liberate the organic acid only; further addition of mineral acid gave a blue compound

$Fe_8'''(NH_4)_{12}[Fe(CN)_6]_9,52H_2O$. With potassium salts, a green compound was similarly formed, but this changed on washing to the dull blue, $Fe_{10}'''K_{18}[Fe(CN)_6]_{12},45H_2O$ and, on further addition of acid, to $Fe_8'''K_{12}[Fe(CN)_6]_9$ corresponding to the ammonium compound above. A dilute solution of ammonium ferrocyanide reacted with an excess of dilute ferric chloride to give $Fe_7'''(NH_4)_3[Fe(CN)_5]_6,50H_2O$, and the same compound was obtained by adding ammonium ferrocyanide to a boiling excess of ferric chloride, but when, in the latter case, the ferric solution contained excess of potassium chloride, or when ferric chloride solution was added, in slight excess, to a solution of potassium ferrocyanide containing ammonium chloride, $Fe_7'''(NH_4)_2K[Fe(CN)_6]_6,50H_2O$ was precipitated. The sodium salt $Fe_7'''Na_3[Fe(CN)_6]_6,50H_2O$ was prepared by oxidising white ferrous sodium ferrocyanide with an excess of ferric chloride or (with $24H_2O$) by treating a boiling solution of ferrous sodium ferrocyanide with excess of ferric chloride. $Fe_{11}'''K_3[Fe(CN)_6]_9,100H_2O$ was precipitated by adding a ferric salt in slight excess, to potassium ferrocyanide solution, or a large excess of the iron salt to ferrocyanide solution containing an equivalent quantity of potassium chloride, and the same salt, with $81H_2O$, was prepared by agitating freshly prepared ferrous potassium ferrocyanide with excess of ferric chloride solution; the sodium salt, $Fe_{11}Na_3[Fe(CN)_6]_9.90H_2O$, was obtained by oxidising ferrous sodium ferrocyanide with dilute chromic acid in the cold. $Fe_9'''K[Fe(CN)_6]_7.78H_2O$ was prepared by adding potassium ferrocyanide to a boiling excess of ferric chloride, and with sodium ferrocyanide a precipitate of composition $Fe_{13}'''Na[Fe(CN)_6]_{10},100H_2O$ was obtained, the same compound being formed by precipitating sodium ferrocyanide solution with an excess of ferric chloride; a dilute solution of sodium ferrocyanide containing twice the equivalent quantity of ammonium chloride, when precipitated in the cold with a large excess of ferric chloride, gave $Fe_{22}'''(NH_4)_9Na[Fe(CN)_6]_{19},140H_2O$. Freshly precipitated and washed copper ferrocyanide on boiling for some hours with excess of ferric chloride, yielded $Fe_2'''Cu''[Fe(CN_6)]_2,28H_2O$, as a rather light blue powder. All the above are regarded as molecular compounds of ferric ferrocyanide and the double salt $Fe_2'''M_6'[Fe(CN)_6]_3$; and the blue and green ferrosoferric ferrocyanides previously described (this J., 1913, 286), as molecular compounds of the same double salt with $Fe''M_2'Fe(CN)_6$ or with ferrous ferrocyanide. $Fe_2'''Fe_2''K_6[Fe(CN)_6]_4$ was prepared as a dull blue precipitate by adding ferric chloride solution to a large excess of potassium ferrocyanide and boiling the mixture for some time.—F. Sodn.

Lead; The arsenates of ——. H. V. Tartar and R. H. Robinson. J. Amer. Chem. Soc., 1914, **36**, 1843—1853.

Pure $PbHAsO_4$ was prepared, as a white amorphous powder, by treating lead nitrate solution with disodium arsenate, washing the precipitate, dissolving in the minimum quantity of nitric acid, slowly adding dilute ammonia, with constant stirring, until about three-fourths of the acid were neutralised, allowing to stand overnight, filtering, washing the precipitate with water slightly acidified with nitric acid, and then with boiled water until free from nitrates, and drying at 110° C. When fused at a dull red heat, it gave the pyroarsenate, and, by heating with ammonia, a basic salt, $21Pb_3(AsO_4)_2,2Pb(OH)_2,10H_2O$. The precipitates formed by treating lead acetate or nitrate with disodium arsenate were, in each case, mixtures of the acid and basic salt, both of which are insoluble in water. The sp. gr. of $PbHAsO_4$ at 20°/4° C. was 5·786, and that of the basic salt, 7·105. The acid arsenate is determined in commercial arsenate of lead by digesting 3—10 grms. (dried at 100° C.) for a few hours, at the ordinary temperature, with 200 c.c. of a 5% solution of ammonia (free from carbonate), filtering by means of a Buchner funnel, prepared with a pad of two sheets of filter paper, with a layer of asbestos between (the upper paper being a hardened filter), washing with boiled water until the washings give no turbidity with lead nitrate, and determining arsenic in an aliquot part of the clear filtrate, after boiling off ammonia, by the modified method of Gooch and Browning (Bull. 107 (Revised), Bur. Chem., U.S. Dept. Agric.). The amount of arsenic in the total filtrate, calculated as As_2O_3 and multiplied by the factor 7·6034, gives the weight of $PbHAsO_4$ present in the original mixture.—F. Sodn.

Thorium ammonium oxalate. C. James, C. F. Whittemore, and H. C. Holden. J. Amer. Chem. Soc., 1914, **36**, 1853—1856.

A study of the solubility curves of thorium oxalate and ammonium oxalate, in the presence of each other, in water at 25° C., indicated the existence of only two double salts, probably $2Th(C_2O_4)_2,(NH_4)_2C_2O_4,2H_2O$ and $2Th(C_2O_4)_2,(NH_4)_2C_2O_4,7H_2O$ (compare Brauner, this J., 1898, 372).—F. Sodn.

Boron; Amorphous —— and magnesium boride. R. C. Ray. Chem. Soc. Trans., 1914, **105**, 2162—2168.

The so-called amorphous boron prepared from boron trioxide and magnesium always contains a considerable quantity of oxygen and magnesia. It is probably a solid solution of a lower oxide of boron, possibly combined with the magnesia as borite, in elementary boron in the amorphous state. The magnesia may be removed by fusion with boron trioxide, but not by heating with acids. The only form of boron in an approximately pure state is the crystalline variety, which is practically insoluble in nitric acid. It will not combine with magnesium directly, but amorphous boron treated with magnesium yields Mg_3B_2, which appears to be the only boride of magnesium formed at a red heat and under normal pressure. On heating this boride strongly magnesium is driven off, and the greater part of the boron separates in the crystalline state.—G. F. M.

Erratum.

Page 960; col. 2; line 5 from bottom, *for* "W. H. C.," *read* "W. C. H."

Patents.

Sulphuric acid manufacture. U. Wedge, Ardmore, Pa. U.S. Pat. 1,106,999, Aug. 11, 1914; date of appl., Oct. 2, 1912. Renewed June 25, 1914.

The chambers are operated so as to maintain in the exit gases a predetermined percentage of sulphur dioxide insuring the best recovery of nitre in the Gay Lussac towers.—F. Sodn.

Boric acid; Process for the production of ——. A. Burger, New Brighton, N.Y. U.S. Pat. 1,108,129, Aug. 25, 1914; date of appl., Jan. 22, 1914.

A borate, *e.g.*, natural calcium borate, is calcined and treated with carbon dioxide in the presence of water, the resulting acid borate decomposed, preferably with a mineral acid under pressure, and the boric acid separated.—F. Sodn.

Ferrous liquors; Process of utilising waste ——. W. F Oesterle, jun., C. A. Beale, and J. McFetridge, Vandergrift, Pa., Assignors to American Sheet and Tin Plate Co., Pittsburgh, Pa. U.S. Pat. 1,108,387, Aug. 25, 1914; date of appl., Oct. 10, 1913.

The liquor is neutralised (*e.g.*, with ferric oxide) and then oxidised and used as a depolariser in the electrolytic cleaning of metals with acid solutions. Oxidation may be effected by "furnacing," the soluble salts being extracted from the product by water.—F. Sodn.

Saline solutions; Method and means for electrolysing ——. E. A. Allen, Rumford Falls, Me. U.S. Pat. 1,109,311, Sept. 1, 1914; date of appl., Jan. 6, 1912.

The electrolyte is confined between horizontal diaphragms, of which the lower rests upon an unimmersed carbon anode, whilst the upper is covered by a mercury cathode in contact with water. An electric current is passed from the anode, through the electrolyte and superposed mercury and water, to terminal electrodes above, so as to liberate metal in contact with the under surface of the mercury and cause it to form a hydroxide with the water at the upper surface, setting free chlorine at a point out of contact with the body of the electrolyte. Means are provided for circulating electrolyte between the diaphragms and for supplying water to the cathode space.—F. Sodn.

Aluminium fluoride; Process of obtaining ——. C. A. Doremus, New York. U.S. Pat. 1,110,675, Sept. 15, 1914; date of appl., April 2, 1914.

Aluminium fluoride is obtained in the anhydrous form, or with variable amounts of water of crystallisation, by heating, and preferably stirring, its solution in a closed vessel.—F. Sodn.

Potassium salts; Preparation of magnesium oxide and hydrochloric acid from the waste lyes from the manufacture of ——. E. Dietz. Ger. Pat. 275,617, July 5, 1913.

The waste lyes are evaporated to remove excess of potassium and sodium chlorides, and electrolysed, with or without the use of a diaphragm. Magnesium hydroxide is first formed at the cathode, but as the electrolysis proceeds it is converted into the oxychloride, which is removed and heated to produce hydrochloric acid and magnesium oxide.—T. F. B.

Nitrogen with hydrogen or with oxygen; Catalytic combination of ——. F. Hlavati. Ger. Pat. 275,663, March 15, 1910.

The catalyst consists of a mixture of a metal of the platinum group and a metal which is capable of combining with nitrogen, precipitated together on a porous carrier. For example, pumice is impregnated with a solution containing a titanium salt and a platinum salt, and treated with a reducing agent.—T. F. B.

Alkaline silicate; Process of producing a ferrated and borated ——. T. Rouse, Stamford Hill, Assignor to Bessler Waechter und Co., Ltd., London. U.S. Pat. 1,109,704, Sept. 8, 1914. Date of appl., Feb. 9, 1911.

See Eng. Pat. 21,563 of 1910; this J., 1911, 956.—T. F. B.

Hydrogen peroxide; Stable —— and method of making the same. A. Schadhauf, Frankfort, Germany, Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,109,791, Sept. 8, 1914. Date of appl., June 20, 1912.

See Ger. Pat. 263,650 of 1912; this J., 1913, 1010.—T. F. B.

Nitrates and nitrites; Process of obtaining —— from nitrate-nitrite mixtures. E. Collett. Assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,110,481, Sept. 15, 1914. Date of appl., Feb. 9, 1911.

See Fr. Pat. 425,997 of 1911; this J., 1911, 1014.—T. F. B.

Process of making carbon monoxide, hydrogen, and nitrogen. U.S. Pats. 1,107,581 and 1,107,582. *See* IIa.

Manufacture of carbon. Eng. Pat. 6354. *See* III.

[*Medicinal*] *Table salt.* Eng. Pat. 22,322. *See* XX.

VIII.—GLASS; CERAMICS.

Fireclay in coal-mines. J. W. Mellor. Times Eng. Suppl., Sept. 25, 1914, 114.

A small number of samples of clay from North Staffordshire coal-mines have been tested with satisfactory results and the author suggests that a valuable source of fireclay is being overlooked. One sample collapsed only at the same temperature as Seger cone No. 33, a good British fireclay collapsing at about cone No. 30 or 31, *i.e.*, at a lower temperature.—A. T. L.

Patents.

Porcelain kiln. H. C. Kapelle, Schenectady, N.Y. U.S. Pat. 1,108,585, Aug. 25, 1914; date of appl., Jan. 2, 1914.

The kiln comprises an outer wall and a central masonry mass, about which alternating direct and indirect firing holes (with intervening equalising flues) are radially disposed. The direct firing holes extend to the centre of the kiln over the masonry mass, and the indirect firing holes terminate short of the centre. A baking chamber, situated above the firing holes, communicates with these by openings in the chamber bottom, and the inner ends of those flues which extend to the centre of the kiln join beneath the central opening.—F. Sodn.

Ceramic material. A. Malinovsky, Assignor to H. H. Randolph, Chicago. U.S. Pat. 1,110,449, Sept. 15, 1914. Date of appl., March 13, 1912.

See Fr. Pat. 456,837 of 1913; this J., 1913, 1069.—T. F. B.

IX.—BUILDING MATERIALS.

Paint protection of Portland-cement surfaces. Gardner. *See* XIII.

Patents.

Cement kilns and the like [; Rotary ——]. W. J. Mellersh-Jackson, London. From T. J. Fleming, Los Angeles, Cal., U.S.A. Eng. Pat. 19,877, Sept. 2, 1913.

A draught through the kiln is produced by means of a fan which also forces the waste gases through a primary dust house (preferably with metal walls), having baffles and grills for separating the heavier dust particles, into a secondary dust house fitted with a series of baffles ensuring a tortuous passage and a second series arranged to intercept water sprayed from above. The fan is driven by a motor provided with a controlling rheostat for regulating the draught conditions. The discharge of dust has been reduced by one such installation from 22 tons to 200 lb. *per diem.*—F. Sodn.

Cement; Water-repellent —— and process of making same. C. Ellis, Montclair, N.J. U.S. Pat. 1,109,120, Sept. 1, 1914; date of appl., Feb. 20, 1912.

Cement is mixed with an emulsion containing mineral oil, soap solution, and an insoluble soap.—A. T. L.

Concrete composition; Waterproof ——. H. M. Olson, Beaumont, Cal. U.S. Pat. 1,109,540, Sept. 1, 1914; date of appl., Aug. 26, 1912.

A mixture of lime, 10 lb., crude oil, 1 gall., and water. —A. T. L.

Mortar made of lime and sand; Method of dressing ——. C. Siedentopf, Magdeburg, Germany. U.S. Pat. 1,108,406, Aug. 25, 1914; date of appl., Nov. 24, 1913.

Mortar from a previous "dressing," whilst still hot, is incorporated with a fresh mixture of lime and sand, for the purpose of substituting the heat of the already dressed mortar for the heat from slaking.—F. Sodn.

Mortar; Process for preparing dry —— from lime and sand. Mörtelwerk Jolit G. m. b. H. Ger. Pat. 275,607, Oct. 23, 1912.

Quicklime is mixed with sand and calcium carbonate and heated in presence of water at 80°—100° C. Magnesium, calcium, aluminium, ammonium, or ferric chloride may also be added to the mixture.—T. F. B.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron-ore deposits of Eastern and Western France. P. Nicou. Iron and Steel Inst., 1914. [Advance proof.]

A STATISTICAL and geological description, with two maps of the great French ore-fields is given. The western field, which is the more favourably situated geographically for the supply of ore to Great Britain, includes Normandy, producing hæmatite with a maximum of 55% Fe, and carbonate ores containing, after calcination, up to 50%, and Anjou and Brittany, producing oolitic iron ore, hæmatite, and magnetite, with about 55% Fe and 13—20% SiO_2. The eastern field, French Lorraine, yields a hydrated oolitic hæmatite containing from 33 to 40% Fe, and phosphorus in such ratio that iron containing P 1·7 to 1·9% can be produced with regularity.—O. E. M.

Blast-furnace stoves; A new process for heating ——. A. Spannagel. Iron and Steel Inst., 1914. [Advance proof.]

THE process consists essentially in forcing the heating gases through the stoves at a high velocity, experiments having shown that whilst at first the temperature of the exit gases rises when the velocity is increased, the reverse is the case after a critical point is passed. In the first tests rough-cleaned gas (containing about 0·5 grm. of dust per cubic metre), at a pressure of 4 ins. water-gauge was forced through the stove by the aid of air under a pressure of 12 ins. For a blast temperature of 800° C. the heating period was reduced from 4½—5 to about 1½ hours and the maximum temperature of waste gases from 700° to 350° C., as compared with former conditions. By using highly-cleaned gas it was possible to reduce the cross-section of the heating passages. In an installation at Neunkirchen the stoves are fitted with octagonal bricks having passages of 75 mm. diam. and so disposed as to leave an additional passage, 50 mm. sq., in the centre of each group of 4 bricks. Lateral openings are also provided at one end of the bricks to allow the gases to pass even if the vertical path is blocked. Using air at a pressure of 16 ins. water-gauge to force the gases through the stoves, the waste gases were 90°—116° C. at the end of the heating period of 1½ hours, as compared with 410°—440° C. under the old system. At Neunkirchen 6 blast-furnaces will be worked with 15 stoves, of which not more than 12 will be running continuously. The method can also be applied to boiler firing.—A. S.

Electrolytic iron, its manufacture, properties, and uses. L. Guillet. Iron and Steel Inst., 1914. [Advance proof.]

IN the manufacture of electrolytic iron taken on a commercial scale in France, a revolving cathode is used, with a solution of iron salts kept neutral by circulation over the surface of the iron. A depolariser, such as iron oxide, is added periodically to the bath, to eliminate, at least in part, the hydrogen deposited at the cathode. It is possible to work with a current density up to 1000 ampères per sq. metre, with a yield of 2 tons of metal per kilowatt-year, including the current for accessory services, especially for the rotation of the cathode. Using pig iron containing C 2·35, Si 1·31, S 0·07 and P 1·07%, electrolytic iron containing C 0·004, Si 0·007, S 0·006, and P 0·008%, after removal of the gases by annealing has been obtained, and iron of similar quality can be obtained from any grade of pig iron. For the properties of the electrolytic iron, see this J., 1913, 290. Tubes of 100—200 mm. diam., 0·1—6 mm. thick and 4 m. long are made regularly at the rate of 100 tubes per day. A tube of 100 mm. diam. and 0·75 mm. thick, when subjected to a pressure of 1200 lb. per sq. in., was deformed permanently and uniformly as if squeezed in a press. Another specimen after being heated at 120° C. in a boiler for 2½ months withstood a pressure of 1200 lb. per sq. in. without any trace of fracture. Good results have also been obtained with sheets in laboratory trials. The metal can be easily worked and is specially suitable for the construction of electrical machinery. In consequence of the magnetic properties of the electrolytic iron and its regularity of thickness and compressive strength, its use permits of a saving in weight of material of 33—40% in transformers and 16% in direct current machines, whilst the capacity of alternating motors, running at the same temperature and occupying the same space, can be increased by 50%. The total cost of the iron as it leaves the electrolytic bath depends on cost of material and labour, but is placed at from £6 to £7 12s. per ton by the author.—A. S.

Iron; A microscopic study of electrolytic ——. O. W. Storey. Trans. Amer. Electrochem. Soc., 1914, 25, 489—527.

THE deposits of electrolytic iron were crystalline but variable in character (being fine or coarse, soft and porous or hard and dense, nodular, etc.) and frequently resembled the minerals manganite, hæmatite and limonite in structure. On heating to 910°—915° C., the crystalline structure of the deposit was converted into the grain structure of ordinary ferrite, the grain being large or small as the original deposit was coarse or fine; but no change occurred below the A_3 point. By long annealing at the Ac_3 point the coarse-grained ferrite structure became somewhat finer, but never as fine as that resulting from a fine-grained deposit. The grains of electrolytic iron did not grow appreciably at 1150° C. The ferrite grains of fused electrolytic iron were composed of smaller grains, the boundaries of the latter being merely shallow depressions whereas those of the former were V-shaped grooves; continuity of inner grain structure was observed between merging grains of similar crystal orientation, and this inner structure was only destroyed by several annealings above the Ac_3 point. The inner grains are probably groups of similarly-oriented iron crystals, the orientation in all the grains being alike throughout the ferrite grain; and the large γ grains formed during the slow cooling of the molten metal contain numerous, similarly-oriented, non-γ nuclei, and are changed to the non-γ state without altering in size. The microstructure of rolled electrolytic iron consisted of clean ferrite, and that of the forged metal of fine-grained ferrite containing a minimum of impurities.—W. E. F. P.

Steel; The oxygen content of open-hearth ——. J. A. Pickard and F. M. Potter. Iron and Steel Inst., 1914. [Advance proof.]

OXYGEN was determined by heating the steel in a confined volume of hydrogen in the presence of a weighed boat containing phosphoric anhydride (Carnegie Scholarship Memoirs, Iron and Steel Inst., 1913, 70). The results given are :—

Sample.	C %	Mn %	Si %	S %	P %	O %

he higher proportions of oxygen were present in the heaper steels (of which Nos. 8, 10, 13, 18 and 21 are xamples), and the general superiority of acid, over basic, teels may be due in some measure to its lower oxygen ontent. The high results for oxygen, in good quality teels, obtained by previous workers are discussed and he methods of analysis criticised.—W. E. F. P.

teel castings; Electric ——. C. A. Hansen. Trans. Amer. Electrochem. Soc., 1914, **25**, 133—137.

s a foundry of the Treadwell Engineering Co., Easton, a., a 3-phase arc furnace (nominal capacity 2 tons per harge) is employed, the current—supplied at 2200 volts,) cycles—is stepped down to 85 volts by means of two 0 K-V.A. transformers, and direct current motors are sed for regulating the electrodes. The foundry is perated on day-shift only, a good quality of steel scrap eing charged cold with sufficient pig and ore to keep the arge off the furnace bottom and produce a casting metal ntaining about 0·2% C (as against a minimum of 3—0·4% in ordinary crucible-steel castings); it has not en found economical to reduce the carbon content of e metal further, to preheat the furnace by means of xiliary fuel-burning apparatus, or to employ molten pola metal for charging. 15 heats per week are made, e average weight per heat being 4600 lb.; the average wer consumption is 900 kilowatt-hours, and the costs of pairs and of electrodes each $2.50 (10s. 5d.), per 2000 lb. e average weight of castings made is 9 lb.; the ratio cleaned castings, risers, etc., to charged weight, 92—95%; d the ratio of finished castings to charged weight, about %. The furnace lining is repaired after every 35 heats. —W. E. F. P.

rromanganese in steel processes; Use of molten ——. A. Sahlin. Iron and Steel Inst., 1914. [Advance proof.]

avoid the loss of ferromanganese caused by adding it the charge in the solid state, it is frequently melted in ctric furnaces; those in use have a furnace efficiency only about 44%. With the Rennerfelt furnace (this J., 12, 1188) an efficiency of 78—79% is reached if the ferro-nganese is charged into the empty previously-heated rnace, or 47% if it is dropped into an existing liquid th in the furnace. To obtain the higher efficiency e cold ferromanganese is placed upon a bridge the surface which is slightly below the highest level of the bath en the furnace is charged, or several small furnaces are d and discharged into a travelling receiver in succession. —O. E. M.

els; Transformations of ——. H. de Nolly and L. Veyret. Iron and Steel Inst., 1914. [Advance proof.]

the authors' view the transformation-point is marked the allotropic change of α- into β- or γ-iron, with a more less complete dissociation of carbide and solution of the bon liberated in γ-iron. If it be admitted that the allo-pic change involves shrinkage, and that the dissociation d solution involve dilatation, this view is supported by numerous dilatation curves given for steels of various nposition.—O. E. M.

n and steel; The brittleness produced in ——, by deforma-ion at different temperatures. G. Charpy. Comptes end., 1914, **158**, 311—314.

E brittleness of steel increases regularly with the nperature of deformation and attains a maximum, rying according to the nature of the steel, at about ° C., this temperature being coincident with that of nimum ductility, and nearly 200° below that of nimum resilience.—W. E. F. P.

el; Influence of coalescence on the mechanical properties f —— and on alloys. A. M. Portevin and V. Bernard. ron and Steel Inst., 1914. [Advance proof.]

the result of coalescence—induced by prolonged ealing—of an eutectoid steel (C 0·8, Mn 0·3, Si 0·37%), tensile strength, elastic limit and Brinell hardness were reduced, and the elongation and reduction of area increased. In the case of a hypoeutectic steel (C 0·5, Mn 0·5, Si 1·8%) the effect of liquation and coalescence phenomena upon the resilience and hardness of specimens which had been subjected to different heat treatments was determined. When heated for 10 mins. before hardening, the mechanical properties of the specimens differed according to the nature of the preliminary heat treatment, but by increasing the heating period to 30 mins. all the specimens were "restored" irrespective of their previous condition. The explanation of many experimental facts relative to the heat treatment of alloys generally may be traced to the phenomena of coalescence and liquation.—W. E. F. P.

Cobalt; Determination of —— in high-speed steels. L. Dufty. Iron and Steel Inst., 1914. [Advance proof.]

THE volumetric cyanide and gravimetric nitrite methods hitherto employed for determining cobalt in steels are liable to considerable error, but quite satisfactory results are obtained by precipitating the metal as ammonium cobalt phosphate. 3 grms. of filings are dissolved in hydrochloric acid, oxidised with nitric acid, and tungstic acid filtered off. The excess of acid is neutralised with ammonia, the iron precipitated with acetic acid and ammonium acetate and an aliquot portion of the filtrate, representing 2 grms. of steel, is acidified with hydrochloric acid, evaporated to 50 c.c., and neutralised with ammonia, the precipitate being dissolved and re-precipitated with ammonium acetate. The combined filtrates (200 c.c.) are neutralised with acetic acid and 4 c.c. excess of acid and 15 c.c. of ammonium acetate solution added. Hydrogen sulphide is passed through the solution for 15 mins., the cobalt sulphide is separated, dissolved in hot dilute nitric acid, 20 c.c. hydrochloric acid added, and after evaporation to 10 c.c., the solution is diluted and the cobalt precipitated in a volume of about 125 c.c. by adding 1 grm. of ammonium phosphate, and just enough ammonia to produce a slight precipitate, then 15 c.c. of ammonium acetate, and finally ammonia till slightly alkaline. The liquid is warmed until the flocculent blue precipitate changes to a crystalline purple-rose one. This is ignited in a muffle and weighed as $Co_2P_2O_7$. The filtrate will still contain a trace of cobalt, but this is counterbalanced by the presence of traces of iron phosphate and silica in the precipitate. If nickel is present it is separated by the dimethylgloxime method from the original acetate filtrate, and the cobalt determined as phosphate in the filtrate.—G. F. M.

Chloridizing leaching at Park City, Utah. [Recovery of copper, silver and gold from low-grade ores]. T. P. Holt. Min. and Eng. World, 1914, 383—386.

THE ore containing per ton 6—14 oz. Ag, 1—2 lb. Cu, 0·01—0·015 oz. Au, and a little Pb and Zn, is crushed, mixed with coaldust and salt, roasted by the combustion of the fuel in the charge, leached with acid salt solution, and the Ag, Cu, Au, and Pb precipitated together on scrap iron. Recently the shaft furnaces previously used for roasting have been replaced by a continuous furnace in which the column of ore moves down at intervals as the roasting zone travels upwards. The charge contains 2·4—3·0% of fuel and 7·5% of salt, and must be thoroughly mixed. The leaching solution consists of soluble salts from the roasted ore with some free acid, derived in part from the condensed roaster fumes. The product deposited on the scrap iron contains Au 1·78 oz. and Ag 6868·5 oz. per ton, Pb 13·2%, Cu 36·94%, insoluble residue 7·5%, Fe 2·5%, S 1·6%, and Zn *nil*.—A. T. L.

Copper ores; Leaching and electrolytic treatment of —— at Chuquicamata, Chile. E. A. C. Smith. Trans. Amer. Electrochem. Soc., 1914, **25**, 193—206.

THE ore deposit at Chuquicamata is probably the largest copper deposit known. It extends a distance of about 8000 ft., with an average width of 500 ft., and up to the present 200,000,000 tons of ore have been developed. The copper-bearing mineral is mainly brochantite (oxysulphate) and is readily extracted by cold dilute sulphuric acid. No deleterious impurities other than chlorine, derived from a deposit of salt in the upper parts of the ore body, are dissolved and the acid produced in depositing copper electrolytically from the solution more than suffices to make up the losses in working. Before electrolysis the chlorine is precipitated as cuprous chloride by treating the solution with copper shot placed in a revolving drum. In tests with an experimental plant of 15 tons capacity, an extraction of 90·96% of the copper was obtained. A description of the plant now in course of construction is given. The daily capacity of the plant will be about 10,000 tons of ore and that of the electrolytic refinery 335,000 lb. of copper.—A. S.

Copper ores; Hydro-electric treatment of ——. R. R. Goodrich. Trans. Amer. Electrochem. Soc., 1914, **25**, 207—242.

A REVIEW, with copious references, of the practised and suggested hydrometallurgical processes for the extraction of copper from ores, including both purely chemical and electrolytic methods.—A. S.

Zinc; Electrolytic deposition of ——. J. W. Richards. Trans. Amer. Electrochem. Soc., 1914, **25**, 281—290.

A REVIEW of electrolytic methods for the deposition of zinc. The refining of impure zinc in the absence or presence of precious metals may be commercially successful with cheap sources of power and high market values of zinc. Processes for the direct estimation of zinc in compounds, using soluble anodes containing zinc compounds or no zinc, or using insoluble anodes, but utilising or not utilising the electro-chemical reaction at the anode, have either been abandoned or are only moderately successful commercially, with the exception of direct estimation using insoluble anodes in which the electrochemical reaction at the anode is not utilised. Ordinarily zinc can only be efficiently deposited from slightly acid solutions with a low current density, but Pring and Tainton have shown that in the presence of a small amount of colloidal matter, the reverse is the case (see this J., 1914, 423).—B. N.

Zinc from zinc sulphate solutions; Addition agents in the [electro] deposition of ——. O. P. Watts and A. C. Shape. Trans. Amer. Electrochem. Soc., 1914, **25**, 291—296.

THE most promising addition agents for obtaining good electrolytic deposits of zinc were found to be eikonogen, pyrogallol and β-naphthol, the latter being the best, though gum arabic, benzoic acid, caffeine, formin, and terpin hydrate gave fair results, the most common defect being the production of vertical grooves or striations. One gram of the agent per litre was added to a solution of zinc sulphate (25% of $ZnSO_4,7H_2O$), using a zinc anode and iron cathode and a current density of about 10 amps. per sq. ft.—B. N.

Brass foundry; Safety and sanitation in the ——. F. Moerl. Amer. Inst. Metals, Sept. 7—11, 1914. [Advance proof.]

AN account of the measures adopted in a brass foundry in Chicago.

Brass melting; Electric ——. G. H. Clamer and C. Hering. Amer. Inst. of Metals, Sept. 7—11, 1914. [Advance proof.] (See also this J., 1913, 27.)

THE furnace of the Hering type, used in the tests, consists of a shell lined, so as to form a hearth, in the bottom of which are several inclined cylindrical holes, extending into the lining and terminating at their outer ends in electrodes of graphite or of the same metal as that to be melted. The current passes through the liquid metal in these holes, or resisters, squirting it out by the "pinch effect" into the mass of metal on the hearth. Suspended matter is thus removed to the top and the metal is refined. The rapid flow in the heating holes is based on the use of a heavy current of low voltage. The furnace may be made to tilt, thus facilitating direct casting into the moulds and avoiding expensive superheating. The electrodes are attached to transformers of the two- or three-phase type, which are secured to the shell, thus permitting heating during the tilting operation. The furnace is normally sealed, and opened only for pouring, the zinc loss being reduced to an almost negligible amount, as a reducing atmosphere can be maintained in the furnace.—B. N.

Zinc bronze: 2Zn-10Sn-88Cu; Standard test bars of the ——. C. P. Karr. Amer. Inst. of Metals, Chicago, Sept. 7—11, 1914. [Advance proof.]

THE most suitable conditions for pouring and moulding test bars so as to secure high and uniform tensile strength and ductility, were investigated by the U.S. Bureau of Standards. The sand cast-to-size shape is recommended as the standard form for general foundry practice, since it is easy to mould (a dry sand mould is used and the bar cast flat or vertical), inexpensive to machine to the shape and size required for testing, and gives uniformly good results irrespective of the pouring temperature. Normalised chill bars, comparable to the sand cast-to-size shape, were obtained by annealing chill cast bars between 500° and 700° C. For all types of bar, the best results were obtained by pouring between 1150° and 1270° C.
—W. E. F. P.

Nickel; Electrodeposition of ——. C. W. Bennett, H. C. Kenny and R. P. Dugliss. Trans. Amer. Electrochem. Soc., 1914, **25**, 335—346.

THE best deposits of nickel are obtained when a definite amount of ammonia is added to the solution of nickel ammonium sulphate, the efficiency being dependent upon the degree of alkalinity of the cathode film, and if the solution is vigorously stirred the efficiency is decreased. It is probable that, in acid solutions, nickel is deposited only when the impoverishment of the hydrogen ions causes the solution to become alkaline. The iron content of the anode does not materially affect the efficiency, but with a rotating cathode the iron content of the deposit is greater than that formed on a stationary one. Probably the ammoniacal film prevents the electrodeposition of the iron, except by mechanical occlusion, owing to the formation of a deposit of hydrated oxide.—B. N.

Cadmium; Electrodeposition of ——. *Part I.—Review; Part II.—Experimental.* F. C. Mathers and H. M. Marble. Trans. Amer. Electrochem. Soc., 1914, **25**, 297—333.

A HISTORICAL review of the electrodeposition of cadmium, dealing with inorganic and organic salts and with ammoniacal solutions, is given. In almost all cases, rough crystalline deposits are obtained. Experiments have shown that good and smooth deposits of cadmium may be obtained from perchlorate, fluosilicate, fluoborate and fluoride solutions, by the addition of clove oil, glue, peptone, and phloridizin.—B.N.

Lead in tinning baths and solders; Determination of small quantities of ——. P. Breteau and P. Fleury. J. Pharm. Chim., 1914, **10**, 265—273.

ONE grm. of the sample is fused with sulphur and sodium carbonate, the product digested with warm water, and the sulphides of Pb, Cu and Fe filtered off, washed with sodium sulphide solution, and dissolved in the least possible quantity of hydrochloric acid containing bromine. After boiling and reducing the Fe with sulphurous acid, the cooled solution is treated with excess of potassium cyanide, made alkaline and the Pb precipitated by sodium sulphide. The precipitate is washed with sodium sulphide solution, dissolved in warm nitric acid, the solution evaporated, the residue dried at 130°—150° C., and dissolved in 10 c.c. of water. The solution is evaporated, the residue dissolved in 5 c.c. of water together with a crystal of sodium acetate, and the solution poured into 25 c.c. of a solution containing 0·1423 grm. of $K_2Cr_2O_7$ per litre. The colloidal precipitate of normal lead chromate (a basic chromate is precipitated if the bichromate be added to the lead solution) is aggregated by shaking with 0·1 grm. of powdered asbestos, filtered off, the filtrate and washings made up to 100 c.c., and the excess of bichromate determined iodometrically.—F. Sodn.

Aluminium alloys ; A hot-shortness testing machine for ——. A. B. Norton. Amer. Inst. of Metals, Chicago, Sept. 7—11, 1914. [Advance proof.]

A test-piece 2 in. long and ½ in. diam., having each end connected (unfilleted) to the end of a cylinder 5 in. long and 1 in. diam., is cast horizontally, in sand, so that, as it contracts during solidification, it lifts a weight or cracks in the attempt. The specimen is cast, without a riser, in an iron flask, but has at the gate end a bolt which is fixed rigidly to the flask and holds the test-piece stationary when contraction begins ; tension is applied to the opposite end through another bolt (also cast in the test-piece) attached to a flexible wire cable passing over a pulley and provided with a scale pan. The largest load the alloy will raise without cracking is the figure taken for comparison ; and the results of the tests agree well with foundry experience.—W. E. F. P.

Aluminium die-castings. A. B. Norton. Amer. Inst. Metals, Chicago. Sept. 7—11, 1914. Pp. 1—7. [Advance proof.]

The difficulties in using aluminium alloys for die-castings are the high melting point, the tendency to absorb iron, the high shrinkage on solidification and the weakness developed by aluminium when burned or soaked. Iron moulds are used, constructed in sections containing loose pieces serving as cores or chills or forming projecting parts which would otherwise interfere with the opening of the mould. After assembling the mould, and heating it to the proper temperature, cooling pieces are inserted, the metal poured, and the cooling pieces removed in the proper order. The castings have a smooth finish and a fine grain, and will take a high polish. They are made up to 30 lb. in weight and are stronger than sand castings (see table) :—

	Sand castings.	Die castings.
Tensile strength	20,000	25,000
Approx. elastic limit (Stress for 0·01" elongation in 2") ..	13·000	13,000
Percentage elongation in 2" ..	1·7	3·1
Specific gravity	2·84	2·87

—A. T. L.

Aluminium and aluminium wares. Board of Trade Bulletin, No. 77. [T.R.]

May be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Electrical conduction [of metals] at high temperatures and its measurement. E. F. Northrup. Trans. Amer. Electrochem. Soc., 1914, **25**, 373—392. (See also this J., 1914, 141, 357, 358, 792.)

The author determined the resistivity in the molten state of Na, K, Hg, Cd, Pb, Zn, Sn, Bi, Sb, Cu, Al, Ag, Au, and also alloys of Na and K and brass. A change of state was always accompanied by an almost sudden change in resistivity. With metals which expand or contract on liquefaction, the resistivity was either a little more than doubled or halved respectively. With the exception of Zn, Cd and Sb, the increase in resistivity with increase in temperature was very nearly linear in the molten state, and with Na, K, Sn, Hg, Pb and Bi, the ratio of the coefficient of resistance to the coefficient of cubical expansion for the same temperature was practically the same.—B. N.

Calcium hydride ; Thermodynamics of the formation of ——. J. N. Brönsted. Z. Elektrochem., 1914, **20**, 81—83.

Combination between calcium and hydrogen occurs appreciably at 400° C., whilst at 900° C. the hydride dissociates rapidly at 0·1 atmosphere pressure. The dissociation curve was investigated between 650° and 750° C. The heat of formation of calcium hydride was deduced therefrom as 43,930 calories, and a direct calorimetric estimation gave 45,100 calories.—J. R.

The by-product coking industry and its relation to the manufacture of iron and steel. Cooper. *See* IIa.

Iron and Steel Institute. Hadfield Research Prize. See page 998

Patents.

Steel making ; Converter for use in ——. R. and J. R. Hyde, Sheffield. Eng. Pat. 16,653, July 21, 1913.

A combined cupola and converter arranged vertically. The lower, or converter, part may be tilted, raised or lowered as required.—W. E. F. P.

Iron ; Process of smelting and purifying ——. G. R. Gehrandt, Chicago, Ill. U.S. Pat. 1,110,540, Sept. 15, 1914 ; date of appl., June 14, 1913.

The ore is smelted in a blast-furnace having two series of tuyères arranged one above the other at the upper part of the crucible, so that the freshly reduced metal is subjected to horizontal and upwardly inclined blasts from the upper and lower tuyères respectively.—W. E. F. P.

Alloy-steel scrap ; Method of treating ——. P. P. Reese and E. L. Diehl, Munhall, Pa. U.S. Pat. 1,108,235, Aug. 25, 1914 ; date of appl., Feb. 7, 1911.

Steel scrap (containing Ni alone or with Cr, V and Mn) is first heated to about its melting-point by regenerative heat and then melted, by means of an electric current, in a stream of non-oxidising gases and in presence of fluxes and reducing agents.—W. E. F. P.

Ferromanganese and silicon ; Making an alloy of ——. J. C. Walker, Yonkers, N.Y. U.S. Pat. 1,109,640, Sept. 1, 1914 ; date of appl., Feb. 4, 1913.

Silica is reduced while in contact with molten ferromanganese, portions of the silicon alloy being periodically removed from the bath and replaced by ferromanganese. —W. E. F. P.

Steel ; Method of preparing —— *for painting.* G. D. Feidt, Assignor to American Chemical Paint Co., Philadelphia, Pa. U.S. Pat. 1,109,670, Sept. 8, 1914 ; date of appl., Feb. 4, 1914.

A mixture of alcohol and phosphoric acid is applied to the steel which is then rubbed with an abrasive and finally wiped.—W. E. F. P.

Metals or other fusible materials ; Formation and application of alloys or mixtures of ——. R. K. Morcom, London. Eng. Pat. 19,005, Aug. 21, 1913.

The solid (wire or rod) or molten metals (or other materials) are fed into a blowpipe whence, by the action of the blast, they are projected, as spray or dust, into a receiver (containing water or not) or against a preheated metal surface. The constituents of the alloy may form the electrodes of an arc and the latter subjected to the action of a blast. (See also this J., 1914, 925.)—W. E. F. P.

Metals from their solutions and apparatus therefor ; Electrolytic recovery of ——. U. C. Tainton and M. F. L. A. Aymard, Johannesburg, Transvaal. Eng. Pat. 19,669, Aug. 30, 1913.

The filtering body of the cathode is made of very finely-divided conducting substance spread upon a perforated conducting support, so that in the passage of the liquid under treatment through the cathode, turbulent or eddying flow takes place. The finely-divided substance, *e.g.*, graphite, may be added to the liquid so that it is deposited on the cathode during working. Three forms of apparatus are described, one with a horizontal support, a second with a vertical one, and a third with a porous carbon tube as support.—B. N.

Electroplating apparatus. J. T. Daniels, Assignor to The Hanson and Van Winkle Co., Newark, N.J. U.S. Pat. 1,108,145, Aug. 25, 1914; date of appl., March 10, 1913.

Two electrically-conductive conveyer screws are mounted on the tank, and carry electrically-conductive hangers, extending into the bath. A stationary curved transfer rod is connected with the screws, and, by means of a transfer wheel journaled on an axis perpendicular to the screws and the transfer rod and provided with transfer fingers, the hangers may be moved from one screw to the other by way of the transfer rod when the screws are turned.—B. N.

Electro-galvanising solution. G. Saccrdote, Assignor to The Metal Treating and Equipment Co., Inc., New York. U.S. Pat. 1,109,181, Sept. 1, 1914; date of appl., July 21, 1909.

A solution of a salt of the metal to be deposited, together with sulphate of iron, acetates of aluminium and manganese, free from alkali salts.—B. N.

Cobalt or nickel and copper; Process of extracting ——, from cobalt or nickel bearing copper. L. J. G. de Burlet, Hoboken, Belgium. Eng. Pat. 27,150, Nov. 25, 1913.

Silicate ore or slag is fused to extract the greater part of the copper as impure metal, then pulverised, treated with sulphuric acid of 32° B. or sp. gr. 1·285 (2500 litres per ton of material), the mass dried at 150°—200° C., treated with hot water and filter-pressed. After adding calcium carbonate to the solution to precipitate the iron and part of the copper, the remainder of the latter is removed by electrolysis, the liquid made ammoniacal, and the cobalt or nickel recovered electrolytically.—W. E. F. P.

Furnace for heat treatment of metals. W. A. Russell and J. Lord, Manchester. Eng. Pat. 3339, Feb. 9, 1914.

The horizontal heating-chamber of the furnace has an arched roof, inlets for flame or hot gas at each springer or base of the arch, and a gas outlet at the mouth, the walls being provided with studs or projections for abstracting heat from the gases.—W. E. F. P.

Tin; Process for the recovery of —— by conversion into volatile tin compounds. A. Richards, London. Eng. Pat. 8611, Apr. 4, 1914.

A mixture of the tin-bearing material with coal and sodium chloride is heated to about 800° C. in a reducing atmosphere and preferably under reduced pressure. The mixture may be agitated by means of rabbles; showered into, or against, the stream of hot, reducing gases and flame; or treated in the form of shallow layers or blocks. (See also Eng. Pats. 26,644 of 1911 and 56 of 1912; this J., 1913, 440, 821.)—W. E. F. P.

Furnace; Electric —— [for reduction of zinc ores]. A. L. J. Queneau, Jemeppe-sur-Meuse, Belgium. Eng. Pat. 10,061, April 23, 1914.

Tubular condensers of refractory material of the same cross-section throughout are grouped together in openings in the walls of the furnace with a suitable inclination towards the outside. The dimensions and number of the condensers are chosen so that they act like those of the Belgian type. The condensers have internally a circular cross-section each being closed at the outside end by a cylindrical plug, the upper part of the periphery being of a radius less than that of the interior of the nozzle so as to leave a passage for gas, and the lower part having an opening for the passage of a scraper. The condensers are arranged in superposed layers, with orifices in their walls, the upper ones delivering condensed liquid metal to the last layer from which the metal is run off. The electrodes are in the central part of the furnace, and the charge is introduced through a series of shoots in the walls, alternating with the groups of condensing tubes. The material is delivered on opposite sides of the electrodes, at such a level that it falls in a sloping manner towards the electrodes, giving a minimum of thickness around the electrodes where the reduction is most intense, and the transference of dust with the vapours is thus largely prevented.—B. N.

[Metal-heating] Furnace working-openings through which hot gases are discharged; Impts. in ——. W. S. Rockwell, New York, U.S.A. Eng. Pat. 12,270, May 18, 1914. Under Int. Conv., Aug. 15, 1913.

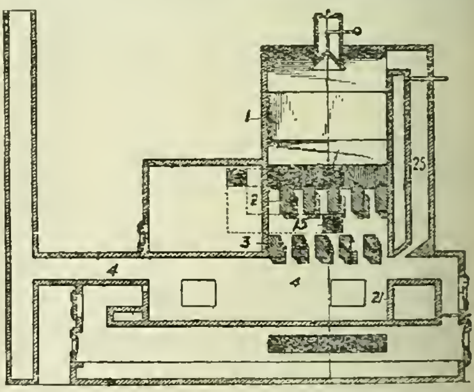
A vertical casing is fixed in front of the furnace so that the hot waste gases issuing from the working opening pass up through the casing and preheat the air for combustion which is passed through an inclined series of horizontal pipes connected at each side with a header. A sheet of non-conducting material is fixed to the front wall of the casing to protect the workmen from the heat. —W. H. C.

Smelting furnace. E. Riveroll, Los Angeles, Cal. U.S. Pat. 1,105,001, July 28, 1914; date of appl., Nov. 5, 1912

Ore is fed into an inclined chamber, the width of which increases from either end towards the middle, and which opens at its lower end into a combustion chamber above a crucible. Oil and air are supplied to the lower part of the crucible and hot products of combustion are directed across the top of the crucible and through the combustion chamber and ore chamber to a stack. As the ore is fused it flows down and collects in the crucible.—A. S.

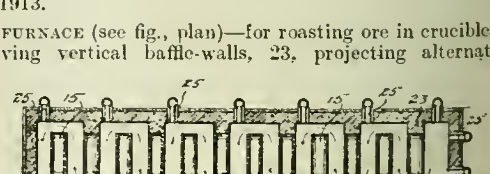
Smelting-furnace. W. E. Williams, Massillon, Ohio, Assignor to P. H. Holdsworth, Seattle, Wash. U.S. Pat. 1,108,821, Aug. 25, 1914; date of appl., Dec. 21, 1910.

The furnace (see fig.) consists of a vertical and a horizontal portion separated by two superposed sets of grate-bars, 2, 3. The horizontal portion, 4, communicates at one end with a chimney and at the other end with a down-draught flue, 25, leading from the top of the vertical part, 1. Below the horizontal portion is a slag-chamber connected with the vertical part by air-flues having branches to a heating-chamber which adjoins both portions of the apparatus.—W. F. F. P.



Ore-roasting furnace. G. P. Gibson, Braddock, Pa. U.S. Pat. 1,107,604, Aug. 18, 1914; date of appl., June 27, 1913.

A furnace (see fig., plan)—for roasting ore in crucibles—having vertical baffle-walls, 23, projecting alternately from opposite sides, and a horizontal burner, 25, adjoining each baffle wall. Removable, covered, rectangular



"crucibles," 15, which rest upon the bottom and project hrough openings in the roof, are disposed one at the nd of each baffle wall, so as to form a circuitous channel or the heating gases. Each crucible has a gas exit pipe nd also a vertical air-supply pipe extending downwards rom a common main above.—W. E. F. P.

urnace ; Ore-roasting ——. A. F. Herzig, East St. Louis, Ill. U.S. Pat. 1,108,906, Sept. 1, 1914 ; date of appl., Aug. 13, 1913.

A FURNACE of the superposed-chamber type in which the abbling mechanism is actuated from a pair of vertical hafts geared to rotate together in opposite directions rithin the apparatus.—W. E. F. P.

urnace ; Metallurgical ——. E. McCabe, Granite City, Ill. U.S. Pat. 1,109,241, Sept. 1, 1914 ; date of appl., March 13, 1914.

HE furnace consists of a hearth-chamber, each end of hich is provided with a horizontal burner (the two eing operated alternately) and connected, by a vertical own-take flue (for the passage of gas and molten slag), ith a separate air-and-gas chamber the lower part of hich communicates with a chequer-work regenerator nd is provided with a pair of catch-basins or slag eceptacles ; the latter, situated under the down-take flue nd to one side of the terminal of the regenerator, are eparated by a dividing ridge and each has an opening at he bottom through which the slag passes into a slag-pot ontained in a sealed tunnel below.—W. E. F. P.

letallurgical process. [Treating arsenicol silver-nickel-cobalt ores.] W. McA. Johnson, Hartford, Conn. U.S. Pat. 1,107,310, Aug. 18, 1914 ; date of appl., Sept. 20, 1909.

HE ore is heated in a current of moist chlorine to remove rsenic, then leached with water to extract nickel and obalt chlorides and finally treated to recover silver. —W. E. F. P.

res ; Agitator and filter for treating ——. J. D. Fields, Maxville, Mont. U.S. Pat. 1,107,922, Aug. 18, 1914 ; date of appl., Sept. 13, 1913.

HE ore is treated in a closed vertical cylindrical tank ivided into upper and lower compartments by a porous onical filter, the treating liquid being admitted from a istributor at the top of the tank and circulated by a pump hich draws it from an inclined pipe leading from the ottom of the filter. The lower compartment of the tank exhausted by an air pump. The conical filter is made f upper and lower sections joined by means of a flanged ng. The upper section makes a tight joint with a flange n the inner wall of the tank, and the lower section has a ange bolted to a central pillar in the lower compartment.—A. T. L.

letals ; Process of welding ——. J. C. Lincoln, East Cleveland, Ohio. U.S. Pat. 1,108,592, Aug. 25, 1914 ; date of appl., Jan. 21, 1913.

MINUTE quantity of a finely-divided, metallic deoxidant .g. magnesium) is applied to the surfaces of the metal .g. iron or steel) before welding.—W. E. F. P.

node residues [containing copper and precious metals] ; Process for treating ——. E. Keller, Perth Amboy, N.J. U.S. Pat. 1,110,493, Sept. 15, 1914 ; date of appl., April 17, 1913.

HE residue, freed from excess of liquid, is treated with fficient concentrated sulphuric acid to convert the pper into sulphate, the mixture (which should not be uid) heated to about 450° F. (232° C.) and then agitated th water.—W. E. F. P.

Clad metals ; Method of making ——. J. F. Monnot, Paris. Assignor to Duplex Metals Co., New York. U.S. Pat. 1,110,638, Sept. 15, 1914 ; date of appl., April 2, 1910.

THE metal (iron or steel) to be coated is passed into and withdrawn from a bath of molten metal through a layer of molten flux (sodium chloride). A further layer of the molten metal is cast upon the coating.—W. E. F. P.

[Zinc.] Process for arresting sulphurous gases and fumes and utilising the heat and gases contained therein. C. S. Vadner, Salt Lake City, Utah. U.S. Pat. 1,110,660, Sept. 15, 1914 ; date of appl., Oct. 29, 1913.

A FINELY-GROUND pulp of oxidised (or roasted sulphide) ore containing zinc and other metals is sprayed into the sulphurous gases (hot smelter fumes), and the resulting solution passed over metallic iron to eliminate copper, then oxidised, treated in the cold with sufficient finely-divided calcium carbonate to precipitate iron, arsenic, etc., filtered and heated with a further quantity of calcium carbonate to precipitate zinc as basic carbonate. The latter is re-dissolved in aqueous sulphurous acid and the solution electrolysed to recover the zinc.—W. E. F. P.

Ores ; Reduction of —— by fractional and successive meltings in a cupola. R. E. Trottier. Fr. Pat. 468,418, April 23, 1914.

AN annular partition, perforated to permit passage of gases, extends downwards from the feed hopper, a considerable distance into the shaft of the furnace. The fuel is fed into the space enclosed by the partition, whilst a mixture of the ore with fluxes and the carbon necessary for reduction is fed between the partition and the wall of the furnace. By the time the charge reaches the bosh, the lower part of which is heated to about 1200° C., the iron is practically completely reduced. In this zone the iron combines with carbon and the molten pig iron flows into an annular trough, whilst the pasty slag-forming impurities descend further into the well, heated to 1500°—1600° C. by means of additional tuyères, and are there rendered sufficiently fluid to allow of being tapped off. With a furnace of this type very friable ores, such as the minette ores of Lorraine and Luxemburg can be smelted without being previously briquetted or sintered.—A. S.

Slag ; Process of granulating molten ——. Façoneisen-Walzwerk L. Mannstaedt und Co. Act.-Ges. Fr. Pat. 469,114, Feb. 28, 1914.

THE molten slag is fed into a mechanical disintegrator into which jets of water are also injected.—A. S.

Silicon-steel. W. E. Ruder, Schenectady, Assignor to General Electric Co., New York. U.S. Pat. 1,110,010, Sept. 8, 1914. Date of appl., June 22, 1912.

SEE Eng. Pat. 11,370 of 1913 ; this J., 1914, 697.—T. F. B.

Armour-plates for warships and other steel articles ; Process of producing —— without case-hardening. A. Lucertini, Terni, Italy. U.S. Pat. 1,110,395, Sept. 15, 1914. Date of appl., April 22, 1910.

SEE Fr. Pat. 415,389 of 1910 ; this J., 1910, 1314.—T.F.B.

Metals ; Process of electrically treating, melting, and refining ——. C. A. Keller, Paris. U.S. Pat. 1,110,208, Sept. 8, 1914. Date of appl., Aug. 12, 1902.

SEE Eng. Pat. 15,271 of 1902 ; this J., 1903, 371.—T.F.B.

Alloys of tungsten and other highly-refractory metals related to it ; Method of manufacturing ——. H. Kreusler, Wilmersdorf, Germany, Assignor to General Electric Co., New York. U.S. Pat. 1,110,303, Sept. 8, 1914. Date of appl., Aug. 25, 1908.

SEE Fr. Pat. 393,595 of 1908 ; this J., 1909, 149.—T. F. B.

Zinc-furnace; Electric —— with integral condenser. C. V. Thierry, Paris. U.S. Pat. 1,110,359, Sept. 15, 1914. Date of appl., May 21, 1913.

See Fr. Pat. 456,180 of 1913; this J., 1913, 949.—T. F. B.

Solutions: Apparatus for making and filtering ——, applicable in the extraction of metals from ores and for like purposes. P. C. C. Isherwood, Bushey Heath. U.S. Pat., 1,110,790, Sept. 15, 1914. Date of appl., June 26, 1914.

See Eng. Pat. 6413 of 1913; this J., 1914, 793.—T. F. B.

Patent Cases.

Precious metal-bearing ores; Process for treating ——. A. H. Brown, Boulder, Colo. U.S. Pat. 781,711 of 1905 (this J., 1905, 242). Mining and Engineering World, Chicago, March 28, 1914, 601.

In an action brought against the Tonopah Mining Co. by Jas. A. Vincent, the U.S. District Court of Delaware found that this patent was valid and had been infringed. Brown's process treated ores, first by cyanide and afterwards by concentration, thus reversing previous practice. On appeal the U.S. Circuit Court of Appeals held that Brown's patent disclosed no new principle of operation; its substantial feature was the transposition of concentration from initial to final stage and of cyaniding from final to initial stage. The field of invention was narrow and the claims should not by construction be enlarged to include within infringing fences, processes which were not within the field of his inventive disclosure. Any process which made concentration precede final and effective cyaniding was a different one. The defendants, in common with Brown, used cyanide in the earlier stages of their process; but beyond this the resemblance ceased, for in the defendant's process concentration was the initial and intermediate step. The fruits of concentration were withdrawn and the residue afterwards treated by a protracted process of cyaniding. Thus the defendants' process, which was proved to be of great practical value, was worked in express disregard of Brown's instructions. The Court held that there was no infringement, and reversed the decree of the Court below.

Refractory metals and alloys; Manufacture of articles of ——. P. Schwarzkopf and others. Eng. Pat. 13,282 of 1912 (see Fr. Pat. 448,229; this J., 1913, 431). Reports of Patent Cases. Illustr. Off. J. (Patents), Oct. 7, 1914, 473. By permission.

The grant of this patent was opposed on the ground of anticipation and insufficient description. The Chief Examiner allowed the grant. The opponents appealed and the Law Officer allowed a patent to be granted on the Application after an amendment of the specification by way of reference to a patent No. 8031 of 1910, British Thomson-Houston Co. (see Fr. Pat. 426,299 of 1911, this J., 1911, 945, and also 946), and omission of a certain passage.

The invention related to the production of masses of tungsten, etc., by submitting to the action of a reducing gas a powder, each particle of which essentially consists of metal and oxygen in the same relative proportion; reduction was effected after consolidation of the powder by pressure in moulds; and under such conditions as simultaneously to sinter the reduced mass.

The Law Officer held that if, in a Specification of confused and complicated form, an invention that is sufficiently and fairly described can be discovered, the grant of a patent should not be refused simply because it is easy to see how much more clearly and simply the invention might have been described. He also drew attention to Eng. Pat. 4644 of 1908 (this J., 1909, 24 ref.) (see also Van Brunt, U.S. Pat. 903,922 of 1908; this J., 1909, 145).

XI.—ELECTRO-CHEMISTRY.

Electric vacuum-furnace for high temperatures. O. Ruff. Z. Elektrochem., 1914, 20, 177—179. (See also this J., 1913, 866.)

An improved form of the electric vacuum-furnace previously described (this J., 1910, 886). The heating-tube, *a*, of retort-carbon is of 4 cm. diam., and for 2000° C., 7·6 kilowatts are required, rising to 18 kilowatts for 2700° C. An additional fitting is provided which replace the upper cap, *v*, to enable a thermo-element to be introduced into the heating tube. The latter is surrounde by the fireclay cylinder, *d*, which is closed top and bottom by graphite plates, *l*, *m*, and contained in the bronze vesse *o*, cooled externally by the water-jacket, *t*. The vessel, is hermetically closed by the bronze cover, *n*, and b means of the gas tubes above and below can be exhauste as desired. An observation window, *s*, is provided the side.—G. F. M.

Electric cultivation. Löb. See XVI.

Patents.

Electrolytic apparatus. J. T. Niblett, Denmark Hi Surrey. Eng. Pat. 24,559, Oct. 29, 1913.

Hollow electrodes are arranged between an upp reservoir for the electrolyte and a lower tank for receivi the solution, the liquid being delivered on to the electrod as spray. A cooling medium, such as water, is pass successively through the electrodes. The upper a lower tanks may be in the same plane, with horizont electrodes between, or the tanks may be in differe planes, the electrodes forming an inclined plane ov which the electrolyte flows.—B. N.

Cell; Electrolytic ——. J. B. Burdett, Assignor to Davis-Bournonville Co., Chicago, Ill. U.S. Pats. (A) 1,107,257, (B) 1,107,258 and (C) 1,107,259, Aug. 18, 1914; dates of appl., (A) Oct. 29, and (B) and (C), Nov. 6, 1912.

(A) THE cover of the containing vessel carries a support, upon which inverted gas-collecting bells with bevelled mouths are suspended by means of side lugs. Each bell is arranged over an electrode and is provided with a gas-delivery pipe. (B) The inverted bells are assembled in flat-wise relationship against each other, and are provided with extended portions or fingers extending beyond the side walls. An electrode is supported within each bell, extending beyond the side walls, and porous diaphragms are interposed between adjacent bells and clamped in position between the fingers. The outer bells are provided with ears and the intermediate ones with supporting lugs at the ends, rods engaging the ears to clamp the assembled bells, whilst the clamping rods form supports for the lugs of the intermediate members. Terminal rods, passing through openings in the base of the bells, are secured to the upper edges of the electrodes, and the rods are insulated by sleeves and washers. (C) The cover of the tank is provided with integral wall portions depending from the lower surface into the electrolyte, and forming separated chambers, communicating with each other by passages in the cover. Electrodes are supported in the chamber, and co-operating electrodes in the tank, by means of suitable rods through the cover. Porous diaphragms separate the electrodes, and gas-delivery connections communicate respectively with the chambers and the tank.—B. N.

Cells; Galvanic ——. M. L. Kaplan, Brooklyn, N.Y. U.S. Pats. (A) 1,109,128 and (B) 1,109,129, Sept. 1, 1914; dates of appl., Jan. 27 and June 1, 1914.

(A) AN alkali salt of a polymanganic acid is treated with a solution of a metallic salt, so as to obtain blue neutral salts of a hydrated polymanganic acid, comprising 4 mols. of manganese dioxide to one of base, suitable as a depolarising agent. (B) Manganous polymanganite is used as the depolarising agent.—B. N.

Electrolytic cells for continuous electrolysis; Liquid supply device for ——. Ges. f. Chem. Industrie in Basel. Ger. Pat. 275,616, Aug. 17, 1913.

TROUBLE is frequently experienced in continuous electrolytic processes, owing to the shunt of the current through the stream of fresh liquid. This may be avoided by passing the liquid, on its way to the cell, through two or more superimposed vessels, each provided with intermittent siphoning arrangements.—T. F. B.

Furnace; Electric —— *and method of operating the same.* R. A. Bayard, Niagara Falls, N.Y. U.S. Pat. 1,107,478, Aug. 18, 1914; date of appl., May 27, 1913.

THE furnace consists of two movable parts, viz., a container composed of bottom and side walls, and end walls carrying the electrodes. Temporary end walls are substituted for the walls carrying the electrodes when the container is moved for charging and discharging material.—B. N.

Furnace; Electric ——. J. W. Moffat, Toronto, Canada. U.S. Pat. 1,108,924, Sept. 1, 1914; date of appl., Nov. 22, 1913.

A STATIONARY reduction chamber, opening into a stack above, is provided with an opening below, which registers with a corresponding opening in a crucible, so that when the latter is tilted connection between the chamber and crucible is cut off. Means are provided for lifting the crucible, so as to bring it into close connection with the lower part of the chamber, the crucible being also furnished with a tap hole and with electrodes extending into it from the outside.—B. N.

Chemical reactions in gases; Process of carrying out —— *by means of electric arcs.* E. Edwin, M. Hahnle, and B. Strasse, Ludwigshafen, Germany, Assignors to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,111,301, Sept. 22, 1914. Date of appl., July 3, 1913.

SEE Ger. Pat. 265,413 of 1912; this J., 1913, 1068.—T. F. B.

Method and means for electrolysing saline solutions. U.S. Pat. 1,109,311. *See* VII.

XII.—FATS; OILS; WAXES.

Olive oils extracted with carbon bisulphide; Examination of ——. F. Canzoneri and G. Bianchini. Annali Chim. Appl., 1914, 2, 1—9.

CARBON bisulphide in extracted olive oils is detected by Macagno's method of distillation with steam and testing the first portions of the distillate with a copper solution. Or, Halphen's method may be used, the distillate being shaken with amyl alcohol and kapok oil and the mixture heated at 110° C.; a pink coloration indicates carbon bisulphide. Free sulphur and sulphides are detected by placing a globule of mercury or a fragment of copper in the oil, the formation of the metallic sulphide being accelerated at 100° C. Mercaptans are invariably present in commercial oils extracted with bisulphide, and may be detected by means of mercuric chloride in the aqueous distillate. In new refining processes the proportion of sulphur compounds and the unpleasant odour are greatly reduced by treating the oil (heated to 35° to 45° C.) with low-pressure steam. The sulphur test will detect the presence of 10% of extracted oil in expressed olive oil. Colza and ravison rape oils do not give the reaction with mercury and may be distinguished from extracted olive oils by their high refractometer reading. Six samples of extracted olive oils gave the following results: Sp. gr. at 15° C., 0·9168 to 0·9198; refractometer reading at 25° C., 59 to 63·3; saponif. value, 95·6 to 95·9; Hehner value, 95·6 to 95·9; iodine value, 74·1 to 77·9; solidif. pt. of fatty acids, 17·5° to 19·7° C.; acidity (as oleic acid) 2·65 to 55·9%; ash, 0·046 to 0·056%; and total sulphur as $BaSO_4$ (4 samples), 0·4 to 0·55%. These oils differed from expressed olive oil in having a slightly higher sp. gr., a much lower iodine value, solidif. pt. of fatty acids, and refractometer reading, and a higher acetyl value (*e.g.* 31 as compared with 4·1). On extracting commercial extracted oils with carbon bisulphide 0·5 to 1·5% of a dirty white residue was obtained, largely soluble in alcohol, and in ether. It contained a wax (m.pt. 70° to 75° C.) and a resin of the type found in olive leaves, together with calcium salts of oxidised fatty acids.—C. A. M.

Chinese wood [*tung*] *oil; Examination of* ——. E. E. Ware and C. L. Schumann. Proc. Amer. Soc. for Testing Materials, 1914. [Advance proof.]

RESULTS of heat polymerisation tests (see Boughton, Proc. Amer. Soc. Test. Mats. 1913, 13, 923) are liable to variation with different observers. By the action of light on the oil an isomeric glyceride insoluble in petroleum spirit is formed, and the reaction is accelerated by the addition of a catalytic agent such as a trace of iodine or sulphur chloride. Five grms. of the oil are diluted with 25 c.c. of petroleum spirit (b.pt. 60° C.), the liquid cooled to 0° C. and mixed with 5 c.c. of chilled petroleum spirit saturated with iodine. After 1 hour's exposure to light more petroleum spirit is added, the mass left for another 3 hours, and the precipitate separated. The filtrate is chilled and again exposed to light, a little more iodine being added if necessary. The same process is repeated after the second filtration, and the final residue of unprecipitated oil (which in the case of pure Chinese wood oil averages 7%) is freed from solvent and weighed. In this way approximate determinations may be made of the quantities of other oils (*e.g.* sesamé, soya bean). Formation of iodine addition compounds (this J., 1909, 719) does not take place if sufficient petroleum spirit be added. The potassium soap of Chinese wood oil is more soluble in water than stated by Morrell (this J., 1912, 1189), but is practically insoluble in absolute alcohol, and may thus be separated from the soaps of other oils used as adulterants:—Three grms. of the sample are saponified for 30 mins. beneath a reflux condenser with 100 c.c. of *N*/4 absolute alcoholic potassium hydroxide, and the soap solution cooled for 10 mins. at 0° C. and filtered through a Gooch crucible surrounded by ice. The precipitate is washed with ice-cold absolute alcohol previously saturated with the potassium soap of elæomargaric acid, and dried *in vacuo* at 75° to 80° C. in a current of hydrogen or carbon dioxide and weighed. The weight of the dried insoluble soap may be taken as that of the wood oil in the sample. With test mixtures containing 5 to 40% of linseed and soya bean oils the results were within 1 to 2% of theory. The presence of rosin in Chinese wood oil varnish does not interfere with the heat polymerisation of the wood oil. The separated fatty acid of the polymerised oil in the varnish has twice the mol. weight of the fatty acid of the raw oil.—C. A. M.

Chinese wood oils [*and candle-nut oil*]; *Tests of* ——. Report of Committee D-1, of Amer. Soc. for Testing Materials, on Preservative Coatings for Structural Materials, 1914, 17—38. [Advance proof.]

A SAMPLE of oil expressed from the hand-picked kernels of the nuts of *Aleurites Fordii* was examined by 11 chemists with the following average results:—Sp. gr. at 15·5°/15·5° C., 0·9396; refractive index at 25° C., 1·5186; acid value, 0·9; saponif. value, 193·02; iodine value (Hübl, 18 hours), 169·6; moisture, 0·02%; ash, 0·0026%; unsaponif. matter, 0·473%; iodine-jelly test, 4 mins. 43 secs.; and heating test (Browne, this J., 1912, 731), 9 mins. 23 secs. *Iodine-jelly test*:—One grm. of oil is placed in a dish of about 6 cm. diam., which is floated on water at 25° C. The oil is dissolved in 5 c.c. of chloroform and treated (with continual stirring) with 5 c.c. of chloroform saturated at 25° C. with iodine. The stirring is continued until gelatinisation occurs and the time (usually 1½ to 2 mins.) noted. In the oxygen absorption test the maximum increase in weight was 10% after 8 days, as against an increase of 13·8% in 3 days with linseed oil. The characters of American grown tung oils agreed closely with those of Chinese oils.

Candlenut oil:—Oil extracted from the kernels of *Aleurites molucana* (yield 65·8%) had the following characters:—Sp. gr. at 15·5° C., 0·9276; refractive index at 25° C., 1·4970; acid value, 0·8; saponification value, 188·2, and iodine value, 151·6. (See also this J., 1910, 704; 1912, 782, 997.)—C. A. M.

Lubricants; *Report of Committee on standard tests for* ——. Amer. Soc. Testing Materials, 1914. [Advance proof.]

THE "Proposed Provisional Tests," of which standardised details are given, are: Viscosity test, by the Saybolt viscometer; specific gravity, by the hydrometer, Westphal balance, or Geissler pyknometer; flash and fire test, by the Cleveland open cup or Pensky-Martens apparatus; soap test; saponification-value; free acid test; sulphur test; water test; precipitation test; microscopic examination; carbon residue test. In a minority report the retention of the Engler viscometer as an alternative is recommended.—O. E. M.

Coconut and palm oil imports from Germany. Ch. of Comm. J., Oct., 1914. [T.R.]

A LARGE quantity of coconut oil was imported last year to the United Kingdom *via* Germany, namely, 210,604 cwt. of refined coconut oil, value £521,414, and 397,016 cwt. of unrefined, value £859,654. In addition 91,854 cwt. of unrefined palm oil, value £186,234, and 58,230 cwt. of refined palm oil, value £141,967, were imported *via* Germany. Rubber to the value of £269,583 was also imported in 1913 from Germany. In 1912 the exports of palm kernels from British Nigeria amounted to 184,625 tons, valued at £2,797,411, and of this quantity on
25,491 tons, valued at £365,461, were sent to Great Britai
practically the whole of the remainder going to Germar
These palm kernels are used in Germany for the p
paration of palm kernel oil and palm kernel oil-cake. T
former is largely re-exported to England, either as such
in the form or prepared cooking fats and butter substitut
The whole of this industry could well be carried on in t
country, and the palm kernel cake would form a valua
addition to the cattle feeds available to the farmer.

XIII.—PAINTS; PIGMENTS; VARNISHES RESINS.

White paints; Condition of fence coated with ——. Re t
of Committee D-1, of Amer. Soc. for Testing Materi ,
on Preservative Coatings for Structural Materials, 1 ,
62—86. [Advance proof.]

THE panels of a field fence were painted with diffe t
classes of white paints and examined after 15 mon
exposure. The paints used were:—*Primary pigme*
including three types of white lead, zinc oxide, ba -
sulphate white lead, and zinc-lead white. *Binary con* -
sitions, consisting of 80 to 50% of white lead and 20 to 5 o
of zinc oxide, basic-sulphate white lead, silica, asbest
China clay, calcium carbonate, calcium sulphate or bar n
sulphate. *Ternary compositions*, including white d
mixed with zinc oxide or basic-sulphate white lead, d
one of the other pigments in variable proportions. (-
ternary composition, consisting of equal parts of w e
lead, zinc oxide, basic-sulphate white lead, and one of e
other pigments. None of the primary paints (except
lead white) were equal to the composite paints. T y
showed fine surface cracking. In the binary and ter y
series the compositions containing zinc oxide were wl r
and cleaner and showed less cracking than paints not n-
taining it, whilst the panel painted with the quater y
composition was in better condition than any of e
others.—C. A. M.

Paint protection for Portland-cement surfaces. H. A.
Gardner. Proc. Amer. Soc. Testing Materials, 1914 4.
[Authorised reprint.]

THIRTY-FIVE samples of paint were applied to co te
surfaces and exposed in the open for 2 years. Pain o
white lead, or zinc oxide, or both, ground in pure lin
oil, or of both ground in mixtures of raw and boiled lin
oil or in treated China wood oil and thinned with tur n-
tine, in general gave good results. Paints made wit oil

varnishes containing acid resins, spirit varnishes, and glue or casein paints were unsatisfactory. When the concrete surface is damp, a zinc sulphate priming, to neutralise free lime, should be applied. Oil paints containing wear-resisting pigments were successfully applied to cement floors.—O. E. M.

White pigments ; Analysis of ——. Report of Committee D-1, of Amer. Soc. for Testing Materials, on Preservative Coatings for Structural Materials, 1914, 44—55. [Advance proof.]

Iron in lead pigments :—The sample is dissolved in nitric acid (1 : 1), the solution diluted, lead precipitated as sulphate, and iron determined colorimetrically in the filtrate by the thiocyanate method.

White lead :—*Total lead* is determined by dissolving 1 grm. of the pigment in nitric acid (1 : 1), boiling, diluting to about 120 c.c. with hot water, filtering, and adding 20 c.c. of sulphuric acid (1 : 1) to the filtrate. After evaporation till fumes appear, the liquid is diluted with 150 c.c. of water and 150 c.c. of alcohol, allowed to stand for 2 hours, filtered, and the lead sulphate washed with 95% alcohol, dried for 1 hour at 110° C. and weighed. Or the lead may be precipitated and weighed as chromate. In the absence of acetic acid or other organic matter 1 grm. of the pigment may be heated in a current of dry air (free from carbon dioxide), the water and carbon dioxide absorbed, and the residue of lead oxide weighed. The CO_2 is calculated into $PbCO_3$, and the water into $Pb(OH)_2$. For the determination of *acetic acid* Thompson's method (this J., 1905, 487) is recommended. *Metallic lead* is determined by boiling 50 grms. with 60 c.c. of 40% acetic acid, diluting the solution, decanting the clear liquid and boiling the residue with 100 c.c. of a mixture of 360 c.c. of ammonia, 1080 c.c. of water and 2160 c.c. of 80% acetic acid. This solution is also diluted and decanted, and the residue of metallic lead dried and weighed.

Basic lead sulphate :—*Moisture* is determined by heating 2 grms. of the pigment for 2 hours at 105° C. For total soluble sulphates 1 grm. is heated for 5 mins. on a steam bath with 10 c.c. of water, 10 c.c. of strong hydrochloric acid saturated with bromine, and 5 grms. of ammonium chloride, and the liquid diluted to 400 c.c., boiled for 5 mins. and filtered. Lead is removed from the filtrate by two precipitations with sodium carbonate, and sulphates precipitated from the filtrate with barium chloride. *Soluble zinc sulphate* is determined by boiling 2 grms. with 150 c.c. of water and 50 c.c. of alcohol for 30 mins., filtering, washing the residue with alcohol and water (1 : 3) and precipitating the sulphate from the filtrate. *Total lead and zinc* (*in presence of calcium and magnesium*) :—The lead is precipitated as sulphide and weighed as sulphate. The filtrate is boiled, any iron being oxidised with bromine, and iron and aluminium precipitated with ammonia. Manganese if present is precipitated by bromine water and ammonia, and weighed as Mn_3O_4. The united filtrates are acidified with acetic acid, boiled, saturated with hydrogen sulphide, treated with 5 grms. of ammonium chloride and left for 5 hours. The zinc sulphide is dissolved in hydrochloric acid and determined as phosphate. Calcium and magnesium are determined in the filtrate. *Sulphur dioxide* :—2 grms. are digested for 10 to 15 mins. with 100 c.c. of recently-boiled cold water and 5 c.c. of hydrochloric acid, an excess of 0·01 *N*-iodine solution added, and the excess titrated with thiosulphate.

Zinc white :—The loss on ignition is obtained by heating 1 grm. for 15 mins. over a Bunsen flame. Other ingredients are determined as described above.

Lithopone is analysed by the methods of Drawe (this J., 1902, 427) and Copalle (this J., 1907, 476).

Calcium pigments (*Whiting*) :—Moisture and loss on ignition are determined as above. Calcium is precipitated as oxalate and weighed as calcium oxide, and magnesium is precipitated from the filtrate. *Alkalinity* :—2 grms. are boiled for 5 mins. with 100 c.c, of water, and titrated with *N*/10 acid, with phenolphthalein as indicator. (*Gypsum*) :—Combined water and moisture are determined by heating 1 grm. for 15 mins. in a covered porcelain crucible on an asbestos plate, then for 10 mins. at a dull red heat over a Bunsen burner, and finally 30 to 40 mins. at a lower temperature until constant in weight. Soluble and insoluble constituents (in HCl), soluble sulphate, and carbon dioxide evolved on adding acid are determined by usual methods.

Barium pigments :—The determinations include moisture, loss on ignition, insoluble matter, alumina, iron oxide, etc., soluble sulphate, barium carbonate, iron (as above), and water-soluble constituents.

Silica pigments :—Insoluble matter is determined by boiling 2 grms. for 30 mins. with 50 c.c. of hydrochloric acid (1 : 1), diluting with 50 c.c. of water and filtering. It should not be less than 95%. Silica is determined by treating the ignited residue with sulphuric and hydrofluoric acids. Aluminium, iron, calcium, and magnesium are determined both in the residue and the filtrate.

China clay and asbestine :—Qualitative tests are usually sufficient. For a complete analysis 1 grm. is fused with 10 grms. of sodium carbonate (30 mins. to 1 hour), the mass treated with hot water, acidified with hydrochloric acid, and silica, barium, aluminium, iron, calcium and magnesium, carbon dioxide and soluble sulphates determined.—C. A. M.

Red lead ; Analysis of ——. Report of Committee D-1, of Amer. Soc. for Testing Materials, on Preservative Coatings for Structural Materials, 1914, 56—61. [Advance proof.]

Fineness :—10 grms. are washed with water through No. 21 silk bolting cloth and the residue dried and weighed. *Moisture* is determined as in the case of *white pigments* (see preceding abstract). *Organic colour* :—2 grms. are boiled with 25 c.c. of 95% alcohol, the liquid decanted, and the residue boiled successively with water and very dilute ammonia solution. Any coloration of the extracts indicates the presence of organic colouring matter. *Total lead and insoluble matter* :—1 grm. is heated on the water bath with 15 c.c. of nitric acid (1 : 1) and sufficient hydrogen peroxide to dissolve all lead peroxide, and the solution diluted and filtered from insoluble matter (silica, silicates, barium sulphate). The filtrate is treated with 20 c.c. of sulphuric acid, evaporated till fumes appear, and the lead sulphate determined as described under *white pigments* (see preceding abstract), and calculated to PbO. Any barium (from soluble barium compounds) in the lead sulphate is determined by digesting with acid ammonium acetate solution and weighing the insoluble residue. Calcium and magnesium are determined in the filtrate from a lead sulphide precipitation. *Lead peroxide and true red lead* (Pb_3O_4) :—Topf's modification (Z. anal. Chem., **26**, 296) of Diehl's method (Dingl. polyt. J., **248**, 196) is used, except when substances other than lead oxide, which liberate iodine under those conditions are present :—One grm. of the finely-powdered pigment is made into a smooth paste with water, and treated with a cold solution containing 30 grms. of crystallised sodium acetate, 2·4 grms. of potassium iodide, 10 c.c. of water and 10 c.c. of 50% acetic acid. After solution of the red lead the liquid is treated with 30 c.c. of water containing 5 to 6 grms. of sodium acetate, and titrated with *N*/10 sodium thiosulphate solution. The iodine equivalent of the latter multiplied by $0·94193 = PbO_2$ and by $2·69973 = Pb_3O_4$. *Water-soluble substances* :—10 grms. are digested for 1 hour on the water bath with 200 c.c. of water, the filtrate and washings evaporated and dried at 105° C. Any alkalinity is calculated as sodium carbonate. Other portions of the extract are tested for nitrates, nitrites, carbonates, sodium and lead. *Silica* :—5 grms. are digested with 5 c.c. of hydrochloric acid and 15 c.c. of nitric acid (1 : 1), the liquid evaporated to dryness, and the residue boiled with dilute nitric acid, washed successively with hot acid ammonium acetate solution, dilute hydrochloric acid and water, ignited and weighed. *Iron oxide* :—Schaeffer's colorimetric method is used (J. Ind. Eng. Chem., 1912, 4, 659). Twenty grms. of the sample are heated with 20 c.c. of water, 20 c.c. of nitric acid (sp. gr. 1·4), and 3 c.c. of formaldehyde solution until all lead peroxide has dissolved. The residue is washed with hot water, filtered off, and evaporated with sulphuric acid and hydrofluoric acid. The filtrate from the insoluble matter is treated with 14 c.c. of sulphuric acid (1 : 1) and the lead sulphate separated. The residue from the hydrofluoric treatment is dissolved in sulphuric acid, and added to the filtrate from the lead sulphate, which is then diluted to 500 c.c., and used for the colorimetric determination.—C. A. M.

Oil of turpentine; Examination of ——. Report of Committee D-1, of Amer. Soc. for Testing Materials, on Preservative Coatings for Structural Materials, 1914, 91—118. [Advance proof.]

THE following specifications applicable to oil of turpentine of all kinds are proposed:—(1) The purchaser should specify whether oil of gum turpentine or wood turpentine is required, no differentiation between the two being attempted. (2) The sample should be clear and free from suspended matter and water. (3) It should be of a standard colour. (4) The sp. gr. should fall within the limits of 0·860 and 0·875 at 15·5° C. (5) The limits for the refractive index at 15·5° C. should be 1·468 and 1·478. (6) The initial b. pt. should be 150° to 160° C. (7) 90% of the oil should distil below 170° C. (8) The polymerisation residue should not exceed 1% and its refractive index at 15·5° C. not be less than 1·500. *Methods of analysis*:—In determining the sp. gr. the factor 0·00082 should be applied for each 1° C. by which the temperature differs from 15·5° C., whilst for the refractive index the corresponding correction of 0·00045 is to be used. In the distillation test, an ordinary Engler's flask and condenser are to be used and the oil distilled at the rate of 2 drops per second. The mercury bulb of the thermometer (range from 145° to 200° C.) should be fixed opposite the side tube of the flask, with the 175° C. mark below the cork. *Polymerisation*:—20 c.c. of 38*N*-sulphuric acid are cooled (with ice-water) in a graduated Babcock flask, and 5 c.c. of the oil of turpentine slowly added with constant cooling (below 60° C.). When the reaction is over the flask is heated for about 10 mins. in water at 60° to 65° C., with occasional shaking, then cooled to the ordinary temperature, and sulphuric acid added to bring the unaltered oil into the neck. After centrifuging and standing for 12 hours its amount is read.—C. A. M.

Shellac; Analysis of ——. Report of Committee D-1, of Amer. Soc. for Testing Materials, on Preservative Coatings for Structural Materials, 1914, 119—125. [Advance proof.]

Rosin:—Langmuir's method of determination (this J., 1905, 12) is recommended as the standard test, the iodine values of shellac and rosin being taken as 18 and 228, respectively. *Insoluble test*—The method and apparatus previously described (this J., 1913, 613) are recommended for official adoption.—C. A. M.

Varnish; Quantitative determination of body and solvent in ——. A. L. Brown. Amer. Soc. for Testing Materials, June 30—July 3, 1914. [Advance proof.]

A WEIGHED quantity of the varnish is diluted to about 12 times its volume with ether, chloroform or other very volatile solvent, the solution poured over a weighed, levelled, ground-glass plate, and the latter exposed to the air or placed in a current of illuminating gas (according to the "drying" properties of the varnish) until no further loss in weight occurs; another portion of the varnish is distilled—with water (McIlhiney's method) if the solvent is gum turpentine—and the sp. gr. of the solvent determined. The percentage by volume of the solvent (x) is then calculated from the formula, $x=\frac{(100A)B}{C}$, where A is the sp. gr. of the varnish, B the percentage by weight of the solvent, and C the sp. gr. of the latter. More accurate and practical results are obtained by this method (intended primarily for insulating varnishes) than by the ordinary distillation process.—W. E. F. P.

Tests of Chinese wood oils [and candle-nut oil]. *See* XII.

PATENTS.

Pigment; Composition of matter to be used as a ——. E. Euston, St. Louis, Mo. U.S. Pat. 1,108,562, Aug. 25, 1914; date of appl., June 27, 1913.

THE pigment consists of basic zinc carbonate and lead hydroxide, "in intimate molecular combination." (See also this J., 1914, 603.)—E. W. L.

Zinc-white, Process of making ——. E. B. Cutten, Erie, Pa. U.S. Pat. 1,109,113, Sept. 1, 1914; date of appl., Sept. 15, 1913.

ZINC and any associated metals to which zinc is electropositive are converted into oxides and the latter treated at a low temperature with a suitable acid. The acid is added slowly in quantity just sufficient to combine with the zinc, the solution is then separated, and the zinc precipitated by ammonia.—W. P. S.

Varnish; Manufacture of ——. S. E. Ford, Scotia, N.Y., Assignor to General Electric Co. U.S. Pat. 1,109,979, Sept. 8, 1914; date of appl., April 4, 1913.

A LIQUID to be oxidised to form varnish is heated under oxidising conditions in a jacketed chamber provided with an agitator which divides it into a fine spray.—A. T. L.

Linseed-oil; Process for preparing substitutes for boiled ——. E. F. Waentig. Ger. Pat. 276,430, Feb. 28, 1913 Addition to Ger. Pat. 272,465 (see this J., 1914, 604).

A FISH oil or whale oil is mixed with water and a hydrolytic ferment, a small quantity of manganous sulphate is added, and the mixture is stirred at about 25° C. for some time. When partial hydrolysis has been effected, the solid fatty acids are separated and the remaining liquid is distilled by means of steam; the residue is a thick, oily product, free from acid, which may be used as a substitute for boiled linseed oil.—T. F. B.

Turpentine; Process of producing pure ——. T. W. Pritchard, Wilmington, N.C. U.S. Pat. 1,110,819, Sept. 15, 1914; date of appl., Sept. 3, 1912.

CRUDE turpentine is heated to about 212° F. (100° C.), air at the same temperature is passed through it, and the vapours are condensed.—A. T. L.

Turpentine and rosin from wood; Process of extracting ——. J. H. Castona, Gulfport, Miss. U.S. Pat. 1,111,644, Sept. 22, 1914; date of appl., Oct. 8, 1912.

MODERATELY heated turpentine is allowed to percolate downwards through the wood, the bottom of the container, and the solvent turpentine as it passes to the container, being subjected to external heat, so as to evaporate the extracted volatile elements and keep the extracted rosin liquefied. The rosin and turpentine collect in the bottom of the container and are there subjected to a higher temperature to vaporise a portion of the turpentine whilst maintaining the rosin in a liquefied condition, the residue being discharged and the unvolatilised turpentine separated from the rosin. Steam is injected internally throughout the wood, at a low temperature and pressure, to vaporise the unextracted turpentine and the retained solvent. The turpentine vapour and steam are collected and condensed and separated from the rosin.—B. N.

Insulating composition and the method of making the same. L. E. Barringer, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,111,430, Sept. 22, 1914; date of appl., May 7, 1914.

A HARD dense insulating composition is obtained by exposing a mixture, comprising linseed oil, copal gum, zinc oxide and sulphur, to the air for about 5 to 9 days, the mixture being then moulded and finally baked for several days at a temperature rising gradually about 50° to 60° C. to about 120° C.—B. N.

Emulsifying resin soap in water ; Process for ——. W. J. Dolan, Rhinelander, Wis. U.S. Pat. 1,111,689, Sept. 22, 1914 ; date of appl., April 9, 1913.

The resin soap is introduced into hot water under pressure, and then emulsified and atomised by agitating the mixture by means operated by the water pressure.—B. N.

Gelatin printing colours ; Process for preparing —— P. Charles. Ger. Pat. 276,477, April 11, 1913.

Size, or a mixture of size and glue, or a very soft glue, is ised as a binding medium for the colours. A hard glue nay be utilised for the purposes if its properties (setting oint) are suitably modified by heat or by a chemical reatment which does not affect the colours.—T. F. B.

Gelatin printing colours ; Process for preparing ——. P. Charles. Ger. Pat. 276,622, Nov. 8, 1911. Addition to Ger. Pat. 276,477 (see preceding abstract).

An alkali or alkaline-earth or ammonia is added to the gelatin solution, in the proportion of 5 to 20% on the weight of dry gelatin.—T. F. B.

Plastic composition. J. W. Aylsworth, Assignor to Condensite Co. of America, East Orange, N.J. U.S. Pat. 1,111,284, Sept. 22, 1914. Date of appl., Nov. 4, 1910.

See Fr. Pat. 435,944 of 1911 ; this J., 1912, 446.—T. F. B.

Manufacture of carbon. Eng. Pat. 6354. *See* III.

Preparing steel for printing. U.S. Pat. 1,109,670. *See* X.

XV.—LEATHER ; BONE ; HORN ; GLUE.

lue ; Specifications and tests of ——. O. Linder and E. C. Frost. Amer. Soc. Testing Materials, 1914. [Advance proof.]

pecifications for checking the quality of cabinet glue, hould be based upon the viscosity, jelly-strength, odour, eaction, grease, foaming, ash, moisture, and appearance. he glue should be clean and free from an excessive umber of air bubbles, the presence of the latter indicating ecomposition during manufacture. About 6% of ash is he permissible maximum : the quantity usually found lies etween 2·3 and 4·5%. The glue should be neutral, or ractically so to litmus paper. The jelly-strength is best scertained by steeping the glue in cold water for 16 hours nd then melting it at 160° F. (71° C.), the proportions of lue to water being such that the resulting jelly will ontain from 7 to 10% of glue (7% in the case of higher-rade glues and 10% for lower qualities). The jelly is hen cooled to about 45° F. (7° C.) and its firmness, judged y pressing with the fingers, is compared with that of a lly prepared from a standard sample. Viscosity is etermined at 30° C. in an Engler's viscometer, using a 15% lue solution ; the time of flow for a high-grade glue is bout 350 seconds. Glue should not contain any fatty ubstance, as determined by heating the glue solution ith hydrochloric acid and extracting the cooled mixture ith ether. Excessive foaming is undesirable : 300 c.c. of 10% glue solution are heated for 1 min. to 150° F. 5 C.) in a beaker of about 2·5 in. diameter, when the yer of foam produced should not exceed 0·25 in. in epth.—W. P. S.

lue from hide fleshings preserved with formaldehyde. Verein Deutscher Lederleimfabriken. Z. angew. Chem., 1914, **27**, III., 348—349.

ide fleshings bought in summer have often been found uite useless for glue manufacture. When boiled in the ue kettle they became red and hard, giving, even after rolonged boiling, a very small yield of glue of inferior uality. This has been found to be due to the use of rmaldehyde or preparations containing formaldehyde for preserving the original hides or the fleshings from them and the use of this substance is strongly condemned. —T. C.

Patents.

Leather ; Process of tanning ——. J. C. Cleary, Assignor to M. W. Borders, Chicago, Ill. U.S. Pat. 1,107,759, Aug. 18, 1914 ; date of appl., Oct. 30, 1911.

Hides are pickled, and soaked for four weeks in a liquor such as is produced by the destructive distillation of "Ouachita" cretaceous lignite, to which a tanning extract is added in about the proportion of 40 galls. of distillate to 1 lb. of extract, further quantities (3, 3, and 4 lb.) of extract being added at the beginning of the second, third, and fourth week respectively.—E. W. L.

Leather and leather goods ; Process for impregnating and preserving ——. W. Eitner and R. Kind. Ger. Pat. 276,434, July 2, 1913.

Leather is impregnated with a resinous condensation product of a phenol and an aldehyde, with or without addition of a vulcanised fat or fatty acid.—T. F. B.

XVI.—SOILS ; FERTILISERS.

Soil ; Sterilisation of ——. J. d'Agric. Prat., Apr. 23, 1914. J. Board Agric., 1914, **21**, 332. (See also this J., 1913, 1136 ; 1914, 560.)

In experiments at Rennes crops were doubled in certain cases by the use of antiseptics. Toluene, carbon bisulphide, formaldehyde and tar gave increased yields in box experiments with white mustard ; baryta, naphthol, and creosote were harmful. In field trials similar results were obtained except that copper sulphate was beneficial in the field while harmful in box experiments. When used in quantities up to 50 c.c. of liquid and 5 grms. of solid per sq. metre, the antiseptics produced harmful results except in the cases of sulphur and potassium permanganate. Toluene, carbon bisulphide, and formaldehyde up to 10 c.c. per sq. metre were beneficial ; 1 c.c. of tar was effective. Sulphur produced results proportional to the amount used. Potassium permanganate was very effective even when 5 grms. per sq. metre were used.—R. G. P.

Nitrates in soil : Relation of certain plants to the formation of ——. T. L. Lyon and J. A. Bizzell. Cornell Univ., Agric. Expt. Stat., Memoir No. 1. J. Board Agric., 1914, **21**, 440—441.

The nitrate content of soil under various crops differed for each different crop on the same soil and a characteristic relation was observed between the nitrate content of the soil and the crop at different stages of growth. The crops had also a distinct influence on the nitrate content of the soil in following years. Mixed grasses caused very low nitrate contents which may account for the known injurious effect of grass in fruit orchards where available nitrogen is deficient.—R. G. P.

Soil constituents : Assimilation of —— *by oats.* J. W. Paterson and P. R. Scott. J. Agric., Victoria, April, 1914. J. Board. Agric., 1914, **21**, 331—332.

Nitrogen, potash, lime, magnesia, phosphoric acid and silica were determined in the grain, straw and roots of oat plants (*a*) just before flowering, (*b*) when the plants were well in the ear and the lower leaves turning yellow, and (*c*) when the crop was ripening. Maximum assimilation of food constituents was reached before ripening and absorption from the soil apparently ceased some time before growth stopped. Nitrogen and potash ceased to be absorbed about the time of full bloom between stages (*a*) and (*b*). Phosphoric acid, lime and magnesia were absorbed till somewhat later : silica was absorbed as long as the plants were green. The early absorption of nitrogen and potash shows the need for a readily available supply for young oats. As phosphatic manures have a more prolonged action and are absorbed during later growth, they should be more favourable for oats than nitrogenous manures.—R. G. P.

Sodium and potassium manuring; Effect of —— on composition and yield of plants. Rhode Island Agric. Expt. Stat., Bull. 153. J. Board Agric., 1914, **21**, 441.

THE experiment was commenced in 1894 to ascertain the effect of different relative quantities of sodium and potassium applied to root crops as chloride and carbonate. Liberal amounts of nitrogen and phosphoric acid were used and lime was applied also. The full amounts of sodium and potassium applied per acre were, sodium chloride 250 lb.; sodium carbonate 220 lb.; potassium chloride 420 lb.; potassium carbonate 330 lb.; in later years about one-third of these amounts was used. Increase of sodium manures raised the amount of phosphorus but not nitrogen in the crop; the percentage of sodium in the crops was increased but the potassium generally was decreased. In most cases substitution of sodium for potassium caused a decrease in the crop. With beet-root a 25% increase in yield resulted on adding sodium manures; the percentage of total sugar in the crop was lowered, but the actual amount of sugar produced was increased. With potatoes substitution of sodium for potassium decreased their growth without altering the percentage of starch, although the nitrogen was increased.—R. G. P.

Nitrogenous manures; Experiments with new ——. E. Haselhoff. Landw. Versuchs-Stat., 1914, **84**, [1 and 2]. J. Board Agric., 1914, **21**, 332—333.

EXPERIMENTS have been made at Harleshausen during the last six years with calcium cyanamide (nitrolim), calcium nitrate, liquid manure, Schlösing nitrate (calcium nitrate containing free lime), Burkheiser salts (by-product of the Burkheiser gas-purification process), and Galalith (residue from the manufacture of a substitute for horn, etc., from casein), in comparison with ammonium sulphate and sodium nitrate, particularly with regard to time and manner of application. The utilisation of the nitrogen of ammonium sulphate was equal to that of sodium nitrate. Ammonium sulphate gave better results on loamy than on sandy soils, except when used as top-dressing for barley. Calcium nitrate was somewhat inferior to sodium nitrate, and produced a better effect on sandy than on loamy soils. Schlösing nitrate was about equal to sodium nitrate for spring wheat and barley. Calcium cyanamide applied deeply in autumn was better for barley than sodium nitrate, but if applied in autumn to the surface or in the spring either deeply or on the surface, sodium nitrate was superior. The nitrogen of calcium cyanamide was utilised better on loamy than on sandy soils. Liquid manure gave better results when mixed with the soil than when used as top-dressing. Burkheiser salts were inferior to ammonium sulphate with buckwheat or mustard, but superior to sodium nitrate with barley. Galalith gave good results on loamy soil, but was less effective on sandy soils; the nitrogen was less readily utilised than that of nitrates and much nitrogen remained in the soil for succeeding crops. (See also this J., 1913, 300.)—R. G. P.

Electric cultivation. W. Löb. Z. angew. Chem., 1914, **27**, 530—531.

EXPERIMENTS were made to determine the cause of the stimulating effect of high-tension electric discharges upon the growth of plants. The silent discharge and the glow discharge were used. Starch solutions were hydrolysed in absence of oxygen, and the portion of the starch which was not hydrolysed was rendered resistant to diastase. Peptone was slightly hydrolysed, ammonia being formed, but the amino-acids and "non-colloidal nitrogen" were not appreciably increased. The diastatic properties of pancreatin were greatly decreased, and to some extent also the tryptic properties, the action on fibrin being more strongly diminished than that on casein. The formation of sugar from starch by diastase was decreased.—J. H. J.

Egyptian phosphate industry. Ch. of Comm. J., Oct., 1914. [T.R.]

THE extensive deposits of phosphates near the Red Sea are connected by a 20-mile railway with Port Safaga on the Red Sea, where the rock is loaded and exported. The rock contains 65 per cent. or more of tricalcic phosphate. An Italian company has obtained extensive concessions about 12 miles inland from Kosseir and also at Sebaia on the eastern bank of the Nile, between Keneh and Assouan; the former concession is being linked up to the port of Kosseir with a light railway, which should shortly be completed, and the rock from the latte mines will be transported down to the Nile by a ropeway and thence to Alexandria by boat for shipment. It is expected that exports will begin that year. The total output of phosphates in Egypt for the years 1908 to 1912, according to the Survey Department, was as follows: 1908, 700 tons; 1909, 1,000 tons; 1910, 2,397 tons 1911, 11,925 tons; and 1912, 69,958 tons. According t the Financial Adviser's report, the output during 191 exceeded that for 1912 by about 33,000 tons. The Re Sea area is responsible for almost the whole output Practically all the raw phosphates produced is shippe from Egypt, principally to Japan. That country in 191 took about 49,000 tons out of a total export of 52,000 tons and in 1913 59,000 tons out of a total of 64,000 tons According to the customs returns, the average value o the raw phosphate shipped during 1913 at Port Safag was about £1 per ton. The local demand for ra phosphates for manure is practically negligible, but abou 13,000 tons of superphosphates were imported during th past year. Projects for the manufacture of superphos phates at Alexandria, with the aid of pyrites importe from Greece, are said to be under consideration, and th reported discovery of pyrites in the Sinai Peninsula is interest in view of the proximity to the Red Sea phosphat field. Should the manufacture of superphosphates b established on a considerable scale in Egypt, the workin of other deposits might become commercially possible.

The system: potassium nitrate, sodium chloride, wate Leather and Mukerji. *See* VII.

The systems: (A) water, magnesium carbonate, and ca bonic acid, and (B) water, calcium carbonate, magnesiu carbonate, and carbonic acid. Leather and Sen. *See* VI

XVII.—SUGARS; STARCHES; GUMS.

Glucose (Dextrose); Absorption of —— by bone-black. H. Morton. J. Amer. Chem. Soc., 1914, **36**, 1832—1838.

KNOWN amounts of purified bone-black and dextr solution were heated in sealed tubes at about 80° until equilibrium was established (in most cases, ab 10 days). The ratio of the weight of sugar per grm. solution to that per grm. of bone-black, after equilibri was established, was practically constant over the ent range of concentrations studied (4·63% to 50·58% dextrose). The equilibrium amount of sugar cotnained 1 grm. of the solution. At the ordinary temperatu absorption was exceedingly slow.—F. SODN.

Sugar imports from Germany. Ch. of Comm. J., O 1914. [T.R.]

THE following table shows our imports of sugar fr Germany in 1913:—

	Cwt.	£
Refined	9,309,064	6,161,
Unrefined	9,440,520	4,733,
Total value	18,749,584	10,891,

The countries whence we may expect to obtain in course supplies of cane sugar are Cuba, Java, Haiti, P Brazil, etc. A useful quantity of cane sugar is fo coming from India, British Guiana, Trinidad, and ot British West Indian Islands and Mauritius, though it hardly be expected that the output is capable of g extension at short notice.

Proposed sugar beet factory at Kidderminster. Ch. of Comm. J., Oct., 1914. [T.R.]

Difficulties in connection with the supply of machinery and beet seed having now been overcome, the Chairman of the Kidderminster Chamber of Commerce announces that a sugar beet factory will shortly be established there.

Sugar; Prohibited import and export of ——. See page 1038.

Patents.

Filter [for saccharine juice]; Continuously-operating ——. J. H. Fleetwood, New Orleans, La. U.S. Pat. 1,107,924, Aug. 18, 1914; date of appl., Mar. 24, 1914.

The saccharine juice is circulated by a pump from a reservoir, through a series of filter-casings in which the liquid flows over the outside of a number of separate filter-bags, the unfiltered liquid returning to the reservoir. The interior of the filter-bags is connected with a receiving ank fitted with a water-supply. The filter-casings are connected with a steam-supply.—A. T. L.

Sugar solutions; Process and apparatus for the clarification of ——. Köpke Clarifier Co., Ltd Fr. Pat. 467,981, Feb. 2, 1914. (See also U.S. Pat. 1,101,940, June 30, 1914; this J., 1914, 841).

The solution is introduced into a centrifugal drum through a pipe extending below a horizontal plate at the lower part of the drum, the latter having been filled previously with a charge of the solution and set in rotation. The solution which is introduced subsequently attains the velocity of the solution already in the drum before it escapes from under the outer edge of the horizontal plate; a perforated plate fitted below this horizontal plate aids n subdividing the solution. The heavier solid impurities are deposited on the wall of the drum whilst the lighter particles collect at the centre. The drum is surrounded by a casing and the process and apparatus may be used or raw, heated, defecated, or concentrated juices. Means are provided for washing and removing the separated mpurities.—W. P. S.

Sugars; Process for producing syrups and ——. C. B. Duryea, New York. U.S. Pat. 1,110,755, Sept. 15, 1914; date of appl., April 12, 1911.

Crude green starch is modified, purified, and cooked with acid; the product is neutralised, saccharified with an xtract of raw grain, refined and concentrated.—L. E.

Maltose; Process of producing ——. C. B. Duryea, New York. U.S. Pat. 1,110,756, Sept. 15, 1914; date of appl., Mar. 27, 1913.

Thick boiling starch is modified (*e.g.*, by the "in suspension" process), purified, and cooked at a concentration of about 14°—18° Bé. (sp. gr. 1·108—1·142) "under acidic onditions." The product is neutralised, saccharified by nzyme action, refined and concentrated.—L. E.

XVIII.—FERMENTATION INDUSTRIES.

Glycogen; Hydrolysis of —— by diastasic enzymes. III. Factors influencing the end-point of the hydrolysis. R. V. Norris. Biochem. J., 1914, **8**, 421—433.

A solution of glycogen is not completely hydrolysed to maltose by pancreatic glycogenase unless very high encentrations of enzyme are used, although even with low concentrations the whole of the glycogen may disppear and the liquid lose its capacity for producing a oloration with iodine. The total degree of hydrolysis produced (measured by reducing power in terms of maltose) ises with the concentration of enzyme but not proportionally After the "stationary point" has been attained. urther hydrolysis takes place on addition of more enzyme r glycogen. The activity of a glycogenase preparation is almost completely lost on dialysis, but is restored by ldition of certain salts, notably chlorides (cp. Starkenein, this J., 1910, 507). According as the quantity of salt added is large or small, so is the initial velocity and the total degree of hydrolysis produced when the enzyme is added to a solution of glycogen. After the "stationary point" has been reached, further hydrolysis can be induced by addition of more salt or more enzyme, so that there appears to be an equilibrium established between free salt, free enzyme and salt-enzyme complex. Hydrolysis is retarded by addition of the mixed hydrolytic products, but maltose alone has very little effect. It is concluded that the arrest of hydrolysis is not due to any considerable destruction of the enzyme, or to an inherent resistance of the residual dextrin to further hydrolysis, but mainly to the retarding influence of the mixed hydrolytic products.—J. H. L.

Brewing and distilling machinery and apparatus. Board of Trade Bulletin. No. 78. [T.R.]

May be obtained from the Board of Trade, Comm. Intelligence Branch, 73, Basinghall Street, E.C.

Patents.

Distilling column; High-proof, water-cooled, spirit ——. P. Publicker, Philadelphia, Pa. U.S. Pat. 1,109,701, Sept. 8, 1914; date of appl., May 9, 1914.

The column, which is submerged in a cooling liquid in a receptacle, consists of a number of superposed units, each having a concavo-convex bottom, a flat top, a concavo-convex pan above the bottom and concentric therewith, and a screen over the pan; the distillate passes through this screen before collecting in the pan. The top and bottom of the unit are braced against pressure from without, and the pan is spaced from both the bottom and the top, by brackets. The bottom of each unit is connected with the top of the unit below, and a drain pipe leads from each of the pans to a common manifold pipe. —L. E.

Producing maltose. U.S. Pat. 1,110,756. *See* XVII.

XIXa.—FOODS.

Casein; Phosphorus content of ——. A. W. Bosworth and L. L. van Slyke. J. Biol. Chem., 1914, 19, 67—71.

The phosphorus content of casein is usually given as about 0·85%, but, by treating a solution of casein in ammonia with ammonium oxalate, adding an excess of ammonia and allowing the mixture to stand for 12 hours, the phosphorus is reduced to about 0·70%. Some of the casein is hydrolysed by the treatment and some phosphorus is split off, but the hydrolysed portion is not precipitated by acetic acid and does not affect the composition of the final preparation. The higher figure ordinarily given is due to the presence of inorganic phosphorus compounds (dicalcium phosphate) derived from the milk and not removed by the usual methods of preparation. As the molecular weight of casein is approximately 8888, the lower percentage corresponds very closely with the presence of two atoms of phosphorus in the casein molecule. Analyses of various caseins show that there is a general relation between the yield of ash and the phosphorus content.—W. P. S.

Caseinogen; Action of diazomethane on ——. (Preliminary communication). A. Geake and M. Nierenstein. Biochem. J., 1914, **8**, 287—292.

Methylocaseinogen, obtained by the very prolonged action of ethereal solutions of diazomethane on caseinogen (*cp.* Herzig and Landsteiner, this J., 1914, 571), is indistinguishable in appearance from caseinogen, but contains 3·5% more methyl (in OCH_3 and NCH_3 groups) determinable by the Herzig-Meyer method. It is much less readily soluble in acids and alkalis than caseinogen, and its solution in alkalis appears to be accompanied by partial loss of methyl groups. Determinations of nitrogen in methylocaseinogen by Kjeldahl's method give consistently lower results than by Dumas' method, *e.g.*, 14·84 compared with 15·49%, yet there appears to be no evolution of free nitrogen when the substance is boiled with concentrated sulphuric acid. Methylocaseinogen gives Millon's reaction, and it is therefore doubtful whether methylation affects the tyrosin nucleus. The Adamkiewicz-Hopkins reaction is more pronounced than with caseinogen.—J. H. L.

Pentosans and methylpentosans; Production of ω-hydroxy-s-methylfurfuraldehyde from carbohydrates and its influence on the determination of ——. M. Cunningham and C. Dorée. Biochem. J., 1914, **8**, 438—447.

ω-Hydroxymethylfurfural is formed by the action of dilute hydrochloric acid on hexoses, starch and the celluloses (*cp.* van Ekenstein and Blanksma, this J., 1910, 1028). Like methylfurfural it yields a phloroglucide soluble in alcohol, and gives a red colour with solutions of aniline in alcohol, but none with aniline acetate. Owing to its slow formation it does not interfere with the determination of pentosans by the Kröber phloroglucinol method (see this J., 1901, 396) if the distillation is stopped as soon as the distillate ceases to react with aniline acetate. If, however, distillation is continued as long as the distillate produces a rose colour with an alcoholic solution of aniline, an additional large volume of distillate is obtained which yields a phloroglucide precipitate soluble in alcohol and containing ω-hydroxymethylfurfural besides methylfurfural derived from methylpentosans in the original material. If dextrose, starch or pure cellulose is subjected to acid distillation under these conditions, the distillate yields a phloroglucide precipitate entirely soluble in alcohol, and amounting to 1—2% of the material employed. Hence determinations of methylpentosans made hitherto (see Ellett and Tollens, this J., 1905, 212) are of doubtful value. ω-Hydroxymethylfurfural is probably the unknown substance precipitable by phloroglucinol, referred to by previous workers, and its presence explains many of their observations, *e.g.*, that if the distillates obtained in determining pentosans in natural products are redistilled there is often a considerable loss of "furfural" (*cp.* Fraps, this J., 1901, 843), this being doubtless due to hydrolysis of ω-hydroxymethylfurfural present, to formic and lævulinic acids, by the hydrochloric acid (see van Ekenstein and Blanksma, *loc. cit.*).—J. H. L.

Canned foods; Abnormal quantities of tin in ——. Rossée and von Morgenstern. Z. öffentl. Chem., 1914, 20, 171—172.

Canned vegetables and other foodstuffs always contain tin derived from the receptacle but, as a rule, the extent of the metallic contamination is slight. Large quantities of tin are, however, dissolved when the substance is allowed to remain in the tin after the latter has been opened. For instance, a sample of spinach contained 18 mgrms. Sn per kilo., which increased to 1038 mgrms. per kilo. when the can was left open for 6 days. A sample of canned sorrel contained 315 mgrms. Sn per kilo., whilst a sample of spinach mixed with sorrel contained 807 mgrms. per kilo. The latter sample contained 0·434% of oxalic acid. The tin forms an insoluble compound with the vegetable substances and is not re-dissolved by the gastric juice; consequently, the presence of small quantities of tin in foods is not likely to cause injury to health. Copper salts, when added to vegetables to impart a green colour to the same, also form insoluble compounds.
—W. P. S.

Feeding stuffs (*oilcake und bran*). Board of Trade Bulletin, No. 76. [T.R.]

May be obtained from the Board of Trade, Comm. Intelligence Board, 73, Basinghall Street, E.C.

Patents.

Filters [*for milk*]. W. Poupart, Twickenham. Eng. Pat. 22,709, Oct. 8, 1913.

A shallow circular domed regulating plate having perforations round the circumference to distribute the milk over the filter-cloth is provided with a heavy circumferential ring which rests on a flange formed in the funnel-shaped filtering vessel and serves to retain the filter-cloth in position.—W. H. C.

[*Milk*] *Separators; Centrifugal* ——. I. David. Fr. Pat. 468,811, May 3, 1913.

In the bowl of the separator is a spiral formed of a number of thin plates spaced very slightly apart so that a number of relatively short spiral passages are formed for the liquid. The upper surface of the compound spiral has the form of an inverted cone and follows very closely the contour which the surface of the liquid would assume if it were rotated in an empty bowl.—W. H. C.

Finely divided solid materials [*milk powder, etc.*] *suspended in air or other fluid; Recovery of* ——. Merrell-Soule Co. Fr. Pat. 468,859, Feb. 24, 1914.

The process is intended particularly for the recovery of fine powders obtained by evaporating milk or other organic liquids. The milk or the like is sprayed into a desiccating chamber along with a current of air and the resulting solid particles are collected either in the chamber itself or in a series of filter-chambers, so arranged that the powder falls from the filters on to the floor of the desiccating chamber. Each of the filter-chambers can be independently isolated to allow the powder that has collected to be shaken down. The powder from all the filter-chambers is thoroughly mixed in order to obtain a product of uniform quality.—W. H. C.

Sour-milk preparations; Production of stable, concentrated ——. F. Sauer. Ger. Pat. 276,452, May 10, 1913.

Milk containing an acid ferment, *e.g.*, yoghurt milk, is separated into its solid and liquid components; the whey, which contains lactic acid, is mixed with sucrose, evaporated to a syrupy consistency, and mixed with the curd, which contains the ferment.—T. F. B.

Butter; Process of producing renovated and artificial ——. E. B. Heller, New York, Assignor to Beatrice Creamery Co., Lincoln, Nebr. U.S. Pat. 1,109,750, Sept. 8, 1914; date of appl., Mar. 25, 1912.

Butter material (consisting of a fatty substance and a lacteal fluid) is melted *in vacuo*, washed, and then chilled and granulated *in vacuo*. The product is mixed, in absenc of air, with milk that has previously been pasteurised and inoculated with flavouring bacteria. The mixture i allowed to ripen *in vacuo*, and finally churned and worked *in vacuo*.—L. E.

Fruits; Process of treating ——. P. J. Scheuermann, St Louis, Mo., Assignor to S. G. Martin, Chicago, Ill. W. O. Bartholomew, St. Louis, Mo., and E. Schaaf, St Marys, Mo. U.S. Pat. 1,108,521, Aug. 25, 1914; dat of appl., May 24, 1909. Renewed, July 16, 1914.

Fruit is treated with air containing 2% of an oxide o nitrogen.—W. P. S.

Food for infants, invalids, and old persons; Process f preparing ——. M. F. Doming, Tappan, N.Y. U.S Pat. 1,108,555, Aug. 25, 1914; date of appl., June 1 1913.

A mixture of ground cereals, water, protein, fat, carb hydrates, and diastatic enzyme is heated until it becom flocculent.—W. P. S.

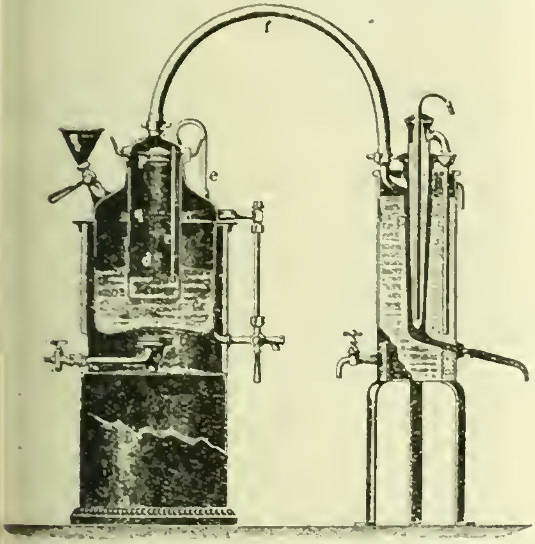
Food; Method of producing predigested ——. C. I Duryea, New York. U.S. Pat. 1,110,754, Sept. 15, 191 date of appl., Feb. 17, 1910.

A purified modified starch is cooked, then furth converted by the action of an electric current, and final refined and concentrated.—L.E.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Apparatus for the preparation and preservation of pure —— in considerable quantity. T. Paul. Z. Elektrochem., 1914, **20**, 179—185.

The general arrangement of the apparatus is shown in the diagram. Fresh spring water, freed from carbon dioxide by standing for some days with calcium hydroxide, s decanted into the tinned copper still, c, of about 30 itres capacity, and is slightly acidified with phosphoric icid. The steam passes through the tin U-tube, *e*, into he bottom of the inner vessel, *d*, also of block tin. This ontains milk of lime, and is provided with sieve plates, , *q*, to prevent calcium hydroxide blowing over into the ube, *f*, leading to the double surface condenser, *g*. The listillate is collected in well cleaned and steamed Jena lass vessels. After about 2 litres have passed over the onductivity of the condensed water should have sunk to bout $0·7 \times 10^{-6}$ and about 10 litres of distillate of high urity can then be collected. This may be further purified y bubbling through it carbon-dioxide-free air for from 4 to 36 hours, whereby the conductivity will be further educed to from $0·45 \times 10^{-6}$ to $0·5 \times 10^{-6}$. For this purpose, nd for the preservation of the water for use as required, flask of about 15 litres capacity is fitted with a rubber topper through which pass two glass tubes leading to the ottom of the flask, and a third short one connected hrough a soda-lime tube with a water pump. One of he longer tubes serves for the admission of purified air. he third tube, provided with a pinch-cock, serves for rawing off the pure water for use and for sucking up resh distillate into the flask.—G. F. M.



Arsenates of lead. Tartar and Robinson. *See* VII.

Patents.

Vater softening, purifying or filtering devices. G. R. Shankland, Manchester. Eng. Pat. 25,730, Nov. 11, 1913.

PORTABLE apparatus consists of two superimposed ylindrical vessels, the upper one containing a layer of rtificial zeolites or other filtering material through which he water flows into the lower vessel. Or, the ltering material may be contained in a vessel situated etween hte other two, and when not in use, the upper and iddle vessels may be pacfied into the lower and enclosed y a lid.—W. P. S.

Water; Method of softening ——. G. E. Bailey and B. A. Hatch, Assignors to The Ferrochem Co., Los Angeles, Cal. U.S. Pat. 1,108,514, Aug. 25, 1914; date of appl., June 15, 1912.

Solid rollers, constructed of material suitable for the softening of water, are immersed in the water and caused to rotate one against the other under pressure; the abraded particles mix with the water.—W. P. S.

Sterilising bottles; Method of ——. E. C. R. Marks, London. From The Zahm Manufacturing Co., Buffalo, N.Y., U.S.A. Eng. Pat. 9636, April 18, 1914.

The bottles are carried on an endless band through a conduit containing heated air, then immersed in water heated to 140° F. (60° C.) and filled with the same, next emptied and carried through a conduit containing cold air, and finally discharged from the band. The air current forced through the cooling conduit is led through a narrow chamber in the hot water vessel and thence into the hot air conduit.—W. P. S.

Solidified oil [Insectifuge] and process of making same. C. Ellis, Assignor to Ellis-Foster Co., N.J. U.S. Pat. 1,109,119, Sept. 1, 1914; date of appl., March 29, 1910.

An insectifugal composition consists of a mixture of pine oil, naphthalene, a small quantity of sodium stearate, and a non-volatile oil, heated together at above 100° C. to form a clear and transparent cake.—W. P. S.

Nitrogenous bases from tar or tar oils; Process for increasing the fungicidal and insecticidal properties of the ——. Chem. Fabr. Flörsheim Dr. H. Noerdlinger. Ger. Pat. 276,685, July 2, 1913. Addition to Ger. Pat. 257,848 (see this J., 1913, 479).

The bases are heated with sodium or potassium in presence of an alcohol. *Example:* 50 kilos. of coal tar bases are mixed with 180 kilos. of sodium, and 700 kilos. of absolute alcohol is added at such a rate that a brisk reaction takes place: when the addition is complete, the mixture is heated under a reflux condenser till all the sodium is dissolved and is then treated with water; 45—50 kilos. of bases of increased insecticidal powers are obtained. Other bases, such as those obtained in the dry distillation of molasses, may be treated similarly.—T. F. B.

Water; Process of softening ——. H. Ley, Assignor to Verein. Seidenfärbereien C. A. Langenbeck und I. P. Lohe, Elberfeld, Germany. U.S. Pat. 1,109,849, Sept. 8, 1914. Date of appl., Nov. 24, 1913.

See Fr. Pat. 463,044 of 1913; this J., 1914, 331.—T. F. B.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Drugs and preparations derived therefrom; Comparison of the methods used in the various Pharmacopoeias for the determination of the active principles of potent ——. H. Dichgans, Inaug. Dissert., Berne. Reviewed by H. Hérissey. J. Pharm. Chim., 1914, **10**, 238—243.

The methods compared are those of the Pharmacopœias of Austria, Belgium, Great Britain, Denmark, Spain, France, Germany, Holland, Hungary, Italy, Japan, Norway, Sweden, Russia, Servia, and the United States. The processes were tested with regard to their cheapness, rapidity, and precision. *Nux vomica.* The Keller-Fromme method is recommended for the drug. 7·50 grms. of the fairly fine powder are macerated with 50 grms. of ether, 25 grms. of chloroofrm and 5 grms. of ammonia for 30 mins. with frequent shaking. 50 grms. of the liquid are filtered through a double filter, evaporated, and the residue treated with 2 grms. of chloroform, 20 c.c. of ether and 20 c.c. of water. After the addition of 5 c.c. of *N*/10 hydrochloric acid to the solution, the excess is titrated using iodeosin as indicator. 1 c.c. of acid is equivalent to 0·0364 grm. of alkaloid. For the extract,

1·25 grms. are heated on the water bath for a short time with 10 c.c. of water. After cooling 50 grms. of ether, 25 grms. of chloroform and 3 grms. of ammonia are added and the whole shaken vigorously for 15 mins. 60 grms. are filtered off, evaporated, and the residue dissolved in 10 c.c. of chloroform and titrated after the addition of 10 c.c. of $N/10$ hydrochloric acid, 20 c.c. of ether and 20 c.c. of water. *Ipecacuanha root.*—6 grms. of the fine powder are shaken occasionally during 30 mins. with 90 grms. of ether and 5 grms. of 10% ammoniated alcohol. 75 grms. are filtered through absorbent cotton wool, evaporated, and the residue dissolved in 5 c.c. of absolute alcohol and treated with 20 c.c. of ether and 10 c.c. of water. The alkaloids are titrated with $N/10$ acid using hæmatoxylin as indicator, adding about 30 c.c. of water during the titration, and vigorously shaking after the addition of each portion of the acid. 1 c.c. of acid corresponds to 0·0241 grm. of total alkaloid. Or the same weight of drug may be treated as above with 120 grms. of ether, and 100 grms. filtered off and shaken out with 20, 10 and 10 c.c. of 1% hydrochloric acid. The acid extract is made alkaline with ammonia, shaken out with 20, 10, and 10 c.c. of ether, which is filtered, and evaporated to constant weight. For the tincture the method of the Hungarian Pharmacopœia is recommended. *Aconite root.*—The best results are obtained by the Keller gravimetric method (this J., 1895, 773) or the volumetric methods of the Russian and Swiss Pharmacopœias. The processes of the French, Russian and Swiss Pharmacopœias are recommended for the tincture. *Pomegranate bark.*—7 grms. of the moderately fine air-dry powder are shaken vigorously with 70 grms. of ether, 5 grms. of 15% sodium hydroxide solution added and the whole shaken occasionally during half an hour. The ether solution is filtered through absorbent cotton and allowed to stand after shaking with 5—10 grms. of water 50 grms. of the clear ethereal liquid are extracted first with 5 c.c. of $N/10$ hydrochloric acid mixed with 5 c.c. of water, and then twice with 10 c.c. of water. The excess of acid is titrated after the addition of 10 c.c. of ether and iodeosin as indicator, 1 c.c. of acid corresponding to 0·10475 grm. of total alkaloid. For the gravimetric process the same quantities are used, but the ethereal solution is shaken out with 20, 10, and 10 c.c. of 1% hydrochloric acid. The combined acid extracts are made strongly alkaline by the addition of sodium carbonate and shaken out with 20, 10, and 10 c.c. of chloroform. The latter solution is filtered into a tared flask, evaporated after the addition of 5 drops of hydrochloric acid, and the residue dried at 70°—80° C. 184 pts. of the hydrochlorides are equivalent to 147·5 pts. of the alkaloids. The volumetric processes of the Swiss Pharmacopœia are recommended for *belladonna* and *henbane leaves* and their preparations. Ethyl orange is a suitable indicator for the titration of hydrastine in *hydrastis root.* 7 grms. of the fluid extract of the latter are warmed in a current of air till the weight is reduced to 6 grms. After cooling 1 grm. of 12·5% hydrochloric acid is added and the whole made up to 14 grms. with water. This is shaken with 0·5 grm. of talc and 10 grms. of the liquid filtered off. The latter is then shaken for a few minutes with 4 grms. of 10% ammonia and 75 grms. of ether. The ethereal liquid is cleared by the addition of 1·5 grms. of gum tragacanth, and 60 grms. filtered into a tared flask, evaporated to dryness, and the residue evaporated three times with 5 c.c. of ether. It may be warmed with 10 c.c. of $N/10$ hydrochloric acid and the excess titrated with alkali using ethyl orange as indicator.
—F. SHDN.

Papaver orientale ; Subsidiary alkaloids of——. J. Gadamer. Arch. Pharm., 1914, **252,** 274—280. (See also this J., 1914, 885).

THEBAINE and isothebaine are accompanied in *Papaver orientale* by exceedingly small amounts of at least two non-phenolic and at least three phenolic alkaloids. The non-phenolic alkaloids consist of protopine, m. pt. 204°—205° C., and an amorphous alkaloid very soluble in organic solvents, whilst the phenolic alkaloids consist of a new alkaloid, *glaucidine*, m. pt. about 238°—239° C., $[\alpha]_D$ about +47 to +54°, giving colour reactions similar to, and apparently closely related to glaucine, and a mixture of amorphous alkaloids too small in amount to separate and characterise.—T. C.

Rhubarb root ; A Chinese——. L. Rosenthaler and K. Kiene. Ber. Deuts. Pharm. Ges., 1914, **24,** 234—243.

A NEW kind of rhubarb root has recently appeared, purporting to come from China. Anatomical and chemical examination show only slight differences, such as might be produced by differences of climate and soil, between this root and European rhaponticum root.—F. SHDN.

Green plants ; Constituents of——. *II. Volatile constituents of hornbeam leaves.* T. Curtius and H. Franzen. Annalen, 1914, **404,** 93—130. (See also this J., 1912, 706, 958.)

1500 KILOS. of hornbeam leaves were distilled in steam in portions of 15 kilos., the distillate made alkaline with baryta water and redistilled to remove barium salts of volatile acids. The distillate was then treated with freshly precipitated silver oxide and the silver salts of the acids thus produced from the aldehydes present were subsequently converted into the barium salts and separated from unchanged alcohols and ketones by again distilling. The following substances were isolated and identified :—formic, acetic and hexylenic acids with one or more higher homologues of the latter, acetaldehyde, *n*-butylaldehyde, valerylaldehyde, *αβ*-hexylenealdehyde with several higher homologues, butylene, pentylene and hexylene alcohols, and an alcohol of the formula, $C_8H_{14}O$, with one or more higher alcohols. The method previously used by the authors to detect the presence of formaldehyde in hornbeam leaves (oxidation of the volatile aldehydes with moist silver oxide and subsequent identification of formic acid, see this J., 1912, 706) has been proved to be fallacious, as methyl alcohol is also oxidised to formic acid under similar conditions.—T. C.

Flowers of Matricaria Chamomilla ; Constituents of——. F. B. Power and H. Browning, jun. Chem. Soc. Trans., 1914, **105,** 2280—2291.

22·23 KILOS. of the ground flowers of *Matricaria Chamomilla* Linné (German chamomile) were completely extracted with hot alcohol, the alcoholic solution concentrated to a soft extract and then distilled in steam. 23 grms. of a deep blue essential oil distilling over a wide range of temperature, together with an aqueous extract and an oily resin were thus obtained, and were separately examined The following substances were isolated and identified :—salicylic acid ; an acid, probably $C_8H_{16}O_2$, apigenin $C_{15}H_{10}O_5$, and a glucoside of apigenin which could not be obtained crystalline ; umbelliferone methyl ether $C_{10}H_8O_3$, and a crystalline substance, m. pt. 237°—239° C. which was apparently a mixture of umbelliferone and dihydroxycoumarin ; choline ; triacontane ; a phytosterol $C_{27}H_{46}O$, a phytosterol glucoside, $C_{33}H_{56}O_6$; palmitic stearic, cerotic, oleic, linolic and volatile fatty acids together with a sugar yielding *d*-phenylglucosazone There are considerable differences between the constituents of German chamomile and Roman or Englis chamomile, *Anthemis nobilis* (see this J., 1914, 885).—T. C

Cotton-root bark [Gossypium herbaceum] ; Chemica examination of——. F. B. Power and H. Browning jun. Pharm. J., 1914, **93,** 420—423.

A CONCENTRATED alcoholic extract of cotton-root bar distilled in steam yielded a very small amount of essentia oil, which gave the furfural colour reaction and deposite crystals of acetovanillone, m. pt. 112°—114° C. Th aqueous liquid from the steam distillation and the resi insoluble in water were examined separately. The follow ing substances were isolated and identified :—a phenoli acid, m. pt. 196°—199° C., probably 2.3-dihydrox benzoic acid, salicylic acid, a new *phenolic substanc* $C_9H_{10}O_3$, m. pt. 258°—260° C., giving an acetyl derivati of m. pt. 152° C., a new *yellow phenolic substance*, $C_{13}H_{18}O$ m. pt. 210°—212° C., giving an acetyl derivative of m. p

147°—149° C., betaine, a fatty alcohol, $C_{20}H_{42}O$, m. pt. 77·5°—78·5° C., a phytosterol, a small amount of hydrocarbon probably triacontane, ceryl alcohol, a mixture of fatty acids, chiefly oleic and palmitic acids, and a considerable quantity of sugar, yielding *d*-phenylglucosazone. The bark contains no tannin and no alkaloid.—T. C.

Cholin; Some new physiologically active derivatives of ——. A. J. Ewins. Biochem. J., 1914, **8**, 367—373. (See also this J., 1914, 664.)

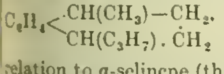
For purposes of comparison with natural muscarin from *Amanita muscaria*, the author prepared eighteen derivatives of cholin, of which the following are new:—formylcholin, $HO{\cdot}N(CH_3)_3{\cdot}CH_2CH_2O{\cdot}OCH$, cholin propyl ether, $HO{\cdot}N(CH_3)_3{\cdot}CH_2CH_2O{\cdot}C_3H_7$, cholin ether, $[HO{\cdot}N(CH_3)_3{\cdot}CH_2CH_2]_2O$, trimethyl-$\beta$-cyano- (and amino-) ethylammonium hydroxide, $HO{\cdot}N(CH_3)_3{\cdot}CH_2CH_2{\cdot}CN$ and $HO{\cdot}N(CH_3)_3{\cdot}CH_2CH_2{\cdot}NH_2$, dimethyl oxazolium hydroxide, $HO{\cdot}N(CH_3)_2{\cdot}CH_2CH_2{\cdot}OCH_2$, and formocholin methyl, ethyl, propyl and butyl ethers, $HO{\cdot}N(CH_3)_3{\cdot}CH_2OR$. All the bases prepared showed considerable physiological activity, those approaching most nearly to muscarin being cholin ethyl ether, cholin nitric acid ester, and trimethyl-β-aminoethylammonium hydroxide. The curare-like action of all these is however more pronounced than in the case of natural muscarin. The ethers of formocholin exert a physiological action similar to, but less powerful than that of the corresponding cholin ethers. The preparation and properties of the new compounds are described.—J. H. L.

Geranium oil; Production of ——. D. R. Mason. Amer. Perfumer and Essent. Oil Rev., 1914, **9**, 192. (See this J., 1913, 1127.)

The geranium rosat was taken from South Africa to France about 1690. It was first cultivated for the oil at Grasse in 1847 and taken to Algeria in the following year. Although the French oil is superior, it can be produced more economically in Algeria, as the rosat has to be planted annually in France. It should be possible to grow it in Southern California in localities not subject to severe frost. Cuttings packed for shipment can be obtained at Algiers at about 12s. to 16s. per 1000.—F. Shdn

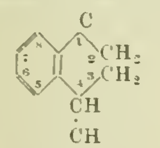
Benzoterpenes; Experiments on the synthesis of the ——. *Part I. Derivatives of benzonor-p-menthane.* F. W. Kay and A. Morton. Chem. Soc. Trans., 1914, **105**, 1565—1583.

The term "benzoterpene" is used to describe those aromatic, terpene-like substances which contain a benzene nucleus condensed to the normal monocyclic terpene skeleton such as is present in dipentene, for example. The benzoterpenes form a connecting link between naphthalene and the sesquiterpenes, benzo-*p*-menthane,



$$C_6H_4<\begin{matrix}CH(CH_3)-CH_2\\CH(C_3H_7).CH_2\end{matrix}$$

for example bearing the same relation to *a*-selinene (this J., 1913, 107) as *p*-cymene does to the monocylic terpenes in general. The preparation of a number of derivatives of benzonor-*p*-menthane,



is described. Tetrahydro-*a*-naphthoic acid, obtained by reducing *a*-naphthoic acid with sodium in boiling alcoholic solution was treated with phosphorus pentachloride and then with bromine and the resulting *a*-bromo-acid converted into its ethyl ester. The latter was boiled with diethylaniline, whereby hydrogen bromide was eliminated and a good yield of ethyl Δ^1-dihydro-*a*-naphthoate obtained. This was treated with an ethereal solution of magnesium methyl iodide and gave a good yield of benzo-Δ^3-nor-*p*-menthen-10-ol, a crystalline solid, m. pt. 101°—102° C., having a peculiar penetrating odour resembling that of naphthalene. When digested with potassium pyrosulphate it loses water and is converted into benzo-$\Delta^{3-10\,11}$-nor-*p*-menthadiene, an oil, which distils at 255°—256° C. at 750 mm. and has a pronounced odour resembling that of petroleum. Ethyl tetrahydro-*a*-naphthoate when left in contact with an ethereal solution of magnesium methyl iodide is gradually converted into benzonor-*p*-menthan-10-ol, a viscid oil having a camphoraceous odour, which distils at 166° C. at 30 mm., and when digested with potassium pyrosulphate loses water, with formation of benzo-Δ^{10-11}-nor-*p*-menthene, b. pt. 259°—261° C. at 745 mm., which has a pronounced odour recalling that of cedrene. Benzo-Δ^{10-4}-nor-*p*-menthene, b. pt 245°—247° C. at 744 mm., was obtained by reduction of benzo-$\Delta^{3-10\,11}$-nor-*p*-menthadiene with sodium and alcohol.—A. S.

Catechol; Compounds of —— *with alkali salts of carboxylic acids.* R. F. Weinland and W. Denzel. Ber., 1914, **47**, 2244—2252.

Catechol forms with the alkali salts of organic acids additive compounds, of which those with the formates acetates, succinates and salicylates of sodium and potassium have been prepared and isolated in crystalline form. They were obtained directly from the aqueous or alcoholic solutions of their components. A number of different compounds were produced from the same alkali salt, as for example $H.COONa+C_6H_4(OH)_2+H_2O$; $H.COONa+2C_6H_4(OH)_2$; $COOK.CH_2.CH_2.COOK+3C_6H_4(OH)_2+4{\cdot}5H_2O$; and $COOK.CH_2.CH_2.COOK+5C_6H_4(OH)_2+H_2O$. Only one salicylate compound was prepared; it contained 1 mol. of each component and 1 mol. H_2O.—G. F. M.

Diacetates and glycols; Preparation of —— *from dibromides.* E. G. Bainbridge. Chem. Soc. Trans., 1914, **105**, 2291—2302.

Ethylene dibromide and trimethylene dibromide when heated with potassium or silver acetates and glacial acetic acid give the corresponding glycol diacetates; propylene dibromide similarly treated gives a mixture of the glycol diacetate and an unsaturated bromide, $CH_3CH:CHBr$, with elimination of hydrobromic acid, whilst *iso*-butylene dibromide gives an unsaturated bromide and no diacetate. The diacetates of ethylene-, trimethylene-, propylene-, $\alpha\gamma$-butylene- and ω-butylene-glycols give good yields of the corresponding glycol on boiling with an equimolecular quantity of sodium ethoxide in alcohol, distilling off the solvent, saturating the residue with carbon dioxide, then boiling with 2 molecular proportions of water and fractionally distilling. Ethylene- and trimethylene-glycol diacetates are catalytically hydrolysed by boiling with very small amounts of sodium ethoxide in alcoholic solution and also by boiling with alcoholic sodium hydroxide, the yield being however adversely affected by presence of water.—T. C.

Partial pressures of liquid mixtures; Rapid laboratory method of measuring the ——. M. A. Rosanoff, C. W. Bacon, and R. H. White. J. Amer. Chem. Soc., 1914, **36**, 1803—1825.

The liquid is fractionally distilled in such a way as to avoid reflux condensation and then the composition and weight of each fraction is determined and the composition of the successive added distillates plotted against their weights, so as to obtain by extrapolation, the composition of the distillate when its weight is zero (that is, of the first trace of vapour given off by the liquid). The distillation is effected by an electric heater which is immersed in the liquid in a jacketed vessel supported in a constant-temperature bath. The vapour passes downwards through the jacket to a condenser, and thence to a receiver having compartments for the collection of consecutive fractions. The distillates are analysed by determination of the refractive index or, for ternary mixtures, by Schulze's method (J. Amer. Chem. Soc., 1914, **36**, 498). Results and curves are given for mixtures of carbon bisulphide and carbon tetrachloride, chloroform and toluene, acetone and toluene, and ethyl iodide and ethyl acetate.—F. Sodn.

Para-oxyarylarsinic acids, nitro-oxyarylarsinic acids, and 3.3′-diamino-4.4′-dioxyarsenobenzene; Applications to suspend patents for ——. Illus. Off. Journal (Patents), Sept. 9 and Oct. 21, 1914.

Mr. H. S. Wellcome has been granted a licence under the Patents, Designs, and Trade Marks (Temporary Rules Acts), 1914, to work patents for the manufacture of the above arsenic compounds (Meister, Lucius, und Brüning. Eng. Pats. 13,485 of 1910, 5595 of 1911, and 7865 of 1912; see this J., 1911, 155, 768; 1912, 900).

Synthetic drugs, new remedies, photographic developers, etc.; Index list of trade names of ——. Compiled chiefly from *The Extra Pharmacopoeia*, W. H. Martindale and W. W. Westcott, 15th Ed., 1912; *Die Arzneimittel-Synthese*, S. Fränkel, III. Aufl., 1912; *Synthetic Drugs or Medicinal Products*, V. Coblentz, in Thorpe's *Dict. of Appl. Chem*, 1913, Vol. V., 357—380; and *Merck's Index*, III. Aufl., 1910.

The following is a supplement to the list published in this Journal, 1900, pages 1131 to 1138.

Abanone.—Magnesium phosphotartrate.

Acetomorphine.—Diacetylmorphine,

$$C_{17}H_{17}NO_3(C_2H_3O)_2.$$

Acetopyrin.—Antipyrine acetylsalicylate,

$$C_{11}H_{12}N_2O,C_2H_3O.OC_6H_4.COOH.$$

Acetosal.—Acetylsalicylic acid, $C_2H_3O.OC_6H_4.CO_2H$.

Acetozone.—Mixture of equal parts of acetyl-benzoyl peroxide, $C_6H_5CO.O.O.C_2H_3O$, and kieselguhr.

Acetysal. See acetosal.

Acidol.—Betaine hydrochloride, $C_5H_{11}NO_2,HCl$.

Acitrin.—2-Phenylquinoline-4-carboxylic acid ethyl ester, $C_9H_5N(C_6H_5)CO_2C_2H_5$.

Acopyrin. See acetopyrin.

Adalin.—Bromodiethylacetylurea,

$$(C_2H_5)_2CBr.CO.NH.CO.NH_2.$$

Adamon.—Dibromodihydrocinnamic acid bornyl ester, $C_6H_5(CHBr)_2CO_2C_{10}H_{17}$.

Adigan.—Digitalis preparation containing all the active principles except digitonin, this having been removed by precipitation with cholesterol in alcoholic solution.

Adrenal.—Crystalline base from the suprarenal gland.

Adrenaline.—*o*-Dihydroxyphenylmethylaminomethylcarbinol hydrochloride,

$$(HO)_2C_6H_3.CH(OH).CH_2.NH(CH_3),HCl.$$

Adreucaine. See eudrenine.

Afridol.—Sodium salt of hydroxymercury-o-toluic acid,

$$CH_3.C_6H_3(CO_2Na)HgOH.$$

Agnin.—Adeps lanæ or purified wool fat.

Agnolin. See agnin.

Agobilin.—Strontium cholate mixed with small quantities of strontium salicylate and diacetylphenolphthalein.

Agurin.—Addition product of theobromine-sodium and sodium acetate, $C_7H_7N_4O_2Na,C_2H_3O_2Na$.

Albargin.—Gelatose-silver (15% Ag).

Aldoform.—A formaldehyde preparation.

Aleudrin.—Carbamic acid ester of *αα*-dichloroisopropyl alcohol, $(CH_2Cl)_2.CH.O.CO.NH_2$.

Alformin.—16% solution of basic aluminium formate,

$$Al_2(OH)_2(HCO_2)_4.$$

Alginoid iron. See algiron.

Algiron.—Iron compound of alginic acid (from seaweed); contains 11% Fe.

Allmatein.—Condensation product of hæmatoxylin and formaldehyde, $CH_2O_2(C_{16}H_{12}O_5)_2 : CH_2$.

Allosan.—Santalyl allophanate, $NH_2.CO.NH.CO_2.C_{15}H_{23}$.

Alphogen.—Succinyl peroxide, $(COOH.CH_2.CH_2.CO)_2O_2$.

Alphozone. See alphogen.

Althein.—Asparagin, $C_2H_3(NH_2)(CO_2H)CO.NH_2+H_2O$.

Alypin.—Benzoyl-1.3-tetramethyldiaminoethyl-2-isopropyl alcohol hydrochloride,

$$C_6H_5CO.O(C_2H_5)C[CH_2.N(CH_3)_2]_2,HCl.$$

Amarin.—Triphenyldihydroglyoxaline,

$$\begin{matrix} C_6H_5.C.NH \\ C_6H_5.\ddot{C}.NH \end{matrix}\!\!>CH.C_6H_5.$$

Amenyl.—Methylhydrastimide hydrochloride,

$$CH_2O_2 : C_6H_2(CO)_2N(CH_3),HCl.$$

Amidopyrin.—Dimethylaminoantipyrine,

$$C_{11}H_{11}N_2O.N(CH_3)_2.$$

Amphotropin.—Hexamethylenetetramine camphorate,

$$(C_6H_{12}N_4)_2,C_8H_{14}(COOH)_2.$$

Amylarine.—Isoamyltrimethylammonium hydroxide,

$$C_5H_{11}(CH_3)_3N.OH.$$

Anæsthesin.—Ethyl ester of *p*-aminobenzoic acid.

$$NH_2.C_6H_4.CO_2C_2H_5.$$

Anæsthone. See anæsthesin.

Analutos.—See kalmopyrin.

Angioneurosin.—Nitroglycerin, $C_3H_5(O.NO_2)_3$.

Anisotheobromine.—Addition product of theobromine-sodium and sodium anisate,

$$C_7H_7N_4O_2Na,C_6H_4(OCH_3)CO_2Na.$$

Anogon.—Mercury salt of 2.6-di-iodophenol-4-sulphonic acid, $C_6H_2I_2(OHg)(SO_3Hg)$.

Antacedin.—Calcium saccharate.

Anthrosol.—Coal tar distillate having colour and consistence of olive oil.

Antiarthrin.—Condensation product of saligenin and tannin, probably the hydroxybenzyl ester of tannic acid.

Antileprol.—Purified chaulmoogra oil.

Antiluetin.—Potassium-ammonium antimonyltartrate, $[SbO(C_4H_4O_6)_2KNH_4]_2H_2O$.

Antiperiostin.—Mercury iodocantharidate,

$$C_8H_{11}IO(COO)_2Hg.$$

Antipyoninum.—"Neutral" sodium tetraborate, prepared by fusing together borax and boric acid.

Antisclerosine.—Mixed inorganic salts of normal blood.

Antodin.—Phenyl ether of glycerol, $C_2H_5(OH)_2O.C_6H_5$

Aperitol.—Mixture of equal parts of isovaleryl- an acetyl-phenolphthalein.

Aponal.—Amyl carbamate, $NH_2.COOC_5H_{11}$.

Appallagin.—Mercury compound of nosophen (tetra iodophenolphthalein).

Apyron.—Lithium acetylsalicylate, $C_2H_3O.OC_6H_4.CO_2L$

Archibromin.—Monobromoisovalerylglycolylurea,

$$CH_2(OH).CO.NH.CO.NH.CO.C_4H_8Br.$$

Archiodin.—Monoiodoisovalerylglycolylurea.

Argaldin.—Combination of albumin-silver and hexa methylenetetramine (10% Ag).

Argoferment.—Colloidal silver.

Argyrol.—Silver-vitellin (20—30% Ag).

Argulan.—Mercury compound of dimethylpheny pyrazolonesulphamine, $C_{11}H_{11}N_2O.NH.SO_3HgOH$.

Arhéol.—Santalol, $C_{15}H_{24}O$.

Arhoin.—Addition product of diphenylamine and ethy thymyl-benzoate, $(C_6H_5)_2NH,C_{10}H_{13}.C_6H_4.CO_2C_2H_5$.

Aristochin. See aristoquinine.

Aristoquinine.—Carbonic ester of quinine,

$$CO(OC_{20}H_{23}N_2O)_2.$$

Arrhenal.—Sodium methylarsinate,

$$AsO(CH_3)(ONa)_2,6H_2O.$$

Arsacetin.—Sodium *p*-acetylaminophenylarsinate,

$$C_2H_3O.NH.C_6H_4AsO(ONa)(OH),3\text{–}4H_2O.$$

Arsacetin-quinine.—Contains 43% of arsacetin a 54% of quinine.

Arsalyt.—Bismethylaminotetra-aminoarsenobenzene.

Arsamin. See atoxyl.

Arsan.—Glidin preparation containing silver.

Arsanilic acid.—*p*-Aminophenylarsinic acid,

$$NH_2.C_6H_4AsO(OH)_2.$$

Arsen-phenol-amine. See salvarsan.

Arterenol.—*o*-Dihydroxyphenylaminomethylcarbinol hydrochloride, $(HO)_2C_6H_3.CH(OH).CH_2NH_2.HCl$.

Asiphyl. See asyphil.

Aspirin, Soluble.—See kalmopyrin.

Aspirophen.—Aminoacetphenetidide acetylsalicylate,

$$C_2H_3O.C_6H_4.NH.C_2H_2O.NH_2,C_2H_3O.OC_6H_4.COOH.$$

Asquirrol.—Mercury dimethoxide, $(CH_3O)_2Hg$.

Astrolin.—Antipyrine methyl-ethyl-glycollate.

Asurol.—Addition product of mercury salicylate and sodium aminohydroxy-isobutyrate.

Asyphil.—Mercury salt of atoxyl,

$$(NH_2C_6H_4.AsO.(OH)O)_2Hg.$$

Atophan.—2-Phenylquinoline-4-carboxylic acid,

$$C_9H_5N(C_6H_5)COOH.$$

Atoxyl.—Sodium *p*-aminophenylarsinate,

$$NH_2.C_6H_4.AsO(OH)(ONa),xH_2O.$$

Atrinal.—Atropinesulphuric acid, $C_{17}H_{23}O_6NS$.

Atyrosyl. See asyphil.

Azovernin.—Acetylaminoazotoluene,

$$CH_3.C_6H_4.N_2.C_6H_3(CH_3).NH.C_2H_3O.$$

Barbitone.—See veronal.

Barutin.—Addition product of theobromine-barium and sodium salicylate.

Benzinoform.—Carbon tetrachloride.

Benzosalin.—Methyl benzoyl salicylate,

$$C_6H_4(O.CO.C_6H_5)COOCH_3.$$

Biogen.—Magnesium peroxide.

Biolactyl.—Preparation of lactic acid bacilli.

Bisciniod.—Combination of cinchonidine hydriodide and bismuth iodide, $C_{19}H_{22}N_2O,HI,BiI_3$.

Bismon.—Colloidal bismuth.

Bismutose.—Contains about 22% Bi and 66% albumin.

Blankit.—Sodium hydrosulphite.

Blenal.—Carbonic acid ester of santalol, $CO(OC_{15}H_{23})_2$.

Bornyval.—Bornyl isovalerate, $C_4H_9CO.O.C_{10}H_{17}$.

Bornyval, New.—Bornyl isovaleryl glycollate,

$$C_4H_9COOCH_2.COOC_{10}H_{17}.$$

Boroform.—Solution of formaldehyde in sodium glyceroborate.

Borsalyl.—Sodium borosalicylate.

Bororertin.—Hexamethylenetetramine triborate,

$$C_6H_{12}N_4,3HBO_2.$$

Bromeigon.—Albumin preparation containing bromine.

Bromelia, cryst.—β-Naphthyl ethyl ether, $C_{10}H_7.O.C_2H_5$.

Brometone.—Tribromo tertiary butyl alcohol,

$$CBr_3.C(CH_3)_2OH.$$

Brominol.—Brominated sesamé oil (33% Br).

Brominoleum. See brominol.

Bromochinol.—Acid dibromosalicylate of quinine, $C_{20}H_{24}N_2O_2,2C_6H_2Br_2(OH)COOH$.

Bromoglidin.—Wheat gluten preparation containing 10% Br.

Bromogluten.—Vegetable albumin preparation containing 8% Br.

Bromolein.—Brominated unsaturated fatty acids of almond oil (20% Br).

Bromoprotein. See bromogluten.

Bromotan.—Bromotannin-methylene-urea.

Bromural.—α-Bromoisovalerylurea,

$$C_4H_8Br.CO.NH.CO.NH_2.$$

Brophenin.—Bromoisovalerylphenocoll; a brominated phenetidine derivative.

Brovalol.—Bornyl bromovalerate, $C_4H_8Br.COO.C_{10}H_{17}$.

Bynin.—Liquid malt extract.

Cacodyliagol.—Guaiacol cacodylate,

$$(CH_3)_2AsO.O.C_6H_4(OCH_3),H_2O.$$

Cajuputol.—Cineol (eucalyptol), $C_{10}H_{18}O$.

Calcidine.—Calcium iodide.

Calcinol.—Calcium iodate.

Calcusol.—Effervescent preparation of potassium bicarbonate and piperidine-*p*-sulphamine benzoate,

$$SO_2(NH_2)C_6H_4COOH,C_5H_{11}N.$$

Calomelol.—Colloidal calomel.

Camphoid.—Collodion substitute; 1 part of pyroxylin in 20 parts each of camphor and absolute alcohol, by weight.

Camphoral.—Camphoric acid ester of santalol,

$$C_8H_{14}(COO)_2(C_{15}H_{23})_2.$$

Camphosan.—Solution of 15 parts of camphoric acid methyl ester in 85 parts of santalol.

Canadol.—Light petroleum spirit, sp. gr. 0·650—0·700.

Casumen.—Soluble form of casein ("flocculent casein"); contains 90% of protein.

Celloidin.—Pyroxylin purified by solution in alcohol and ether.

Cellotropin.—Benzoic ester of arbutin,

$$C_6H_4OC_6H_{11}O_5.O.COC_6H_5.$$

Ceredine.—Special dry powdered yeast.

Cerolin.—Solid extract of yeast, containing fat

Cetiacol.—Pyrocatechol methyl cetyl ether,

$$C_6H_4(OCH_3)(OC_{16}H_{33}).$$

Chinaphenin. See quinaphenin.

Chinaphthol. See quinaphthol.

Chineonal. See quineonal.

Chininum lygosinatum. See quinine lygosinate.

Chinoform. See quinoform.

Chinosol. See quinosol.

Chloralamid.—Chloral formamide, $CCl_3.CH(OH).CO.NH_2$

Chloretone.—Trichloro tertiary butyl alcohol, $CCl_3.(CH_3)_2C.OH,\frac{1}{2}H_2O$.

Chlorin.—Dinitroresorcinol, $(NOH)O : C_6H_2 : O(NOH)$.

Chlorobrom.—A solution of potassium bromide 6, chloral formamide 6, and water 58 parts.

Chloryl anaesthetic.—Ethyl chloride.

Chromoform.—Combination of methylhexamethylenetetramine and dichromic acid, $(C_6H_{12}N_4CH_3)_2Cr_2O_7$.

Chrysoform.—Dibromodi-iodohexamethylenetetramine, $C_6H_8Br_2I_2N_4$.

Cibrola.—Preparation of milk and glycerophosphates.

Cicatricine.—A solution containing thiosinamine, 20, antipyrine 33. and eucaine lactate 0·65 part per 100.

Citarin.—Sodium anhydromethylenecitrate,

$$O<\begin{matrix}CH_2\\CO\end{matrix}>CO<\begin{matrix}CH_2.COONa\\CH_2.COONa\end{matrix}$$

Citrocoll.—Neutral aminophenacetin citrate.

Cocaethylin.—Ethyl ester of benzoylecgonine,

$$C_6H_5CO.C_8H_{13}NO.COOC_2H_5.$$

Codeonal.—Mixture of 1 part of medinal and 2 of codeine-veronal.

Colalin.—Cholalic acid. $C_{24}H_{40}O_5,H_2O$.

Coryfin.—Menthyl ethyl glycollate,

$$CH_2O(C_{10}H_{19}).COOC_2H_5.$$

Coxpyrin. See acetosal.

Cresegol.—Mercury-potassium salt of cresolsulphonic acid.

Cresosteril.—Acid ortho-oxalic ester of *m*-cresol,

$$CH_3.C_6H_4O.C(OH)_2.C(OH)_2.OC_6H_4(CH_3).$$

Cryogenin.—*m*-Benzaminosemicarbazide,

$$NH_2.CO.C_6H_4NH.NH.CO.NH_2.$$

Cupferron.—Ammonium compound of nitrosophenylhydroxylamine.

Cupratin.—Copper albuminate.

Cupri-aseptol.—Copper *m*-phenolsulphonate,

$$(HO.C_6H_4.SO_3)_2Cu.$$

Cupricin.—Cuprous cyanide.

Cuprocitrol.—Copper citrate, $2Cu_2C_6H_4O_7,5H_2O$.

Cuprol.—Compound of nucleinic acid and copper.

Cusylol.—Soluble copper citrate.

Cycloform.—Isobutyl ester of *p*-aminobenzoic acid, $C_6H_4(NH_2)COOC_4H_9$.

Cypridol.—Mercuric iodide (1%) in sterilised oil.

Cystamin. See hexamine.

Cystogen. See hexamine.

Cystopurin.—Addition product of hexamethylenetetramine and sodium acetate, $C_6H_{12}N_4.2C_2H_3O_2Na,6H_2O$.

Deba. See veronal.

Dentalone.—Solution of chloretone in essential oils.

Dermogen. See ektogen.

Desalgin.—"Colloidal chloroform": an albuminous substance combined with about 25% $CHCl_3$.

Dial-Ciba.—Diallylbarbituric acid,

$$(C_3H_5)_2C<\begin{matrix}CO.NH\\CO.NH\end{matrix}>CO.$$

Diaspirin.—Succinylsalicylic acid,

$$(CH_2.COO)_2(C_6H_4COOH)_2.$$

Digipotene.—Preparation containing the whole of the glucosides of digitalis leaves.

Dioform.—Acetylene dichloride, $CHCl : CHCl$.

Diogen.—Sodium salt of aminonaphtholdisulphonic acid, $NH_2.C_{10}H_4(OH)(SO_3Na)_2$.

Diogenal.—Dibromopropyldiethylbarbituric acid,

$$(C_2H_5)_2C<\begin{matrix}CO.N(C_3H_5Br_2)\\CO\text{———}NH\end{matrix}>CO$$

Dioxogen.—A 3% solution of hydrogen peroxide.

Diplosal.—Salicylosalicylic acid,

$$HO.C_6H_4.CO.O.C_6H_4.COOH.$$

Dipropæsin.—Urea derivative containing the residues of 2 mols. of propæsin, $CO(NH.C_6H_4.CO_2C_3H_7)_2$.

Disalol.—Phenyl salicylosalicylate,

$$HO.C_6H_4.CO.O.C_6H_4.COOC_6H_5.$$

Dispermin.—Piperazine.

$$NH<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}>NH.$$

Durine.—A formalin preparation.

Dymal.—Didymium salicylate.

Edinol.—*m*-Amino-*o*-hydroxybenzyl alcohol hydrochloride, $HO.C_6H_3(NH_2)CH_2OH,HCl$.

Ehrlich-Hata "606." See salvarsan.

Ektogen. Zinc peroxide.

Elarson.—Strontium salt of chloroarsenobehenolic acid (13% As.).

Elbon.—Cinnamoyl-*p*-hydroxyphenylurea.

Electrargol.—Electrolytic colloidal silver.

Embarin.—Sodium mercurisalicylsulphonate.

Empyroform.—Condensation product of tar and formaldehyde.

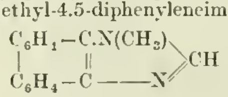
Enesol.—Mercury salicylarsenate (38% Hg).

Epinene.—3.4-Dihydroxyphenylethylmethylamine,

$$(HO)_2C_6H_3.CH_2.CH_2.NH.CH_3.$$

Epinephrine.—*o*-Dihydroxy-4-methylaminoethanolbenzene, $(HO)_2.C_6H_3.CH(OH).CH_2.NH.CH_3$.

Epiosine.—1-Methyl-4.5-diphenyleneimidazole,



Epirenan. See adrenaline.

Erepton.—Meat preparation in which proteins are completely resolved into amino-acids.

Ericin. See mesotan.

Ervasin.—Acetylcresotinic acid.

Escalin.—Aluminium powder mixed to a paste with glycerin.

Estoral.—Menthyl borate, $B(O.C_{10}H_{19})_3$.

Euboruyl.—α-Bromoisovaleric ester of borneol.

$$C_4H_8Br.COOC_{10}H_{17}.$$

Eucodeine.—Codeine methyl bromide, $C_{18}H_{21}NO_3.CH_3Br$.

Eucol.—Guaiacol acetate, $CH_3O.C_6H_4O.C_2H_3O$.

Eudrenine.—A solution containing 0·01 grm. of eucaine and 0·03 mgrm. of adrenaline per c.c.

Euguform.—Acetylated guaiaform (condensation product of guaiacol and formaldehyde).

Eulatin.—Mixture of *p*-bromobenzoic acid, *o*-aminobenzoic acid, and antipyrine.

Eumydrine.—Methylatropine nitrate,

$$C_{16}H_{20}NO_2(CH_3)_2NO_3.$$

Euphyllin.—Mixture of equal proportions of primary and secondary theophylline-ethylenediamine,

$$C_2H_4(NH_2)_2,C_7H_8N_4O_2+C_2H_4(NH_2)_2,2C_7H_8N_4O_2.$$

Eupnine.—Caffeine preparation containing iodine.

Euporphine.—Apomorphine methyl bromide,

$$C_{17}H_{17}NO_2.CH_3Br,H_2O.$$

Eupyrine.—*p*-Phenetidine-vanillin ethyl carbonate.

$$C_6H_4(OC_2H_5)N : CH.C_6H_3(OCH_3)O.CO_2C_2H_5.$$

Euresol.—Resorcinol monoacetate, $C_6H_4(OH)(O·C_2H_3O)$.

Euquinine.—Quinine ethyl carbonate,

$$C_2H_5O.CO.OC_{20}H_{23}N_2O.$$

Euscopol.—Inactive scopolamine hydrobromide,

$$C_{17}H_{21}NO_4,HBr.$$

Eustenin.—Addition product of theobromine-sodium and sodium iodide, $C_7H_7N_4O_2Na,NaI$.

Exodin.—Mixture of diacetylrufigallic acid tetramethyl ether 23, rufigallic hexamethyl ether 30, and acetylrufigallic pentamethyl ether 47%.

Fæxin. See ceredine.

Fermenlactyl.—Preparation of lactic acid bacilli.

Feronuclin.—Dry yeast extract.

Ferratogen. See ferrinol.

Ferrichthol.—Ichthyol preparation containing iron.

Ferrinol.—Iron nucleinate; contains 21% Fe_2O_3 and 2½% P.

Fibrolysin.—15% solution of a combination of thiosinamine (2 mols.) and sodium salicylate (1 mol.).

Fluoram.—Ammonium bifluoride.

Forgenin.—Tetramethyl-ammonium formate,

$$H.COON(CH_3)_4.$$

Formamint.—Preparation obtained from 1 mol. of lactose and at least 5 mols. of formaldehyde.

Forman.—Chloromethyl menthyl ether, $C_{10}H_{19}O.CH_2Cl$.

Formicin.—Formaldehyde-acetamide,

$$CH_3.CO.NH.CH_2OH \text{ or } CH_3.C(: NH).O.CH_2OH.$$

Formidin.—Methylenedisalicylic iodide, $C_{15}H_{16}O_6I_2$.

Formitrol.—Formaldehyde preparation.

Formolyptol. See formitrol.

Formurol.—Addition product of hexamethylenetetramine and sodium citrate, $C_6H_{12}N_4,C_6H_7O_7Na$.

Fredo.—Calcium hydrosulphite.

Furfurin.—A glyoxaline derivative, $C_3H_3N_2(C_4H_3O)_3$.

Gaduol.—Extract containing the alcohol-soluble constituents of cod-liver oil.

Gallogen.—Ellagic acid, $C_{14}H_6O_8$.

Gastrosan.—Bismuth bisalicylate.

Gaultheriasalol.—Methyl salicylosalicylate,

$$HO.C_6H_4.CO.OC_6H_4.COOCH_3.$$

Glidine.—A protein preparation from wheat.

Glonoin.—Nitroglycerin.

Glycarbin.—Glyceryl carbonate.

Glycerin-formal.—A condensation product of formaldehyde and glycerol,

$$\begin{matrix} & O.CH_2.O & \\ CH_2OH.CH & \text{——} & CH_2.\end{matrix}$$

Glycobrom.—Glyceryl ester of dibromohydrocinnamic acid, $C_3H_5[O.CO.(CHBr)_2C_6H_5]_3$.

Glycocyamine.—Guanidine acetic acid.

Glycosal.—Monosalicylic ester of glycerol,

$$C_3H_5(OH)_2.O.CO.C_6H_4(OH).$$

Gomaine.—Solution of iodoform and camphor in sesamé oil.

Griserin, Novum.—Iodohydroxyquinoline sulphonic acid, $C_9H_4I(OH)(SO_3H)N$, mixed with 20% $NaHCO_3$.

Guaiachinol.—Quinine dibromoguaiacolate,

$$C_6H_2Br_2(OCH_3)OH,C_{20}H_{24}N_2O_2.$$

Guaiamaltin.—Mixture of malt extract and potassium sulphoguaiacolate.

Guatannin.—Guaiacol tannocinnamate.

Gynoval.—Isobornyl isovalerate, $C_4H_9.COOC_{10}H_{17}$.

Hectine.—Sodium benzosulpho-*p*-aminophenylarsinate, $C_6H_5.SO_2.NH.C_6H_4.AsO(OH)(ONa)$.

Hediorite.—Lactone of α-glucoheptonic acid.

Hegonon.—Ammonio-silver nitrate-albumose (7% Ag).
Helcosol.—Basic bismuth pyrogallate, $HO.C_6H_3O_2BiOH$.
Helicon. See acetosal.
Helmitol.—Hexamethylenetetramine anhydromethylene-citrate, $C_6H_{12}N_4.C_7H_6O_7$.
Hemisine. See adrenaline.
Hermophenyl.—Mercury sodium phenoldisulphonate, $(SO_3Na)_2C_6H_2O(Hg)$.
Hetoform.—Basic bismuth cinnamate,

$$(C_6H_5.CH:CH.CO_2)_3Bi,Bi_2O_3.$$

Hetralin.—Addition product of resorcinol and hexamethylenetetramine, $C_6H_{12}N_4.C_6H_4(OH)_2$.
Hexal.—Hexamethylenetetramine salicylsulphonic acid, $C_6H_{12}N_4.(HO)C_6H_3(COOH)SO_3H$.
Hexamine.—Hexamethylenetetramine, $C_6H_{12}N_4$.
Hexanatrin.—Combination of hexamethylenetetramine and acid sodium phosphate.
Hexanitrin.—Mannitol hexanitrate,—

$$CH_2O(NO_2)(CHO.NO_2)_4.CH_2ONO_2.$$

Histamin.—β-Iminazolylethylamino.
Homorenon.—Ethylaminoacetopyrocatechol hydrochloride, $(HO)_2.C_6H_3.CO.CH_2.NH(C_2H_5).HCl$.
Hopogan. See magnesium perhydrol.
Hydramin.—A combination of *p*-phenylenediamine and quinol.
Hydrargol.—Mercury succinimide, $[C_2H_4(CO)_2N]_2Hg$.
Hydrargotin.—Mercury tannate (50% Hg).
Hydrarsan.—Solution of a mixture of arsenious, mercuric and potassium iodides and antipyrine.
Hydriodol. See cypridol.
Hydropyrin. See apyron.
Hydrosulphite N.F.—Condensation product of formaldehyde and sodium hydrosulphite; a mixture of formaldehyde sodium bisulphite, $NaHSO_3,CH_2O$, and formaldehyde-sodium sulphoxylate, $NaHSO_2,CH_2O$.
Hydrosulphite N.F. extra, or conc., or extra conc.—Formaldehyde-sodium-sulphoxylate.
Hyperol.—Compound of hydrogen peroxide and urea, with a trace of citric acid to render it stable.
Hypnogen. See veronal.
Hydraldite A.—See hydrosulphite N.F.
Hydraldite C.—See hydrosulphite N.F. extra.
Iachiol.—Silver fluoride.
Ichthargan.—Silver ichthyolsulphonate (30% Ag).
Ichthermol.—Mercury compound of ichthyol.
Ichthosulphol.—Ichthyol.
Ichthynal. See ichthosulphol.
Ichthyolidin.—Piperazine ichthyolate.
Ichthyol-salicyl.—Mixture of ichthyol and sodium salicylate.
Imogen.—Sodium diaminonaphtholsulphonate,

$$(NH_2)_2C_{10}H_4(OH)SO_3Na.$$

Indoform.—Salicylic methylene acetate; from formaldehyde and acetylsalicylic acid.
Insipin.—Diglycollic ester of quinine sulphate,

$$(CH_2COO.C_{20}H_{23}N_2O)_2O,H_2SO_4,3H_2O.$$

Iodanytol.—10% solution of iodine in anytin (a 33% solution of ichthyol).
Iodeigon.—Albumin preparation containing iodine.
Iodin.—Iodised arachis oil.
Iodinol.—Iodised sesamé oil.
Iodival.—Monoiodoisovalerylurea.

$$(CH_3)_2CH.CHI.CO.NH.CO.NH_2.$$

Iodocol.—Prepared from guaiacol and iodine in sodium oline.
Iodofan.—Monoiododihydroxybenzene-formaldehyde.
Iodoglidine.—Preparation of wheat gluten containing 10% I.
Iodoglobin.—Di-iodotyrosine,

$$HO.C_6H_2I_2.CH_2.CH(COOH)NH_2.$$

Iodogluten.—Preparation of vegetable albumin containing 8% I.
Iodolen.—Combination of iodol (tetra-iodopyrrole) and lbumin; contains 30% iodol.
Iodolin.—Quinoline chloromethyliodochloride,

$$C_9H_7N(CH_3Cl)CH.$$

Iodolinum. See iodolin.
Iodolysin.—Preparation similar to tiodine; contains 43% thiosinamine and 47% I.
Iodomenin.—Iodised casein containing bismuth (10% I).
Iodophenin.—Tri-iodophenacetin.
Iodoprotein.—Albumin preparation containing 10% I.
Iodozol.—Di-iodo-p-phenolsulphonic acid,

$$C_6H_2I_2(OH)SO_3H,3H_2O.$$

Iodylin.—Bismuth iodosalicylate.
Iodyloform.—Iodised gelatin (10% I).
Iohydrin.—Di-iodoisopropyl alcohol,

$$CH_2I.CH(OH).CH_2I.$$

Iothion. See iohydrin.
Isarol. See ichthosulphol.
Isoform.—*p*-Iodoxyanisol, $CH_3O.C_6H_4.IO_2$.
Isopral.—Trichloroisopropyl alcohol, $CCl_3.CH(OH).CH_3$.
Istizin.—1.8-Dihydroxyanthraquinone.
Jecovol.—Emulsion of cod-liver oil with glycerophosphates of sodium, calcium and iron.
Joha.—Solution of 40% of salvarsan in iodinol.
Kachin.—A pyrocatechol photographic developer.
Kakodyljacol. See cacodyliagol.
Kalmopyrin.—Calcium acetylsalicylate,

$$(C_2H_3O.OC_6H_4.COO)_2Ca$$

Kalzose.—Casein preparation containing calcium.
Kephaldol.—Preparation made from phenetidine and salicylic and citric acids.
Kinetine.—Combination of quinine and hectine.
Kineurine.—Quinine glycerophosphate,

$$C_3H_7O_3H_2PO_3(C_{20}H_{24}N_2O_2)_2,4H_2O.$$

Koronium bromide.—Strontium bromide, $SrBr_2.6H_2O$.
Krelos.—Mixture of tar distillates and rosin soap solution.
Kresegol. See cresegol.
Kresosteril. See cresosteril.
Kryogenin. See cryogenin.
Kynurin.—*p*-Hydroxyquinoline, $C_9H_6(OH)N$.
Lactagol.—Powdered extract of cotton-seed.
Lactanin.—Bismuth bilacto-monotannate.
Lacteol.—Preparation of lactic acid baccilli.
Lactigen. See lacteol.
Lactilloids. See lacteol.
Lactobaccilline. See lacteol.
Lactone. See lacteol.
Laxans. See purgen.
Laxatol. See purgen.
Laxen. See purgen.
Laxoin. See purgen.
Lecithol.—Lecithin from egg yolk.
Lecutyl.—Combination of lecithin and copper cinnamate (1·5% Cu).
Lenicet.—Basic aluminium acetate,

$$Al_2(OH)_2(C_2H_3O_2)_4,H_2O.$$

Lentin.—*m*-Phenylenediamine hydrochloride,

$$C_6H_4(NH_2)_2,2HCl.$$

Leptynol.—Colloidal palladous hydroxide suspended in sesamé oil.

Leucoline.—Quinoline, 
$$C_6H_4\left<\begin{matrix}CH:CH\\ N:\dot{C}H\end{matrix}\right.$$

Levurargyre.—Mercury compound of nucleoprotein.
Levuretin.—Dried yeast cells.
Levurinose. See levuretin.
Lipobromol.—Brominated poppyseed oil (33% Br).
Lipoiodin.—Di-iodobrassidic acid ethyl ester,

$$C_{19}H_{39}CI:CI.CO_2C_2H_5.$$

Lithium-diuretin.—Addition product of theobromine-lithium and lithium salicylate, $C_7H_7N_4O_2Li,HO.C_6H_4.CO_2Li$.
Lithyol. See ichthosulphol.
Lodal.—An oxidation product of laudanosine.
Lofotol.—Cod-liver oil charged with carbon dioxide.
Lucidol.—Benzoyl peroxide, $(C_6H_5.COO)_2O_2$.
Luesan.—Glidine preparation containing mercury.

Luminal.—Phenyl ethyl malonylurea,

$$\begin{matrix}C_2H_5\\C_6H_5\end{matrix}>C<\begin{matrix}CO.NH\\CO.NH\end{matrix}>CO$$

Lycin. See acidol.

Lygosin.—Di-hydroxydibenzalacetone,

$$(HO.C_6H_4.CH : CH)_2CO.$$

Lysochlor.—Chloro-*m*-cresol, $C_6H_3Cl(CH_3)OH$.

Lysoform.—A liquid formaldehyde potassium soap.

Magnesium-perhydrol.—Mixture containing magnesia and 15 or 25% MgO_2.

Malonal. See veronal.

Malourea. See veronal.

Maltyl.—Dry malt extract; contains about 90% of soluble carbohydrates.

Maretin.—*m*-Tolylsemicarbazide,

$$CH_3.C_6H_4.NH.NH.CO.NH_2.$$

Maricol.—Magnesium ricinoleate, $(HO.C_{17}H_{32}CO_2)_2Mg$.

Medinal.—Sodium compound of veronal.

Melrubin.—Sodium 1-phenyl-2.3-dimethylpyrazolone-4-aminomethane sulphonate, $C_{11}H_{11}N_2O.NH.CH_2.SO_3Na$.

Melubrin.—Mercury salicylsulphonate.

Menthophenol.—Mixture of phenol 1, menthol 3 parts.

Mercuriocoleolo.—Double oleate of cholesterol and mercury.

Mergal.—A combination of mercury cholate and albumin tannate.

Merjodin.—Mercury di-iodophenol-*p*-sulphonate,

$$(HO.C_6H_2I_2.SO_3)_2Hg.$$

Merlusan.—Mercury compound of tyrosine (53% Hg), $C_9H_9O_3NHg$.

Merochinol.—Mercury hydroxyquinolinesulphonate,

$$(HO.C_9H_5N.SO_3)_2Hg.$$

Mesotan.—Salicylic methoxymethyl ester,

$$HO.C_6H_4.COO.CH_2.OCH_3.$$

Methozin.—Antipyrine (phenyldimethylpyrazolone),

$$C_6H_5.N<\begin{matrix}CO—\!—CH\\N(CH_3).\ddot{C}.CH_3\end{matrix}$$

Methylrhodin.—Methyl acetylsalicylate,

$$C_2H_3O.O.C_6H_4.CO_2CH_3.$$

Metoquinone.—Addition product of metol (methyl-*p*-aminophenol) and quinol, $C_6H_4[HO(CH_3)NH.C_6H_4.OH]_2$.

Metramine.—See hexamine.

Migralgine.—Mixture of antipyrine 88, caffeine 9, and salicylic acid 3 parts, fused together.

Momordicine.—Elaterin, $C_{20}H_{28}O_5$.

Monotal.—Guaiacol methyl glycollate,

$$CH_2(OCH_3).COOC_6H_4.OCH_3.$$

Morphosan.—Morphine methyl bromide,

$$C_{17}H_{19}O_3N.CH_3Br,H_2O.$$

Mucogeène.—An anthraquinone derivative,

$$C_{18}H_{15}N_2O_2Cl.$$

Mydriasine.—Atropine methyl bromide,

$$C_{17}H_{23}NO_3,CH_3Br.$$

Naphtholsalol.—β-Naphthyl salicylate,

$$HO.C_6H_4.COO.C_{10}H_7.$$

Narcyl.—Ethylnarceine hydrochloride,

$$C_{23}H_{26}(C_2H_5)NO_8,HCl.$$

Nargol.—Silver nucleinate (10% Ag).

Nealpon. See pantopon.

Neoform.—Bismuth compound of tri-iodophenol,

$$C_6H_2I_3OBi(OH)_2,Bi_2O_3.$$

Neoleptol.—Triformyltrimethylenetriamine.

Neopine.—Hydroxycodeine, $C_{18}H_{20}NO_3(OH)$.

Neopyrin.—Valerylaminoantipyrine.

Neosalvarsan.—Sodium 3.3′-diamino-4.4′-dihydroxyarsenobenzene-formaldehyde sulphoxylate,

$$NH_2.C_6H_3(OH)As.As.C_6H_3(OH)NH(CH_2O)SONa.$$

Neosiode.—Iodocatechin, $(C_{15}H_{14}O_6,3H_2O)_3I$.

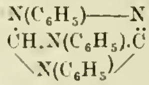
Nerolin.—β-Naphthyl methyl ether, $C_{10}H_7O.CH_3$.

Neuraltein.—Sodium *p*-ethoxyphenylaminomethane sulphonate, $C_2H_5O.C_6H_4.NH.CH_2.SO_3Na$.

Neuronal.—Diethylbromo-acetamide,

$$(C_2H_5)_2CBr.CO.NH_2.$$

Nitron.—1.4-Diphenyl-3.5-endanilodihydrotriazole,



Nizin.—Zinc sulphanilate, $(NH_2.C_6H_4.SO_3)_2Zn$.

Novargan.—Protein preparation containing 10% Ag.

Novaspirin.—Methylenecitrylsalicylic acid.

Novatophan.—Ethyl 6-methyl-2-phenylquinoline-4-carboxylate, $C_6H_5.C_9H_4N(CH_3)COOC_2H_5$.

Noviform.—Bismuth compound of tetrabromopyrocatechol.

Novocaine.—*p*-Aminobenzoyldiethylaminoethanol hydrochloride, $NH_2.C_6H_4CO.O.CH_2.CH_2.N(C_2H_5)_2,HCl$.

Novocol.—Sodium monoguaiacol phosphate.

Nucleogen.—Preparation containing iron nucleinate and arsenic.

Oleanodyne.—Preparation containing oleic acid, aconitine, atropine, morphine, and veratrine.

Oleoguaiacol.—Guaiacol oleate, $CH_3O.C_6H_4O.CO.C_{17}H_{33}$.

Omnopon. See pantopon.

Omorol. See novargan.

Optochin.—Ethylhydrocupreine.

Orexin.—Phenyldihydroquinazoline,

$$C_6H_4<\begin{matrix}N : CH\\CH_2\end{matrix}>N.C_6H_5.$$

Orsudan.—Sodium methyl acetyl-*p*-aminophenylarsinate $C_2H_3O.NH.C_6H_3(CH_3).AsO(OH)(ONa)$.

Ortizon.—See hyperol.

Ovoferrin.—Vitellin preparation containing iron.

Oxylith.—Sodium peroxide.

Oxyntin.—A combination of albumin and hydrochloric acid.

Palmiacol. See cetiacol.

Pantopon.—Mixture of the soluble hydrochlorides of opium alkaloids.

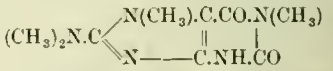
Parabismut.—Bismuth paranucleinate.

Paracodine.—Dihydrocodeine, $C_{17}H_{19}(OCH_3)(OH)NO$.

Paralysol.—Solid cresol preparation,

$$C_6H_4(CH_3)OK,3C_6H_4(CH_3)OH.$$

Paraxin.—Dimethylamino-1.7-dimethylxanthine,



Pegnine.—Preparation of lactose and rennet.

Pellidol.—Diacetylaminoazotoluene.

Pepsalia.—Preparation of pepsin and sodium chloride.

Perborax.—Sodium perborate, $NaBO_3,4H_2O$.

Perborol.—See perborax.

Perhydrit.—See hyperol.

Perhydrol.—Solution of hydrogen peroxide, 100 vol., o 30% by weight.

Permidan.—Dimethylaminopyrazolone, $C_5H_9N_3O$.

Phenalgin.—Phosphoammonioacetanilide.

Phenamine.—Amino-acet-*p*-phenetidine hydrochloride

$$C_2H_5O.C_6H_4.NH.CO.CH_2.NH_2,HCl.$$

Phenolax. See purgen.

Phenosal.—Monophenetidide of salicylacetic acid.

$$COOH.C_6H_4.O.CH_2.CO.NH.C_6H_4.OC_2H_5.$$

Phenoval.—Bromovalerylphenetidine,

$$C_4H_8Br.CO.NH.C_6H_4.OC_2H_5.$$

Phenyform.—Condensation product of phenol an formaldehyde.

Phenylon. See methozin.

Phobrol.—50% solution of chloro-*m*-cresol in potas castor oil soap.

Photoxylin. See celloidin.

Picrastol.—Dimethyloldiformylmethenyltetramethylen pentamine, $C_9H_{17}N_5O_4$.

Picratol.—Silver picrate.

Pinakol.—A pyrogallol photographic developer in which part of the alkali usually employed is replaced by sodium aminoacetate.

Piral.—Pyrogallol, $C_6H_3(OH)_3$.

Plecavol.—Consists chiefly of *p*-aminobenzoyleugenol, $NH_2.C_6H_4CO.O.C_6H_3(C_3H_5)OCH_3$, tricresol (a mixture of the three cresols) and formaldehyde.

Pleistopon.—Similar to pantopon, except that it contains no narcotine.

Pneumin.—Condensation product of creosote and formaldehyde.

Pneumosan.—Amyl thiotrimethylamine.

Propæsin.—Propyl ester of *p*-aminobenzoic acid,

$$NH_2.C_6H_4.COOC_3H_7.$$

Proponol.—Dipropylbarbituric acid,

$$(C_3H_7)_2C{<}\begin{array}{l}CO.NH\\CO.NH\end{array}{>}CO$$

Proposote.—Creosote phenylpropionate.

Protosal.—Salicyclic acid glycerol formal ester,

$$\begin{array}{r}O.CH_3.O\\HO.C_4H_4.CO.O.CH_2.\dot{C}H—\ \dot{C}H_2.\end{array}$$

Protylin.—Albumin preparation containing phosphorus.

Purgatin.—Anthrapurpurin diacetate,

$$C_{14}H_5O_2(OH)(O.C_2H_3O)_2$$

Purgatol. See purgatin.

Purgen.—Phenolphthalein, $C_6H_4{<}\begin{array}{l}C(C_6H_4.OH)_2\\OC\text{————}\end{array}{>}O.$

Pyoktanin.—Methyl Violet,

$$[C_6H_4.N(CH_3)_2]_2(C_6H_4.NH.CH_3)C.Cl.$$

Pyracetosalyl.—Addition product of antipyrine and acetylsalicylic acid, $C_{11}H_{12}N_2O+C_2H_3O.OC_6H_4.COOH_1$.

Pyrobromone.—Bromodimethylaminoantipyrine.

Pyronal.—Antipyrine salicylacetate,

$$C_{11}H_{12}N_2O,HO.C_6H_4CO.CH_2.COOH.$$

Pyrophan.—Combination of pyrogallol and dimethylamine.

Quietol.—Dimethylaminodimethylisovalerylpropyl ester hydrobromide.

Quinaphenin.—Phenetidine quinine carbonic ester,

$$CO(NH.C_6H_4.OC_2H_5)(C_{20}H_{23}N_2O_2).$$

Quinaphthol.—Quinine β-naphtholsulphonate,

$$C_{20}H_{24}N_2O_2,(HO.C_{10}H_6.SO_3H)_2.$$

Quineonal.—Compound of quinine and veronal

Quinine lygosinate.—Dihydroxydibenzalacetone-quinine,

$$CO(CH:CH.C_6H_4OH.C_{20}H_{24}N_2O_2)_2.$$

Quinoform.—Quinine formate, $C_{20}H_{24}N_2O_2,HCOOH$; also a condensation product of cinchotannic acid and formaldehyde.

Quinopyrin.—A combination of antipyrine, 2, and quinine hydrochloride, 3 parts.

Quinosol.—Mixture of hydroxyquinoline and potassium sulphates, $C_9H_6NOSO_3K,4H_2O$.

Quinotropin.—Hexamethylenetetramine quinate,

$$C_6H_{12}N_4,C_6H_7(OH)_4CO_2H.$$

Regulin.—Broken-up agar-agar with 25% of Cascara extract.

Resaldol.—Resorcylbenzoic acid ethyl ester,

$$(HO)_2C_6H_3.CO.C_6H_4.CO_2C_2H_5.$$

Rexotan.—Methylenetannin-urea,

$$C_{14}H_9O_9.CH_2.NH.CO.NH_2.$$

Rheumatin.—Saloquinine salicylate,

$$HO.C_6H_4.COO.C_{20}H_{23}N_2O,C_6H_4(OH)COOH.$$

Rhodaform.—Addition product of hexamethylenetetramine and methyl thiocyanate, $C_6H_{12}N_4,CH_3CNS$.

Riopan.—Soluble brown powder containing 50% of ipecacuanha alkaloids in the form of their hydrochlorides.

Rongalite C.—See hydrosulphite N.F. extra.

Sabromine.—Calcium dibromobehenate (29% Br),

$$(C_{22}H_{41}O_2Br_2)_2Ca$$

Sajodin.—Calcium monoiodobehenate, $(C_{22}H_{42}O_2I)_2Ca$.

Salacetin. See acetosal.

Saletin. See acetosal.

Salibromin.—Dibromosalicylic methyl ester,

$$C_6H_2Br_2(OH)COOCH_3.$$

Salicreol.—Creosote salicylate.

Salimenthol.—Menthyl salicylate, $HO.C_6H_4.COOC_{10}H_{19}$.

Salit.—Bornyl salicylate, $HO.C_6H_4.COO.C_{10}H_{17}$.

Salocreol. See salicreol.

Saloquinine.—Salicylquinine, $HO.C_6H_4.CO_2.C_{20}H_{23}N_2O$.

Salufer.—Sodium silicofluoride.

Salvarsan.—Dihydroxydiaminoarsenobenzene dihydrochloride,

$$HCl.NH_2(OH)C_6H_3.As.As.C_6H_3(OH)NH_2.HCl,2H_2O.$$

Salvarsan, New.—See neosalvarsan.

Santheose.—Theobromine, $C_5H_2(CH_3)_2N_4O_2$.

Santyl.—Santalyl salicylate, $HO.C_6H_4.COO.C_{15}H_{23}$.

Sauerin.—Preparation of lactic acid baccilli.

Savore.—Preparation of milk, cereal proteins and albumoses, and carbohydrates.

Scopomorphine.—Sterilised solution containing per c.c., 0·0006 grm. of euscopol and 0·015 grm. of morphine hydrochloride.

Sedeff.—Effervescent preparation containing opium, bismuth, and digestive ferments.

Sennatin.—Preparation containing the active principles of senna leaves.

Sennax.—Preparation containing the water-soluble glucosides of senna leaves.

Sidonal, New.—Mixture of quinic acid, $C_6H_7(OH)_4CO_2H$, and its anhydride.

Soamin.—Sodium arsanilate,

$$NH_2.C_6H_4.AsO(OH)(ONa),5H_2O.$$

Solurol.—Thyminic acid (nucleotinphosphoric acid).

$$C_{30}H_{46}N_4O_{15}(P_2O_5)_2.$$

Somnoform.—Mixture of ethyl chloride 60, methyl chloride 35, and ethyl bromide 5%.

Sophol.—Silver formonucleinate (20% Ag).

Spirarsyl.—Sodium salt of arsenophenylglycine,

$$(CO_2Na.CH_2.NH.C_6H_4)_2As_2.$$

Spirosal.—Monoglycol ester of salicylic acid,

$$HO.C_6H_4.COO.CH_2.CH_2OH.$$

Stearosan.—Compound of santalol and stearic acid.

Stovaine.—Hydrochloride of dimethylamino tertiary amyl benzoate, $C_6H_5COO.C(CH_3)(C_2H_5)CH_2N(CH_3)_2,HCl$.

Styptol.—Cotarnine phthalate,

$$(C_{12}H_{13}NO_3)_2,C_6H_4(COOH)_2.$$

Subcutin.—Anæsthesin phenolsulphonate,

$$C_6H_4(COOC_2H_5)NH_2,HO.C_6H_4.SO_3H.$$

Sublamine.—Mercuric ethylenediamine sulphate (43% Hg).

Sucramine.—Ammonium salt of saccharin.

Sulfoid.—Preparation of colloidal sulphur (80% S) with an albuminous substance as protective colloid.

Sulphoform.—Triphenylstibine sulphide, $(C_6H_5)_3SbS$.

Suprarenaline. See epinephrine.

Suprarenine. See adrenaline.

Synthalin.—Piperonylquinolinecarboxylic acid methyl ester, $CH_2O_2.C_6H_3.C_9H_5N.COOCH_3$.

Syrgol.—Colloidal silver.

Tachiol.—Silver fluoride.

Tanargan.—A combination of tannin and silver albuminate.

Tanninphenolmethane.—Condensation product of tannin formaldehyde and phenol.

Tanninthymolmethane.—Condensation product of tannin, formaldehyde, and thymol.

Tannismuth.—Bismuth bitannate.

Tannisol.—Methyleneditannin $(C_{14}H_9O_9)_2CH_2$.

Tannobromine.—A combination of dibromotannin and formaldehyde.

Tannocreosoform.—Condensation product of tannin, formaldehyde, and creosote.

Tannoguaiaform.—Condensation product of tannin, formaldehyde, and guaiacol.

Tannothymal. See tanninthymolmethane.

Tannyl.—Oxychlorocasein tannate.

Tenosin.—Solution containing, per c.c., 0·0005 grm. of β-iminazolylethylamine and 0·02 grm. of *p*-hydroxyphenylethylamine.

Testijodyl.—Combination of coagulated blood albumin and iodine.

Theobromose.—Lithium compound of theobromine, $C_7H_7N_4O_2Li$.

Theocin.—Sodium compound of theobromine,

$$C_7H_7N_4O_2Na.$$

Theolactin.—Addition product of theobromine sodium and sodium lactate.

Theosalin.—Addition product of theobromine-sodium and sodium sulphosalicylate, $C_7H_7N_4O_2Na,C_7H_5O_3.SO_3Na$.

Thephorin.—Addition product of theobromine-sodium and sodium formate, $C_7H_7N_4O_2Na,HCO_2Na,H_2O$.

Thermiol.—Sodium phenylpropiolate, $C_6H_5.C \vdots C.CO_2Na$.

Thialion.—Preparation containing sodium sulphate (26%), citrates of sodium (56), potassium (3) and lithium (3), sodium chloride (3) and water (9%).

Thigenol.—Sodium salt of ichthoform (condensation product of ichthyol and formaldehyde).

Thiophysem.—See tiodine.

Tholaform.—Mixture of equal parts of menthol and trioxymethylene.

Throphleol.—50% solution of erythrophleine hydrochloride (from casca bark) in eugenol.

Thymatol.—Thymol carbonate, $CO(O.C_{10}H_{13})_2$.

Thymegol.—Mercury potassium salt of thymol-*p*-sulphonate.

Thymolin.—Mixture of naphthalene 18, camphor 1, and thymol 1 part.

Thymoloform.—Condensation product of formaldehyde and thymol.

Thyresol.—Santalol methyl ether, $C_{15}H_{23}O.CH_3$.

Tiodine.—Thiosinamine ethyl iodide,

$$C_3H_5.NH.CS.NH_2,C_2H_5I.$$

Toxynon.—Sodium *m*-acetylaminomercuribenzoate, $HgOH.C_6H_3(NH.C_2H_3O)CO_2Na$.

Tricalcol.—Colloidal combination of tricalcium phosphate and albumin.

Tricarbin. See glycarbin.

Triferrin. See ferrinol.

Trigemin.—Compound of butyl chloral hydrate and pyramidone (dimethylaminoantipyrine).

Trilactine.—Preparation of lactic acid bacilli.

Trinitrin.—Nitroglycerin.

Trixidin.—An emulsion of antimony trioxide (30% Sb_2O_3).

Tryen.—See Griserin, Novum.

Trygase.—Dried yeast cells.

Trypan Red.—Prepared from tetrazotised benzidinesulphonic acid and 2 mols. of sodium naphthylaminedisulphonate,

$$\begin{array}{l}(SO_3H)C_6H_3.N_2.C_{10}H_4(SO_3Na)_2NH_2\\ \dot{C}_6H_4.N_2.C_{10}H_4(SO_3Na)_2NH_2.\end{array}$$

Tryparosan.—Chlorinated Parafuchsin.

Tylcalsin. See kalmopyrin.

Tyllithin. See apyron.

Tylmarin.—Acetyl-o-coumaric acid—

$$C_2H_3O.OC_6H_4.CH : CH.CO_2H.$$

Tylnatrin.—Sodium acetylsalicylate,

$$C_2H_3O.OC_6H_4.COONa.$$

Tyramine.—*p*-Hydroxyphenylethylamine hydrochloride,

$$HO.C_6H_4.C_2H_4.NH_2,HCl.$$

Ulmarene. See mesotan.

Unal.—Alkali salt of *p*-aminophenol hydrochloride; *rodinal* is the concentrated solution.

Uraminoantipyrin.—Antipyrylurea,

$$NH_2.CO.NH.C_{11}H_{11}N_2O.$$

Urapurgol. See helmitol.

Urea-bromine.—Combination of urea and calcium bromide (36% Br),$4CO(NH_2)_2,CaBr_2$.

Uritone.—See hexamine.

Urocitral.—Addition product of theobromine-sodium and sodium citrate.

Urodonal.—Granular preparation of hexamethylenetetramine, sidonal (piperazine quinate), and lysidine (methylglyoxalidine).

Urogenin.—Addition product of theobromine and lithium hippurate, $C_7H_8N_4O_2,C_6H_5.CO.NH.CH_2.CO_2Li$.

Urol.—Urea quinate.

Urosin.—Lithium quinate, $C_6H_7(OH)_4COOLi$.

Urotropine, New. See helmitol.

Valamin.—Isovaleric ester of tertiary amyl alcohol.

Valearin.—Valeryltrimethylammonium chloride.

Valisan.—Bornylbromoisovalerate,$C_4H_8BrCO.OC_{10}H_{17}$.

Valyl.—Valeric diethylamide, $C_4H_9.CO.N(C_2H_5)_2$.

Veronal.—Diethylbarbituric acid (diethylmalonylurea),

$$(C_2H_5)_2C\Big<\begin{matrix}CO.NH\\CO.NH\end{matrix}\Big>CO.$$

Veropyrin.—Mixture of dionine (ethylmorphine hydrochloride) 0·01, veronal-sodium 0·2, and kalmopyrin, 0·5 part.

Vesalvine. See hexamine.

Vesipyrine.—Phenyl acetylsalicylate,

$$CH_3.CO.OC_6H_4.COOC_6H_5.$$

Vimopyrin.—*p*-Phenetidine tartrate.

Vioform.—Hydroxyquinoline chloroiodide,

$$C_9H_6N(OH)ICl.$$

Vitafer.—Preparation of milk and glycerophosphates of calcium and sodium.

Xaxa. See acetosal.

Xaxaquin.—Quinine acetylsalicylate,

$$C_{20}H_{24}N_2O_2.CH_3CO.OC_6H_4.COOH.$$

Yara-yara.—See nerolin.

Yatren.—See Griserin, Novum.

Zymin.—Special dry powdered yeast.—A. S.

Report of Select Committee on Patent Medicines. Parliamentary Paper. Wyman and Sons, Fetter Lane, E.C. Price 3d. [T.R.]

The Select Committee appointed to consider and inquire into the question of the sale of patent and proprietary medicines and medical preparations and appliances, and advertisements relating thereto, and to report what amendments, if any, in the law are necessary or desirable," have issued their report. It deals with the law in foreign countries, in British Dominions and in the United Kingdom, legal and official anomalies, the inadequacy of existing law, statistics of the trade in proprietary remedies, analysis of secret remedies, fraudulent claims, etc.

Findings of the Committee.

After careful consideration of the evidence laid before them the Committee find :—

(1) That there is a large and increasing sale in this country of patent and proprietary remedies and appliances and of medicated wines.

(2) That these remedies are of widely differing characters, comprising (*a*) genuine scientific preparations; (*b*) unobjectionable remedies for simple ailments; and (*c*) many secret remedies making grossly exaggerated claims of efficacy; causing injury by leading sick persons to delay in securing medical treatment; containing in disguise large proportions of alcohol: sold for improper purposes; professing to cure diseases incurable by medication; or essentially and deliberately fraudulent.

(3) That this last-mentioned class (*c*) of remedies contains none which spring from therapeutical or medical knowledge, but that they are put upon the market by ignorant persons, and in many cases by cunning swindlers who exploit for their own profit the apparently invincible credulity of the public.

(4) That this constitutes a grave and widespread public evil.

(5) That in British Dominions and foreign countries severe legal restrictions exist, and that there is a tendency still further to strengthen the law against these articles.

(6) That no Department of State and no public officer is charged with the duty of controlling the sale and advertisement of proprietary remedies in this country; that the Home Office and the Local Government Board are virtually powerless in this respect; that the Privy Council Office, though supposed to be specially concerned with the sale of drugs, has no initiative in the matter, and, in fact, it fulfils no useful function in this connection.

(7) That the existing law is chaotic and has proved inoperative, and that successful prosecution for fraud in the advertisement and sale of secret remedies is fraught with the greatest difficulty, though the Public Prosecutor has perhaps not sufficiently tested the powers of the existing law in respect to such cases.

(8) That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of impropriety, is practically uncontrolled in this country.

(9) That this is an intolerable state of things, and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest.

(10) That grave injury is caused to the public by the existing large sale of medicated wines.

(11) And that while, for reasons already given, it is not desirable to require the exhibition of formula of every secret remedy, nevertheless it is improper that under the protection of the law enormous quantities of alleged remedies should be sold the composition of which is unknown to any person except the manufacturers of them; and that, therefore, the formulæ of all secret remedies should be required to be communicated to a competent officer appointed under the authority of a Minister of State, but that such formulæ should not be divulged to any other person except as hereinafter recommended.

Recommendations of the Committee.

The Committee, therefore, recommend:—

(1) That the administration of the law governing the advertisement and sale of patent, secret and proprietary medicines and appliances be co-ordinated and combined under the authority of one Department of State.

(2) That this administration be part of the functions of the Ministry of Public Health when such a Department is created, and that in the meanwhile it be undertaken by the Local Government Board.

(3) That a competent officer be appointed to this Department, with the duty of advising the Minister at the head of the Department concerned regarding the enforcement of the law in respect of these remedies.

(5) That there be established at the Department concerned a register of manufacturers, proprietors, and importers of patent, secret and proprietary remedies, and that every such person be required to apply for a certificate of registration and to furnish (*a*) the principal address of the responsible manufacturer or representative in this country, and (*b*) a list of the medicine or medicines proposed to be made or imported.

(6) That an exact and complete statement of the ingredients and the proportions of the same of every patent, secret, and proprietary remedy; of the contents other than wine, and the alcoholic strength of every medicated wine, and a full statement of the therapeutic claims made or to be made; and a specimen of every appliance for the cure of ailments other than recognised surgical appliances, be furnished to this Department, such information not to be disclosed except as hereinafter recommended, the Department to control such statement, at their discretion, by analyses made confidentially by the Government Chemist.

(7) That a Special Court or Commission be constituted with power to permit or to prohibit in the public interest, or on the ground of non-compliance with the law, the sale and advertisement of any patent, secret, or proprietary remedy or appliance, and that the Commission appointed for the purpose be a judicial authority such as a metropolitan police magistrate sitting with two assessors, one appointed by the Department and the other by some such body as the London Chamber of Commerce.

(8) That the President of the Local Government Board (or Minister of Health) have power to institute the necessary proceedings to enforce compliance with the law, the sale and advertisement of any patent, secret, or proprietary remedy, or appliance

(9) That a registration number be assigned to every remedy permitted to be sold, and that every bottle or package of it be required to bear the imprint "R.N. . . ." (with the number), and that no other words referring to the registration be permitted.

(10) That in the case of a remedy the sale of which is prohibited, the proprietor or manufacturer be entitled to appeal to the High Court against the prohibition.

(11) That the Department be empowered to require the name and proportion of any poisonous or potent drug forming an ingredient of any remedy to be exhibited upon the label.

(12) That inspectors be placed at the disposal of the Department to examine advertisements and observe the sale of proprietary remedies and appliances.

(13) That an annual fee be payable in respect of every registration number issued.

The Committee makes the following recommendations regarding the amendment of existing laws:—

(1) That the Stamp Acts be consolidated and amended to remove the numerous existing anomalies and unreasonable exceptions. In this connection, pure drugs vended entire under a fancy name should no longer be exempt from duty; the distinction between the name of an ailment, and the name of an organ the seat of that ailment, should be abandoned; and the exemption of medicines generating carbonic acid gas should be omitted. Further, any reference in advertising matter to the Government stamp should be prohibited, and no name of a proprietor or firm should be printed upon the stamp.

(2) That the Indecent Advertisements Act be amended on the lines of Lord Braye's Bill.

The Committee further recommend the following legislative enactments:—

(1) That every medicated wine, and every proprietary remedy containing more alcohol than that required for pharmacological purposes, be required to state upon the label the proportion of alcohol contained in it.

(2) That the advertisement and sale (except the sale by a doctor's order) of medicines purporting to cure the following diseases be prohibited:—

Cancer.	Diabetes.	Locomotor ataxy.
Consumption.	Paralysis.	Bright's disease.
Lupus.	Fits.	Rupture (without operation or appliance).
Deafness.	Epilepsy.	

(3) That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited.

(4) That all advertisements likely to suggest that a medicine is an abortifacient be prohibited.

(5) That it be a breach of the law to change the composition of a remedy without informing the Department of the proposed change.

(6) That fancy names for recognised drugs be subject to regulation.

(7) That the period of validity of a name used as a trade mark for a drug be limited, as in the case of patents and copyrights.

(8) That it be a breach of the law to give a false trade description of any remedy, and that the following be a definition of a false trade description:—"A statement, design, or device regarding any article or preparation, or the drugs or ingredients or substances contained therein, or the curative or therapeutic effect thereof, which is false or misleading in any particular." And that the onus of proof that he had reasonable ground for belief in the truth of any statement by him regarding a remedy be placed upon the manufacturer or proprietor of such remedy.

(9) That it be a breach of the law—

(*a*) To enclose with one remedy printed matter recommending another remedy.

(*b*) To invite sufferers from any ailment to correspond with the vendor of a remedy.

(*c*) To make use of the name of a fictitious person in connection with a remedy. (But it should be within the power of the Department to permit the exemption of an old-established remedy from this provision).

(*d*) To make use of fictitious testimonials.

(*e*) To publish a recommendation of a secret remedy by a medical practitioner unless his or her full name, qualifications, and address be given.

(*f*) To promise to return money paid if a cure is not effected.

In conclusion, the Committee believe that departmental and legislative action as outlined above will not inflict injustice upon any patent or proprietary medicine or appliance; that it will, alike by its operative and its deterrent effect, afford the public efficient and urgently needed protection against injury and fraud; and that no measures of a smaller scope will secure this result.

Patents.

[Medicinal] Table salt. F. Howe, Woodford Green, Essex. Eng. Pat. 22,322, Oct. 3, 1913.

Volatile oil of celery is incorporated by spraying with a mixture of sodium chloride and acetosalicylic acid. Proportions given are 10 grms. of the acid, 427·5 of sodium chloride, and 7·5 minims of a solution (1 in 10) of the oil in rectified spirit. The product is dried at a low temperature and sifted.—F. Sodn.

Formaldehyde; Process of making ——. H. von Hochstetter, Constance, Germany, Assignor to Perth Amboy Chemical Works, New York. U.S. Pat. 1,110,289, Sept. 8, 1914. Date of appl., April 28, 1914.

A mixture of methyl alcohol vapour and air is passed at a suitable temperature over a metal of the platinum group with which "is associated" another metal; rhodium and silver may be used as the two metals (see also U.S. Pat. 1,100,076; this J., 1914, 844).—T. F. B.

Organic bases; Manufacture of double compounds of —— [*with gold salts*]. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 276,134, Jan. 25, 1913.

Organic bases or their salts, other than cantharidylethylenediamine, are combined with auricyanic acid or an auricyanate, forming compounds which may be used in the treatment of tuberculosis (see also Ger. Pats. 269,661 and 272,291, and Eng. Pats. 1837 and 1869 of 1914; this J., 1914, 375, 568, 767, 806).—T. F. B.

Scopolamine solutions; Process for preparing ——. W. Straub. Ger. Pat. 276,554, Aug. 19, 1913. Addition to Ger. Pat. 266,415 (see this J., 1914, 42).

The polyhydric alcohol used in the process of the principal patent, is now replaced by a sugar. For example, a stable solution is obtained by dissolving 2 grms. of scopolamine hydrobromide in 7·5 litres of water, adding 600 grms. of dextrose, and pasteurising or sterilising.—T. F. B.

Coumarin; Process for preparing ——. Kinzlberger und Co. Ger. Pat. 276,667, Nov. 11, 1913.

Chlorohydrocinnamic acid is heated with an alkali hydroxide above 200° C., under pressure; the melilotic acid, which is produced in good yield, is converted by heat into hydrocoumarin, and this is dehydrogenated, *e.g.*, by heating with chlorine or sulphur, at a temperature near the boiling-point of coumarin.—T. F. B.

Sodium salt of acetylsalicylic acid and its homologues; Process for preparing the ——. J. A. Wülfing. Ger. Pat. 276,668, April 4, 1913. Addition to Ger. Pat. 270,326 (see this J., 1914, 139).

Acetylsalicylic acid or one of its homologues (in the benzene ring) is dried, finely powdered, and treated with an equivalent quantity of anhydrous sodium carbonate in presence of an alkyl ester of an aliphatic acid, *e.g.*, ethyl or methyl formate, or methyl or amyl acetate, but not ethyl acetate when making sodium acetylsalicylate.
—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Explosive; Antimony-sulphide-coated granulated ——. W. R. Hibbard, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,108,437, Aug. 25, 1914; date of appl., Sept. 20, 1913.

A black powder, the grains of which are coated with antimony pentasulphide.—E. W. L.

Explosives with liquid oxygen; Composition for forming ——. *Protective sheath or envelope for liquid-air or liquid-oxygen explosives.* G. Claude, Assignor to Soc. L'Air Liquide (Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude), Paris. U.S. Pats. 1,111,247 and 1,111,248, Sept. 22, 1914. Dates of appl., Jan. 25 and Feb. 4, 1913.

See Fr. Pats. 450,750 and 451,265 of 1912; this J., 1913, 627.—T. F. B.

XXIII.—ANALYTICAL PROCESSES.

Benzene; The freezing point of —— *as a fixed point in thermometry.* T. W. Richards and J. W. Shipley. J. Amer. Chem. Soc., 1914, **36**, 1825—1832.

The freezing point of pure benzene is recommended as a fixed temperature to be used, in connection with the ice point of water, for calibrating Beckmann thermometers. Samples of benzene from coal tar and prepared by synthesis, when purified by chemical treatment and fractional crystallisation, gave as a constant freezing point, 5·483° ± 0·002° C. on the international hydrogen scale.
—F. Sodn.

Electro-titrametric method and its application to general analytical chemistry; The ——. F. H. H. van Suchtelen and A. Itano. J. Amer. Chem. Soc., 1914, **36**, 1793—1803.

The precision and accuracy of the conductivity method of titration is illustrated by curves obtained in titrating strong and weak acids, besides Cl, Ag, SO_4, Ba, U, PO_4, NO_3, K, Ca, and Fe'', all of which were readily determined. The results were not affected by the presence of foreign substances, and it was found possible to determine more than one radical in the same solution by a suitable choice of reagents, Cl and SO_4, for example, being titrated with silver nitrate and barium nitrate respectively. The method has been successfully applied to the examination of biological liquids, such as urine.—F. Sodn.

Titanium; Volumetric determination of —— *by means of ferric chloride.* T. R. Ball and G. McP. Smith. J. Amer. Chem. Soc., 1914, **36**, 1838—1843.

The strongly acid solution, together with a large excess of zinc, is introduced into a separating funnel of 250 c.c. capacity, the funnel stem and an attached tube containing a filter of glass-wool and asbestos having previously been filled with freshly boiled water, air is displaced by carbon dioxide, the mouth of the funnel fitted with a Contat-Göckel valve (a modified form of which is figured), and reduction allowed to proceed for about 2 hours. The valve is then removed, the solution drawn through the filter into a suction flask (previously filled with carbon dioxide), the funnel washed with boiled water, without admitting air to the funnel tube, and the filtered liquid and washings (now containing titanium in the titanous condition) rapidly titrated with standard ferric chloride solution using potassium thiocyanate as indicator (see Hibbert, this J., 1909, 189). The metals Sn, Cr, V, W, and Mo interfere with the determination.—F. Sodn.

Carbon; Volumetric determination of —— *in aliphatic substances in the wet way.* E. C. Grey. Chem. Soc. Trans., 1914, **105**, 2204—2210.

Aliphatic substances can be oxidised to carbon dioxide, or to a mixture of carbon dioxide and acetic acid, by boiling with a mixture of potassium bichromate and phosphoric acid, and a volumetric determination of total carbon is based upon the estimation of these two products, the former gasometrically, and the latter by titration. 15 grms. of bichromate, 15 c.c. of phosphoric acid, and the substance (in solution) are placed in a 75 c.c. flask connected through a reflux condenser and a three-way tap to a gas burette charged with mercury on the one hand, and a small bulb-shaped gas reservoir on the other. Thirty minutes boiling is in most cases sufficient for oxidation, and the carbon dioxide is then displaced by means of water into the reservoir, and finally into the burette; where it is measured. The acetic acid produced, which is incidentally a rough measure of the number of methyl groups present, is distilled over with steam, and titrated in the usual way. A number of analyses are given of typical substances, including sugars, alcohols, and amino-acids, for the determination of which in biological work the method is particularly adapted, and the results are in good agreement with theory. The method is also suitable for the accurate determination of small concentrations of ethyl alcohol.—G. F. M.

Determination of sulphur in motor spirits. Bradbury and Owen. *See* IIA.

Trade Report.

Competition with Germany and Austria-Hungary. Third list of articles in respect of which applications have been received at the Board of Trade. October, 1914.

A THIRD list has now been issued by the Board of Trade, following those issued in August and September (see this J., 1914, 896 and 945); those interested should communicate with the Commercial Intelligence Branch, Board of Trade, 73, Basinghall Street, E.C.

A. *List of articles which inquirers desire to purchase:—*

Acetylcellulose; cellulose wadding. Chemicals: Acids, benzoic, carbolic, citric, cresylic, molybdic, salicylic, tannic, tungstic; butyl alcohol; arsenic, white and yellow; Neuburg chalk; white lead; carbon tetrachloride; ammonium chloride; calcium chloride; iron perchloride; cyanides and sulphocyanides; chemicals for dyeing, leather dressing, straw hat manufacture, tanning, and the textile trade; manganese; beta-naphthol; sodium nitrite; silver nitrate; oil, soluble sulphonated; potassium permanganate; sulphates and persulphates; magnesium sulphate; lead sulphide; lead hyposulphite; sodium bisulphite; tartar emetic. Clays: alum earth, kaolin, white earth for metal polishes. Drugs, essences and perfumes: eau-de-Cologne; menthol; perfumery for West African market; pomades; synthetic perfumes. Dyes: alizarin; auramine and similar yellows; eosine, for pigment colours, paper making, soaps, tanning trade, textile trade, tiles; indigo blue; phloxine; synthetic dyestuffs; vegetable dyestuffs. Esparto grass, Fire clay goods (general). Gelatin for straw hat manufacture. Glass and glassware: druggist sundries; for arc lamps; general for electrical lighting; hand-made flint glass; optical; philosophical instruments; sample tubes; surgical and chemical appliances; test tubes; vessels for electrical accumulators; water gauge glasses; windows; wire-embedded plate. Grinding materials; powder (substitute for kieselkreide). Lanoline. Lead and lead articles. Leather and leather goods: chamois; cloth; raw hide blanks. Machinery for applying coating composition to wood; for grinding, cutting, and bevelling glass; for making bronze powder, metal foils, starch, sugar, white porcelain enamel. Manures: fish meal, phosphorine; Matches: general (cheap). Metal foil: gold leaf, imitation, tin, metal, waste and scrap: brass, cast iron, copper, gunmetal, heavy iron and steel, iron and steel dust, iron and steel filings; mica. Oils and greases: animal oils; belt paste for machine belting; colza oil; for making "liquid paraffin"; palm kernel oil; tallow. Ores and minerals: basalt, broken; bauxite, crude; syenite stone. Paints, colours, and varnishes: colours, chemical; colours, mineral; colouring powders for high-class inks; for soaps and tiles; grease paints; ultramarine blue; varnish for electrical insulating; water colours (cheap); yellow ochre. Paper and paper articles: adhesive mounting tissue; carbon paper, ordinary; general; glazed transparent; glycerine parchment; insulating. Photographic appliances: baryta-coated paper for post cards; sensitised cardboard for post card photographs. Scientific instruments: balances; X-ray lamps. Skins: kid, for surgical applicanes; tan roan; white sheep. Size, "Sickel." Tungsten wire. Vinegar. Waterproofing materials, unimpregnated paper felt for waxes. Wire and wire working: lead tin and lead-antimony (alloy wire); brass; gauze, unspecified; iron, annealed and galvanised; lead; metallic filament; nickelled and bright soft iron. Wood wool. Zinc and zinc ware: dust; glazing plates for paper making; nickel-plated sheets; "preparation"; powder; rods; rolls; sheets; spelter; strips for boot eyelets; unspecified; vessels for douches; wire.

B. *List of articles which inquirers desire to sell:—*

Acetylene generators and lighting plant; alizarin oils; boilers, tanks, and metal receptacles; candles; capsules: metal; ceresine. Chemicals: acids; acetates; alcohols; arsenic and arsenites; carbonates; carbides; carbon; coal tar products; cyanides or prussiates; formaldehyde; formates; hydrates; iodides; nitrates; oxides; phosphates; radium and radio-active materials; sulphates; sulphides; sulphites; tartrates; thorium, (probably a salt); urea; zinc salts. Cochineal; collodion; fireclay goods; slag wool; stearine.

Applications in respect of German patents. Ch. of Comm. J., Oct., 1914.

THERE have been a certain number of applications made already under the Patents, Designs and Trade Marks Temporary Rules (Amendment) Act, 1914, for the avoidance or suspension of German patents in this country, and it is believed that at the present time nearly 30 other applications are waiting. They are made in the first instance to the Comptroller-General, who has been sitting with his predecessor for this purpose. These gentlemen do not give any decision, but make recommendations to the Board of Trade. However, they have laid down certain principles which are probably those which will be adopted. These are that it would not be fair to confiscate the property of German patentees; but that in all probability some kind of licence will be given to manufacture the articles in question, and that if a licence is continued after the war it will be subject to a royalty to be paid to the patentee, which may be settled in default of agreement by arbitration. They have also intimated that even if a licence is given only during the continuance of the war it will probably be fair that some royalty shall be payable to the State or to the patentee.

Imperial Institute. Technical Information Bureau. Times, Oct. 19, 1914.

This Bureau has been opened to deal with the steady increase of inquiries as to sources of supply of raw materials, methods of utilising new products from the Colonies and India, and new or little known processes and machinery for industrial purposes.

A statement is being prepared as to sources of potash which will include some hitherto untouched for industrial purposes. It is hoped to issue this by the end of the present year.

An equally important matter is that of finding markets for the immense quantities of raw materials from India and the Colonies formerly sent to Germany, such as palm kernels and copra. A statement giving full information regarding the German palm kernel industry has just appeared in the "Bulletin of the Imperial Institute." The Bureau will place manufacturers interested in these substances in communication with merchants who deal in them.

There is also a scarcity of thymol, because all the ajowan seeds from which it is extracted go to Germany from India. The preparation of thymol presents no difficulty.

Inquiries for the Technical Information Bureau should be addressed to the Director, Imperial Institute, S.W.

Development of U.S. natural resources. Oil, Paint, and Drug Rept., Oct. 5, 1914.

The Bureau of Foreign Trade Advisers in the State Department has been so much engaged with efforts to open up transportation facilities between the United States and Holland and other North European ports, that the possibility of obtaining mercury and other products through Italian ports, being possible reshipments from Austria and Servia, has not been seriously considered. Every effort is being made by the executive departments to help representatives of industries by ways and means to obtain materials in the United States. The facilities of the Geological Survey are being drawn upon for information in regard to increased mercury output in this country and also supplies of carbonate of magnesia, fluorspar, tin, and kindred commodities, important quantities of which are annually sent to this country from Europe. It is believed that American ships will be furnished to bring out of Germany through the ports of Holland supplies of fertiliser, chemicals products, and medicines, and efforts will be made to ascertain other openings for procuring necessary supplies in Europe.

Trading with the Enemy Act. First application under Sect. 3. Times, Oct. 21, 1914.

The first application to the Courts under Section 3 of the Trading with the Enemy Act, 1914, was made to Mr. Justice Warrington on October 20th. The Board of Trade, in accordance with the provisions of the Act, prayed that a controller might be appointed in the public interest to carry on the business of Meister, Lucius, and Brüning, Ltd., of Ellesmere, Lancs. The company was registered under the English Companies Acts, but all except 12 shares were held by German subjects resident in Germany. On the outbreak of war the secretary of the company received instructions from the directors to close the factory. The case raised some important points of procedure. His Lordship held (1) that applications under the Act might be made by motion; (2) that the Court should require evidence that the information on which the Board of Trade based its applications had reasonable foundation; (3) that the controller appointed should be ordered to give the usual security demanded from a receiver; (4) that the Court should reserve the power to require the controller to render and vouch his own accounts in addition to those of the company; and (5) that the controller should make periodical reports upon the company's business.

Prohibited exports and imports. Board of Trade Journal, Oct. 22, 1914.

The Privy Council approved on October 19th, a recommendation from the Board of Trade, to make certain alterations in the list of Prohibited Exports.

(1.) The prohibition of the export of molasses, invert sugar, and all sugar and extracts from sugar which cannot be completely tested by the polariscope, is withdrawn.

(2.) The prohibition of export of unrefined sugar and of refined sugar and candy is withdrawn as regards the Channel Islands, Malta, Gibraltar, Falkland Islands, St. Helena, East Africa Protectorate, and British West African Colonies and Protectorates.

(3.) The prohibition of the export of graphite (see this J., 1914, 988) is limited to "graphite suitable for the manufacture of crucibles."

In a Proclamation published in the "London Gazette" of October 26th, the Proclamation of September 30th is revoked as from October 26th, and the following provisions are substituted:—

The importation into the United Kingdom of all sugar is hereby prohibited provided that the foregoing prohibition shall not extend to sugar (not being raw or refined sugar made or produced by an enemy or in an enemy country, or refined sugar made or produced from raw sugar made or produced by an enemy or in an enemy country):—(*a*) Cleared from the port of shipment to this country on or before October 26th, 1914; (*b*) imported under contract made prior to August 4th, 1914.

Nothing in this Proclamation shall be taken to prohibit anything which shall be expressly permitted by our licence, or by the licence given on our behalf by a Secretary of State or the Board of Trade.

Book Received.

Chemical Technology and Analysis of Oils, Fats and Waxes. By Dr. J. Lewkowitsch, M.A., F.I.C. Fifth Edition, entirely rewritten and enlarged. In three volumes. Vol. II. Edited by G. H. Warburton. Macmillan and Co., Ltd., St. Martin's Street, London. 1914. Price 25s. net.

Volume, $8\frac{3}{4}$ by $6\frac{3}{8}$ ins., containing 936 pages of subject matter, with 19 illustrations, and also alphabetical indexes of botanical and zoological names. For Vol. I., see this J., 1913, 963. Vol. II. contains chapters on: XIII. Commercial preparation of the raw materials used in the oils, fats, and waxes industries. XIV. Technology of the natural oils, fats and waxes: methods of preparing, refining, and examining them, and detecting adulterations. A. Oils and fats (glycerides): vegetable drying oils, vegetable semi-drying oils, vegetable non-drying oils, marine animal oils, terrestrial animal oils, vegetable fats, animal fats. B. Waxes: Liquid waxes, solid vegetable waxes, solid animal waxes. Numerous hitherto unpublished observations are given under the headings of the individual oils and fats.

No. 21, Vol. XXXIII. NOVEMBER 16, 1914. No. 21, Vol. XXXIII.

Lecture.

THE PRESENT CONDITION OF THE CHEMISTRY OF ANTHRAQUINONE.

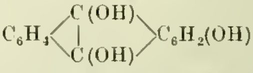
BY R. E. SCHMIDT.

Before the Société Chimique de France, December 6, 1913 (*Abstract*).

Bull. Soc. Chim., 1914, **15**, [12], 1—40.

During the twenty years following the synthesis of anthraquinone by Graebe and Liebermann, only a comparatively small number of anthracene dyestuffs was introduced; these were, in addition to Alizarin itself, Flavopurpurin, Anthrapurpurin, sulphonated Alizarin, Alizarin Blue, β-Nitro-alizarin, and Anthragallol, the last named, however, being obtained by condensing benzoic acid with gallic acid. To this number may be added synthetic Purpurin, which has not been applied in the dyeing industry. On the other hand, the last 25 years has witnessed a remarkable activity in researches on this class of dyestuff, which has resulted in the introduction of the Alizarin Cyanines, Anthracene Blues, Alizarin Green, and a large number of other dyestuffs, yellow, orange, red, violet, blue, and green, and all distinguished by a high degree of fastness. A systematic study of these dyestuffs has led to the formulation of certain rules as to the influence of the substituent groups on colour. Considering first the α-monosubstituted anthraquinones, it is seen that the nitro group and the halogens have practically no effect, though the α-bromo-derivative is slightly yellower than the α-chloro compound. α-Hydroxyanthraquinone is an intense yellow when in a finely divided condition, but the effect of the hydroxyl is neutralised by etherification or esterification, *e.g.*, the α-methoxy- and α-phenoxy-compounds are almost colourless. The SH group is similar to the hydroxyl group, but its effect is more pronounced. The amino group also increases the colour to brick-red, but in this case if the amino group is substituted by alkyl or aryl, the colour becomes bluish-red, whilst the introduction of acidic groups produces yellow compounds. The same remarks apply to the β-monosubstitution products, but here the colour changes are less marked. Among the disubstituted anthraquinones, the dihalogen and dinitro compounds have no tinctorial value. Of the dihydroxy derivatives, the ββ-compounds (2.3, 2.6, and 2.7) are the least coloured, then come the 1.5- and 1.6-compounds, and then the 1.2-, 1.3-, 1.6-, and 1.7-derivatives, whilst Quinizarin (1.4) is the most highly coloured. Again, the diaminoanthraquinones, 1.3, 1.5, 1.8, 2.6, and 2.7, are yellowish-red to brick-red, 1.2 is bluish red, and 1.4 is intense violet. The introduction of alkyl and aryl groups changes the shade towards blue and green, whilst acidic groups tend to produce lighter and yellower products. Many of the acidylaminoanthraquinones are valuable vat colours, unlike the aminoanthraquinones themselves; thus, 1.5-dibenzoyldiaminoanthraquinone (Algol Yellow R) dyes cotton very fast, deep yellow shades from the vat, and the 1.4-dibenzoyldiamino compound (Algol Red 5 G) dyes red shades. From the foregoing facts it is possible to determine the colour of the disubstituted anthraquinones in which the substituents are different: thus, α-aminoanthraquinone and its *p*-chloro, *p*-nitro, and *p*-methoxy derivatives are orange or brick red, whilst 1.4-aminohydroxyanthraquinone is bluish red, 1-amino-4-methylamino is bluish violet, 1-amino-4-tolylamino is blue, and 1.4-ditolyldiaminoanthraquinone is green. The same rules apply to the polysubstituted anthraquinones. Anthrachrysone (1.3.5.7-tetrahydroxyanthraquinone) is yellow, hydroxyflavopurpurin (1.2.4.6) orange, Alizarin Bordeaux (1.2.5.8) orange-red, and the 1.4.5.8-compound bluish-red. Of the isomeric dihydroxyditoluido compounds, 1.5-dihydroxy-4.8-ditoluidoanthraquinone is blue, the 1.2.5.8-compound (Alizarin Viridine) is green, and 1.4.5.8 is yellowish green. Two of the diaminodihydroxyanthraquinones, namely NH : NH : OH : OH = 1.5.4.8 and 1.8.4.5, are blue compounds, which, when sulphonated, are known as Alizarin Saphirol, and dye cotton very pure blue shades.

Introduction of substituent groups into anthraquinone and its derivatives. The nitro group is introduced by the usual methods. When anthraquinone is treated with very strong nitric acid, or with a mixture of nitric and sulphuric acids, α-nitroanthraquinone is first produced, and by more energetic treatment, the 1.5- and 1.8-dinitro derivatives in about equal amounts, accompanied by small quantities of the β- and αβ-compounds, such as 1.6, 1.7, 2.6, and 2.7. The nitration of anthraquinone derivatives generally produces α-nitro compounds; for example, anthraquinone-1- and 2-sulphonic acids are both converted into the 5- and 8-nitro derivatives. The secondary reactions liable to occur in the nitration of hydroxy or amino derivatives, can be prevented in the usual way, *e.g.*, by etherification or acidylation, respectively. The sulphonation of anthraquinone with acid alone necessitates the use of fuming acid at temperatures about 100° C.; this gives the β-monosulphonic acid and 2.6- and 2.7-disulphonic acids. The α-sulphonic acids 1, 1.5, and 1.8, are readily obtained by sulphonation in presence of small quantities of mercury. The introduction of chlorine or bromine into amino- or hydroxy-anthraquinones is effected by the usual methods, but anthraquinone itself resists these processes. Until recently, the only known methods of producing halogen-anthraquinones were to heat anthraquinone with bromine in sealed tubes, or to oxidise the polyhalogen-anthracenes. The present method consists in replacing the sulphonic group of anthraquinonesulphonic acids or their nitro-derivatives, by treatment in dilute aqueous solution with nascent bromine or chlorine, *e.g.*, with a mixture of sodium chlorate and hydrochloric acid: by this method it is possible to produce any desired halogen- or halogen-nitro-anthraquinone, in almost theoretical yield. It is also possible to introduce chlorine into anthraquinone and certain of its sulphonic acids by passing chlorine through their solutions in fuming sulphuric acid at a high temperature: thus anthraquinone may be converted into the 1.4.5.8-tetrachloro-compound, whilst anthraquinone-β-sulphonic acid gives the 1.4-dichloro-7-sulphonic acid. Several methods are known for introducing the hydroxyl group into the anthraquinone nucleus. The first consists in heating anthraquinone-β-sulphonic acids with caustic soda in presence of an oxidising agent, and is used for the preparation of Alizarin and Flavopurpurin. The sulphonic acids can be converted into the hydroxy compounds directly, without oxidation, by heating under pressure with alkaline earths; this method serves for the production of 1-mono and 1.5- and 1.8-dihydroxyanthraquinones. In the course of a study of the sulphonation of Alizarin under various conditions, the author found that a large excess of fuming acid (70—80% free SO_3) at 20°—40° C. did not sulphonate the Alizarin, but produced a high yield of 1.2.5.8-tetrahydroxyanthraquinone (Alizarin Bordeaux), in the form of its sulphuric ester; a more prolonged reaction resulted in the formation of the 1.2.4.5.6.8-hexahydroxy compound. This reaction is general for hydroxyanthraquinones containing at least one α-hydroxy group, but it has not yet been possible to forecast the exact progress of the reaction. Quinizarin, like Alizarin, is converted into the 1.2.5.8-compound; 1-hydroxyanthraquinone gives at first the 1.5-dihydroxy derivative, and later the hexahydroxy compound, whilst Chrysazine is converted rapidly and Anthrachrysone almost instantaneously into the same hexahydroxy compound. The presence of boric acid in this process retards the reaction considerably, probably owing to the formation of boric esters; this affords a method of controlling the reaction to produce intermediate hydroxy compounds, such as the 1.2.5-trihydroxy derivative from Alizarin and the 1.4.8-compound from Chrysazine. The boric esters are also of value in that they are very resistant to decomposition by sulphuric acid at high temperatures. By the use of pure sulphuric anhydride it is possible to introduce hydroxyl groups into anthraquinone itself, producing the 1.2.4.5.6.8-hexahydroxy derivative, though the yield is unsatisfactory. A number of hydroxyanthraquinones can be hydroxylated by means of ordinary sulphuric acid (66° B.) at a high temperature, *e.g.*, 160°—200° C. : by this method, Alizarin Bordeaux is converted into the 1.2.4.5.6.8-hexahydroxy-compound, together with small quantities of the 1.2.4.5.7.8-compound. Whilst studying this reaction, it was found that selenium and mercury are very active oxidation catalysts. Interesting results are obtained in presence of substances which are not catalysts, but actual oxidising agents, such as arsenic acid and nitrous acid. Anthragallol is converted into 1.2.3.4-tetrahydroxyanthraquinone and anthraquinone into Quinizarin by heating with sulphuric acid, boric acid, and sodium nitrite ; when pure sulphuric acid is used, no reaction takes place, but an energetic reaction is induced by traces of mercury. During this process an intermediate compound is formed, 1.4-diazohydroxyanthraquinone, which is stable towards boiling sulphuric acid of 60° B., but reacts with alcohol forming α-hydroxyanthraquinone. Lalande's method (treatment with manganese dioxide and sulphuric acid) is also an important hydroxylation process ; Alizarin is converted into Purpurin, and Alizarin Bordeaux into 1.2.4.5.8-penta- and two hexahydroxyanthraquinones, known as Alizarin Cyanine R, R extra, WRR, and Anthracene Blue WR. This method can be used to introduce further hydroxyl groups into any anthraquinone derivative which contains at least one hydroxyl in each benzene nucleus ; thus, β-nitroanthrapurpurin furnishes 3-nitro-1.2.4.5.7.8-hexahydroxyanthraquinone, Alizarin Cyanine Black G. Quite recently (see this J., 1913, 593 ; 1914, 545) this method has been used to prepare 1.2.4-purpurin-3-carboxylic acid, which gives a valuable alumina lake. The polyhydroxyanthraquinones are not formed immediately during this oxidation process ; true quinonoid compounds, called "anthradiquinones," are formed at first, which resemble benzoquinone, and these are converted into the corresponding hydroxy compounds by means of weak reducing agents. Among the other methods for introducing the hydroxyl group may be mentioned the replacement of bromine or nitro groups by heating with sulphuric and boric acids. The aminoanthraquinones are obtained by reducing the corresponding nitro compounds. When alkaline reducing agents are used, hydroxylamino compounds are obtained under certain conditions ; the 1.5-dihydroxylamino compound cannot be converted into diaminoanthraquinone by reduction, but on treatment with sulphuric acid it undergoes intramolecular transformation into the 1.5-diamino-4.8-dihydroxy compound. One of the most important methods of preparing aminoanthraquinones is by treating negatively-substituted anthraquinones with ammonia ; the hydroxyl group is readily replaced in this manner, *e.g.*, when Purpurin is evaporated with aqueous ammonia, 1-amino-2.4-dihydroxyanthraquinone is produced. By careful treatment of 1.5-dinitroanthraquinone with sulphur sesquioxide (sulphur dissolved in fuming sulphuric acid) it is possible to obtain the same diaminodihydroxy compound as described above, produced by intramolecular transformation of the dihydroxylamino compound ; it is therefore concluded that these hydroxylamino compounds are also intermediate products of the sulphur sesquioxide treatment, and the author has actually isolated the dihydroxylamino derivative corresponding to dinitrochrysazinedisulphonic acid. Treatment of the nitroanthraquinones with 40% fuming sulphuric acid alone produces finally hexahydroxy compounds and their sulphonic acids, whilst if 10—15% fuming acid is used, soluble colouring matters are obtained directly, which appear to consist chiefly of monosulphonic acids of diaminodihydroxyanthraquinones. The introduction of substituted amino groups into the anthraquinone nucleus is effected by treating negatively-substituted anthraquinones with methylamine, piperidine, etc. The preparation of the arylaminoanthraquinones from the hydroxy compounds is greatly facilitated by condensing agents such as boric acid. The condensation product of Purpurin with aniline is known as Alizarin Blue Black B, and the product from Quinizarin and two mols. of *p*-toluidine, in the form of its sulphonic acid, dyes wool fast green shades ; in the latter case, however, the yield is only 30—35%, owing to secondary reactions, including oxidation. A good yield of the dyestuff can be obtained by condensing *p*-toluidine with the reduction product of Quinizarin,



$$C_6H_4\left<\begin{matrix}C(OH)\\ |\\ C(OH)\end{matrix}\right>C_6H_2(OH)_2$$

and oxidising the product. Among the other dyestuffs of this series may be mentioned Alizarin Viridine, 1.4-di-*p*-tolylamino-7.8-dihydroxyanthraquinone, and Brilliant Alizarin Viridin, the corresponding 8-monohydroxy compound ; these form fast chrome lakes and are therefore of interest in calico printing. The formation of acridine compounds, which occurs when halogen-anthraquinones are heated with aromatic amines, is avoided by adding small quantities of sodium acetate or potassium carbonate to combine with the acid liberated. Alizarin Sky Blue is the sulphonic acid of 1-amino-2-bromo-4-*p*-tolylaminoanthraquinone, obtained by heating the corresponding dibromo compound with *p*-toluidine ; when this reaction is carried out in presence of copper, an almost insoluble compound is formed, which proved to be a derivative of Indanthrene, whilst Indanthrene itself can be obtained by heating 1-amino-2-bromoanthraquinone in nitrobenzene or naphthalene, in presence of sodium acetate and traces of copper. The catalytic effect of copper can be utilised generally in the condensation of halogen-anthraquinones with aminoanthraquinones, to produce compounds of the general formulæ, $C_{14}H_7O_2.NH.C_{14}H_7O_2$, and $C_{14}H_7O_2.NH.C_{14}H_6O_2.NH.C_{14}H_7O_2$. A number of these compounds are on the market as vat dyestuffs, such as Algol Orange, Algol Bordeaux, Indanthrene Red, etc.

In conclusion, attention is drawn to two important auxiliaries in the study of the anthraquinone compounds. The first is the spectroscope. Many anthraquinone derivatives present characteristic absorption spectra, which may be utilised for the detection of these compounds and also for controlling and following the progress of certain manufacturing processes, such as the oxidation of Alizarin Bordeaux to pentahydroxy- and hexahydroxyanthraquinone, each step of which is clearly marked by the spectrum. The second auxiliary is boric acid, which, in addition to its uses in manufacturing processes, is also o great value as an analytical reagent ; the boric esters o hydroxyanthraquinones are frequently characteristic, and many substances which exhibit no definite spectrum in sulphuric acid solution, give excellent results when bori acid is added. For example, on addition of boric acid the red-violet solution of Alizarin Blue becomes olive, the violet of Alizarin Bordeaux becomes blue, and the yellow solution of 1.5-diamino-4-hydroxyanthraquinone become red.—T. F. B.

Erratum and Addenda.

This Journal, 1914, page 775, col. 2, l. 29 from bottom *for* "W. Watson Gody" *read* "G. Watson Gray;" an references are as follow :—this J., 1901, pages 538 an 1027 ; also 1904, page 324.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

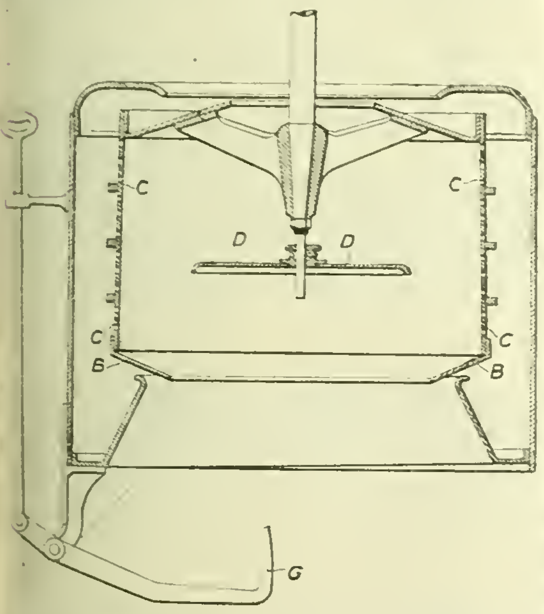
Patents.

Hydro-extractors and like centrifugal machines. T. K. Irwin, London. Eng. Pat. 13,508, June 11, 1913.

The liquid expelled from the cage of the machine impinges directly on the vanes of a turbine or rotor surrounding the cage, the power generated being utilised either directly or by means of gearing to drive a second centrifugal machine.—W. H. C.

Centrifugal machines. A. R. Robertson, Glasgow. Eng. Pat. 26,303, Nov. 17, 1913.

The fixed portion, B, of the bottom of the machine has an angle greater than the angle of repose of the dried material, so that when the movable bottom, D, is raised, he dried material falls out by its own weight. The asket, C, has the shape of an inverted frustum of a cone, o that when discharge takes place, the material comes way easily from the sides. An externally operated craper, G, may be used to assist in the discharge.—W.H.C.



ashing clinker, gravel or other granular material; Apparatus for ——. C. W. Marks, Wokingham, Berks. Eng. Pat. 21,135, Sept. 18, 1913.

he material receives a preliminary soaking in a rotary, nclined conical barrel provided with lifting and conveying lades and a perforated water-supply pipe, and is then elivered into a co-axial rotary screen or trommel. —W. H. C.

alp-washing machine. J. Schneible, Chicago, Ill. U.S. Pat. 1,111,408, Sept. 22, 1914; date of appl., June 5, 1913.

TNK having a conical bottom with a central discharge provided with a perforated inner bottom plate and a rotatable frame carrying agitator blades and a base-plate, the latter being parallel to the perforated bottom and serving to prevent the agitator from forcing the pulp through the perforations.—W. H. C.

Recuperator furnace. W. A. Stubblebine, Allentown, Pa. U.S. Pat. 1,111,414, Sept. 22, 1914; date of appl., Oct. 31, 1913.

A chequer-work air preheater is arranged in the hollow front wall of the fire-place of a reverberatory furnace and the heated air is delivered to various parts of the working hearth, beyond the bridge, through ducts formed in the side walls.—W. H. C.

Kiln. E. P. Stevens, Chicago, Ill. U.S. Pat. 1,111,871, Sept. 29, 1914; date of appl., Nov. 21, 1912.

The kiln has two heating chambers, arranged back to back and separated by a wall enclosing a series of vertical flues. Upon the inside of the front wall of each chamber is a fire-box from which heating flues extend upwards to the roof, across the latter, down the dividing wall, across the floor to the front wall, and thence to the vertical flues in the dividing wall.—W. E. F. P.

Device for measuring temperature. Eng. Pat. 5460. *See* XXIII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Sulphur compounds of coal; Oxidation of —— and of nitrogen, in the bomb calorimeter, and the correction to be applied in determining the heating value of coal. S. H. Regester. J. Ind. Eng. Chem., 1914, **6**, 812—822.

The results of the experiments indicate that the relative amounts of sulphur trioxide and dioxide in the bomb gases after combustion depend chiefly upon the amount of nitrogen oxides formed in the bomb, which promote the formation of the trioxide just as in the manufacture of sulphuric acid by the chamber process; the ash of the fuel does not appear to exert any appreciable catalytic action. The formation of nitrogen oxides takes place much more readily from the nitrogen of coal than from the nitrogen present in the bomb gases, and increases with increasing pressure and with the heat of combustion of the fuel. The usual correction applied to the heating value of a fuel, according to the sulphur content, based on the assumption that the sulphur is converted completely into sulphur trioxide in the calorimeter, is satisfactory in the case of coal with less than 2% S, burnt in a bomb calorimeter from which the initial charge of air is not removed by rinsing out with oxygen; in the case of coals high in sulphur, a material amount of sulphur may be left as sulphide in the ash and as sulphur dioxide in the gas. If the air in the bomb be blown out with oxygen of high purity so that the concentration of nitrogen in the bomb is only a fraction of 1%, then with a fuel free from nitrogen, only a part of the sulphur will be converted into sulphur trioxide. With a non-nitrogenous fuel containing less than 0·08 grm. of sulphur in the sample burned, approximately quantitative formation of sulphur trioxide is obtained at 20 atmospheres pressure if the nitrogen concentration of the bomb gases be 6%. The heat of combustion (to SO_3) of the sulphur of pyrites was found to be about 4975 calories per grm.—A. S.

Coking process; Theory of the ——. E. Donath. Stahl u. Eisen, 1914, **34**, 60—61.

A SAMPLE of coal from Rossitz, near Brünn, containing ash 4·64, H_2O 9·66, N 1·32, H 4·86, C 82·88, total S 3·35, S in ash 0·32, combustible S 3·03%, when heated in an experimental coke-oven gave a molten product sufficiently fluid to flow from a small opening at the base of the oven. This product quickly solidified to a shining black mass, containing ash 10·47, H_2O 0·50, N 0·14, H 2·99, C 76·86, total S 3·63, S in ash 2·18, combustible S 1·45, O 7·59%. The whole of the organic constituents were volatilised when the product was heated in a covered crucible, leaving only the ash. This behaviour resembles that of tallow, wax and paraffin and some resins, and the author concludes that during the coking of a coal of this type, a mixture of compounds consisting of the degradation products of the resinous and fatty constituents of the original coal-forming materials and also the pitch-like polymerised products of distillation under pressure, is completely melted and decomposes on further heating without leaving any carbon residue. The decomposition products react chemically with the degradation products of the cellulose and protein constituents of the coal-forming material, cementing them into a carbon-like compound or mixture of compounds. At higher temperatures, the protein degradation products in the coal soften and during the complete gasification of the coal, stable compounds are formed containing sulphur and nitrogen, and these compounds are present in the coke.—A. T. L.

Coke; Blast-furnace ——. O. Simmersbach. Stahl u. Eisen, 1914, **34**, 108—110.

THE effect of modifying the conditions of coking, such as the size of the retort, and the temperature, is discussed. The formation of cracks may be diminished by the admixture of lean coal or powdered coke. Coking at too low a temperature may leave cores of uncoked coal containing up to 20% of volatile matter, and yielding for example, on distillation, tar 1·85%, CO_2 0·8, H_2S 0·1, H_2O 2·59, NH_3 0·31, C_6H_6 0·25, gases (CH_4, H_2, CO) 6·35; total volatile matter 12·25%. Incomplete coking is shown by the presence of more than 0·6% H_2. Experiments supporting Bone's view (this J., 1908, 886) showed that compact, hard carbon is obtained by passing methane through a hot tube, while ethylene yields a sooty mass. These varieties of carbon are found in coke. In quenching, the appearance of the coke depends upon the use of clean water. In addition to its appearance, the behaviour of a coke when dropped upon a hard surface gives an indication of its quality.—O. E. M.

Blast-furnace coke. H. Koppers. Stahl u. Eisen, 1914, **34**, 585—587.

RAPIDITY and uniformity of combustion of blast-furnace coke in the blast-furnace, have an important effect on the results obtained, and are promoted by restricting the water-content of the coal, which should be of uniform composition, to 9%, by coking rapidly in uniformly heated ovens, by not allowing the charge to stand in the oven when coking is complete, and by breaking and screening the coke into pieces between 12 and 90 mm. in diameter. Ovens are best built of lime-bound silica brick.—O. E. M.

Tar-formation temperatures of American coals. J. Gas Lighting, 1914, **128**, 134—135.

SAMPLES of coal were heated in a small resistance furnace, under conditions which resembled those of large scale practice but permitted of accurate measurement. With any grade of bituminous coal or lignite, tar began to distil at about 300° C., the maximum evolution was between 375° and 475° C., and the tar was all liberated at 550° C. or in a few cases 600° C. The temperatures did not depend upon the geological age of the coal, the amount of volatile matter, or the C : H ratio, and there was no relation between the amounts of volatile matter and of tar. The C : H ratio is a guide to the amount of tar, the greatest amount of thick tar being obtained from coals having this ratio from 13·5 to 18.—A. T. L.

Oil-tar separation, recovery, and disposal. R. E. Wyant. J. Gas Lighting, 1914, **128**, 131—132. (See also Beardsley, this J., 1912, 422.)

TAR partly separates in the form of an emulsion, and when the whole is mixed, the water-content is not excessive. When tar is accumulated in a tank, pumped off from the bottom, there was a further separation of tar and water. The proportion of water at different depths was:—at 18 in. from bottom, 2—3%; at 2 ft., 46%; at 4 ft. 6 in., 80%, and at 12 ft. 90%. The tar can be recovered from the emulsion by using the emulsion in place of water in the scrubbers. For use on roads, the tar is distilled preferably by heating it to 212° F. (100° C.) and blowing live steam through until the sp. gr. reaches 1·1 at 60° F. (15·5° C.), and the flash-point 145° F. (63° C.) if the tar is used for dust-laying. For road-surfacing the distillation is carried further. The tar is superior to petroleum oil for use on roads.—A. T. L.

[Coal gas] purification. Experiments at Montreal. H Mann. J. Gas Lighting, 1914, **128**, 84.

PURIFIERS filled with a single layer of oxide, 48 in. deep, were worked in sets of four, the gas passing downwards through the oxide, and each set of four purifiers passing 1¼ million cb. ft. of gas per day, containing 450 grain H_2S per 100 cb. ft. Air was admitted at the exhauste outlet in order to revivify the oxide in the foul box whic was placed last in the series. The oxide was not capabl of being revivified after the purifier had been operate continuously for two or three weeks, but by changing th connections so as to place the foul box last every 3 days the plant was worked for a year without renewing th oxide. In changing the order, *e.g.* from 1—2—3—4 t 2—3—4—1, the purifiers were worked for an hour in th order 4—1—2—3, so as to prevent foul gas in No. passing direct to the holder. The oxide became ver hard and the back-pressure increased, so that it wa decided to refill every 6 months. The oxygen admitte for revivification was not absorbed in the first and secon boxes where the gas still contained hydrogen sulphide The rearrangement of the purifiers with clean-box firs and foul-box last doubled their working capacity.—A. T. I

De Beque petroleum field in Colorado. G. R. De Beque Eng. and Min. J., 1914, **98**, 652—653.

A GENERAL resumé is given of the geology of the distric and the history of the oil development. The importan oil strata occur in the Mesaverde (Cretaceous) formatio A well, 2010 ft. deep, yields 100 barrels per day (b pumping) and is capable of a larger output. The oil golden brown in colour, extremely viscous, and solidifie quickly on exposure to air; it has a "32% paraffin base. —W. E. F. P.

Petroleum in Assam. E. H. Pascoe. Mem. Geol. Sur India, 1912, **40**, Pt. 2. Bull. Imp. Inst., 1914, 1 474—475.

THE petroleum deposits of Assam are similar to those Burma, being in rocks of Tertiary age. They are confin to a curved belt of country along the basins of t Brahmaputra and Surma, over some 800 miles from N. Assam through Kachar and Chittagong to the Arak coast. Only two fields of commercial importance a worked, at Digboi and Bappa Pung, about one mile apa in N.E. Assam, but comparatively little exploration h been done.—R. G. P.

Paraffin wax industry of Austria; Application of c in the ——. P. Porges. Z. angew. Chem., 1914, III., 41.

To enable Austrian lubricating oils to compete wi Russian and American oil the paraffin wax is separat as completely as possible. About 95% of the Austri works use the patented apparatus of Porges, Sing and Steinschneider, and produce 6500 wagon-loads purified wax per annum. The oils are gradually chill by passing them through a series of connected crystallising chambers surrounded by coils through which brine is pumped. The semi-solid mass from the chambers is pressed, usually in filter-presses, and the filtrate again partially chilled before being suitable for lubricants. The residue in the press, termed "*gatsch*" is usually submitted to dry sweating to expel the oil. A recent improvement has been the introduction of Pejzel's apparatus, in which the sweating vessels are mounted on trolleys which pass through a ventilated passage. After leaving the sweating vessels the wax is decolorised with sulphuric acid and "silicate." The system of moist sweating, which is little used, aims at utilising the hot liquor from the crystallising chambers. Fractional crystallisation of the wax is effected by chilling the chambers in stages. One part of the apparatus works at 0° C., a second at —5° to —7° C. and a third at —10° to —18° C.; and in a patent process of Pejzel and Porges each chamber is chilled so as to yield a paraffin wax of a definite m. pt.—C. A. M.

Hydrocarbons of Utah—A correction. C. Bardwell, B. A. Berryman, T. B. Brighton and K. D. Kuhre. J. Ind. Eng. Chem., 1914, **6**, 865—866.

Attention is called to certain inaccuracies in the original paper, chiefly in connection with the composition of the different products, but not affecting the abstract (this J., 1914, 15).—A. S.

Apparatus for the analysis of complex gas mixtures. Taylor. *See* XXIII.

Patents.

Coal-washing apparatus. E. G. Burks and N. Hayes, Birmingham, Ala. U.S. Pat. 1,112,976, Oct. 6, 1914; date of appl., Oct. 15, 1913.

The mud from coal-washing is discharged from a sluice into a filtering vessel having inner and outer perforated vertical walls with an intermediate filling of granular material. This vessel is placed in a tank having an overflow, and the overflow water is withdrawn from the tank by a pump and delivered to the sluice. A conveyor is provided for removing the material collected in the filtering vessel.—A. T. L.

Fuel-briquette composition. W. Loesch, Assignor to G. B. Storer, Chicago, Ill. U.S. Pat. 1,111,800, Sept. 29, 1914; date of appl., April 14, 1913.

A mixture of finely divided fuel, 100, cement, 25, finely divided clay, 5, potassium nitrate, 0·5, and water, 25 parts by volume, and if desired, coal oil 2 parts.—A. T. L.

Briquettes [of carbonaceous material]; Process for making —— using waste sulphite lye treated with sulphuric acid as binding agent. A. Richter. Ger. Pat. 275,832, Aug. 2, 1910.

Coal dust or other carbonaceous substance is mixed with a binding agent composed of waste sulphite liquor, sulphuric acid, and tar oils or similar oils, briquetted, and heated to 250°—270° C. to carbonise the binding agent.—T. F. B.

Gas retorts; Means for controlling the operation of ——. H. A. Carpenter and A. W. Warner, Sewickley, Pa., Assignors to Riter-Conley Manufacturing Co., Pittsburgh, Pa. U.S. Pat. 1,112,978, Oct. 6, 1914; date of appl., June 2, 1914.

In a retort which is charged and discharged at opposite nds, the charging and discharging tool is driven by an lectric motor controlled by circuit-closing devices at pposite ends of the retort.—A. T. L.

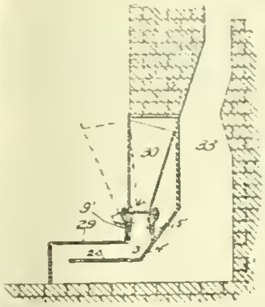
Producer gas generators. T. R. Wollaston, Manchester. Eng. Pat. 29,089, Dec. 17, 1913.

The roof of the producer chamber is formed by a boiler r vaporiser having Field tubes which project into the hot fuel. This boiler is slowly rotated or oscillated so as to stir the fuel and to promote the heating of the Field tubes. The steam passes with air through the jacketed casing of the producer and thence to the bottom of the fuel column. The steam may pass through an injector nozzle so as to force the air through the producer, or a blower may be used. The fuel is fed through a shoot passing through the gas-outlet pipe.—A. T. L.

Gas or vapour producers. F. C. L. Biddlecombe, Luton, Beds. Eng. Pat. 10,681 of 1914; date of appl., Oct. 20, 1913.

In apparatus in which partial combustion of liquid fuel is effected in order to convert the remainder of the fuel into a combustible gas or vapour, as described for example in Eng. Pat. 10,305 of 1913 (this J., 1914, 740) the capacity of the combustion chamber is varied, according to the rate at which gas is made, by means of a loose-fitting piston, which permits the flow of gas to the outlet but prevents the passage of the flame.—A. T. L.

Wood-gas generator and burner. W. L. Boxall, Perry, Cal. U.S. Pat. 1,111,129, Sept. 22, 1914; date of appl., Aug. 10, 1909.



The apparatus, which is fitted into a fire-place opening for heating purposes comprises a combustion chamber, 3′, having a radiating front, 29, and divided by a horizontal partition, 20, into upper and lower passages, the lower passage leading to the flue, 33. Air is admitted through openings at 9′, in a pivoted throat-piece, 15′, which carries the feeding hopper, 30, and rests normally on the sloping wall, 4′, of the combustion chamber, so as to prevent the escape of smoke. For charging, the hopper is tilted forwards as shown in broken lines.—A. T. L.

Gas producer apparatus. J. A. Herrick, Newark, N.J. U.S. Pat. 1,112,534, Oct. 6, 1914; date of appl., Dec. 30, 1912.

The producer has a rotatable body portion, and a heavy inclined poker projecting through an universal joint in the side wall of the fixed upper portion. The lower end of the poker fits into any one of a number of recesses in a central support within the producer, and mechanism is provided for adjusting the poker to any desired position. —A. T. L.

Gas producer. E. A. W. Jefferies and G. H. Isley, Assignors to The Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,112,702, Oct. 6, 1914; date of appl., Aug. 23, 1909.

The producer has a water-sealed ash-pit, which carries a vertical central tuyère with hollow radial arms arranged in a horizontal plane and presenting vertical surfaces to the fuel column. The air enters the fuel column through orifices at the upper edges of the radial arms. The tuyère and arms are rotated to stir the fuel, and horizontal bars are arranged in the producer, at a higher level than the stirring arms, to prevent rotation of the fuel.—A. T. L.

Gas washer. J. F. M. Patitz, Milwaukee, Wis., Assignor to Allis-Chalmers Manufacturing Co. U.S. Pat. 1,112,381, Sept. 29, 1914; date of appl., Feb. 10, 1912.

The washer comprises a casing containing superposed sets of rotating fan blades, carried by a vertical shaft, the gas being directed outwards through each set of blades. Washing liquid is sprayed into the casing towards the fan blades and is caused to flow outwards and then inwards as a continuous film enclosing the discharge of the rotating fans, so that the gas passes along and through the film of liquid.—A. T. L.

Petroleum hydrocarbons; Converting higher boiling into lower boiling ——. G. W. Gray, Houston, Texas, U.S.A. Eng. Pats. (a) 17,838 and (b) 17,839, Aug. 5, 1913. Under Int. Conv., Jan. 23, 1913.

(a) The oil is heated in the presence of anhydrous aluminium or ferric chloride to not substantially above the "end-boiling-point" of naphtha, and the vapours are condensed. A petroleum distillate free from naphtha products, when heated with 5% of aluminium chloride at 325°—350° F. (163°—177° C.) yields 70—80% of naphtha suitable for motors. If the temperature be raised to 550°—600° F. (288°—316° C.) the distillate consists of naphtha and burning oil which can be afterwards separated. The process may also be used for obtaining light oils from burning and lubricating oils and from crude oil. (b) The distillation is carried out between 400° and 600° F. (204° and 316° C.), and the vapours are passed through a cooling chamber where the burning oil is condensed, the naphtha vapours passing on to a separate condenser. The burning oil may be returned to the still.—A. T. L.

Oil distillation. S. M. Herber, Inza, Mo. U.S. Pat. 1,111,580, Sept. 22, 1914; date of appl., Feb. 9, 1914.

To increase the yield of lower-boiling fractions, the oil is mixed with about one-seventh its bulk of lime and distilled in a current of air or in the presence of water or steam, with or without air.—A. T. L.

Oxygeniser in connection with combustibles; Composition of matter to be used as an ——. A. Morin, L. Hamon, and E. Hess, Montreal. U.S. Pat. 1,112,547, Oct. 6, 1914. Date of appl., Nov. 22, 1913.

See Eng. Pat. 27,648 of 1913; this J., 1914, 635.—T. F. B.

Gases; Apparatus for purifying ——. K. Bomhard, Berlin. U.S. Pat. 1,112,970, Oct. 6, 1914. Date of appl., Sept. 19, 1911.

See Fr. Pat. 433,801 of 1911; this J., 1912, 220.—T.F.B.

Mineral oils; Process of treating ——. J. Dehnst, Halensee, Germany. U.S. Pat. 1,112,602, Oct. 6, 1914. Date of appl., April 17, 1906.

See Ger. Pat. 178,771 of 1905; this J., 1907, 863.—T. F. B.

Means in combination with hydrogen producing plant for regulating fluid pressures therein. Eng. Pat. 16,893. *See* VII.

Carbon dioxide gauge. U.S. Pat. 1,111,565. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Hardwood distillation; Possibilities of —— on the Pacific Coast. R. C. Palmer. Met. and Chem. Eng., 1914, **12**, 623—626. (See also this J., 1914, 345.)

The yields of charcoal, acetate of lime and crude wood alcohol obtained in the laboratory from tanbark oak and California black oak (the most promising of the hardwoods available on the Pacific coast) compared very favourably with those from the hardwoods (beech, birch and maple) used in other localities; the results of large-scale tests were less satisfactory, but still favourable to commercial operation. Under present market conditions it would not be advisable to establish more than one or two small plants in California.—W. E. F. P

Carbons for electric lighting. Board of Trade Bulletin No. 82.

Can be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, London, E.C.

Patent.

Arc-light electrode. I. Ladoff, Cleveland, Ohio, Assignor to W. D. Edmonds, Boonville, N.Y. U.S. Pat. 1,112,458, Oct. 6, 1914. Date of appl., June 1, 1911.

Electrodes for producing flaming arcs are made principally of carbon together with calcium titanate and an organic salt of titanium, a titanium-halogen compound, or an alkali titanofluoride.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Guyot tar. Petkow. *See* XX.

Patents.

Pitch compositions; Toughened ——. E. L. Manhayfer, St. Louis. U.S. Pat. 1,112,817, Oct. 6, 1914. Date of appl., Dec. 13, 1910.

Pitch is mixed with kieselguhr in sufficient quantity to raise its melting point considerably, without destroying its plasticity at normal temperatures. The melting point of the pitch may be raised 20°—25° F. (11°—14° C.) by addition of 15% of kieselguhr.—T. F. B.

1.2-Dihydroxybenzene-4.6-disulphonic acid; Process for preparing ——. Saccharinfabr. A.-G. vorm. Fahlberg, List und Co. Ger. Pat. 276,273, June 3, 1913.

op-Phenoldisulphonic acid is treated with chlorine or bromine in acid solution, and the *o*-halogen-phenoldisulphonic acid is heated with dilute alkali under pressure, below 200° C., to convert it into 1.2- dihydroxybenzene-4.6-disulphonic acid.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Colours and dyestuffs; Export of ——. *Issue of special licences.* Board of Trade J., Oct. 29, 1914. [T.R.]

With reference to the Order of Council dated 8th September, 1914, which prohibited the exportation from the United Kingdom of dyes and dyestuffs obtained from coal tar, the Board of Trade announce that, on their recommendation, licences have been granted to certain firms to export some or all of the colours and dyestuffs specified in the appended schedule, on the express condition that the reasonable requirements of consumers in the United Kingdom in respect of such colours and dyestuffs are first supplied. Any British consumers of these colours and dyestuffs who are unable to obtain the supplies they require should communicate with the Board of Trade.

Cross Dye Blacks, FG, 70823, T Extra 20% strong, BF, BX 20% strong, RX 20% strong and TF; Sulphur Bronze 136; Sulphur Browns 4R, 2D, 2R and 731; Sulphur Yellows Y and R; Sulphur Drab N; Methyl Violets ST and Base 2B; Methyl Blue 2B; Magenta Powder FA and Crystals FA; Methylene Blue ZF; Auramine O and O Conc.; Cerise FDA; Green Crystals A and Y; Bismarck Brown R 100s, Y 100s, Concentrated, and R Concentrated; Chrysoidine R Powder, Y Powder, and Crystals; Nigrosine D, G, and P; Soluble Nigrosine X; Nigrosine 32391; Induline A and B; Soluble Blue A, B, and C; Spirit Blue and Spirit Blue 2B; Thionol Yellow G; Thionol Orange L; Thionol Brown G conc.; Thionol Khaki I; Thionol Browns O and R; Thionol Dark Green; Thionol Brilliant Greens 6GX conc., 4GX conc., and GX; Thionol Green 3B; Thionol Purple B conc.; Thionol Corinth GX and BLX; Thionol Brilliant Corinth RX; Cachou R, 2R, and OX; Thionol Blues and Blacks, Leather Brown LX; Dianol Fast Yellow AR; Dianol Brilliant Red X; Dianol Dark Green N; New Coccine; Phosphine; Leather Orange F; Wool Scarlets 390 and

285; Dianol Oranges; Prune 516; Wool Black 3015; Fast Milling Black B; Era Chrome Blacks; Era Crome Browns M and B; Chrome Red Brown; Chromotrope M; Archelline 2B; Ponceau R and 2R; Orange 4GB; Chrome Green Y; Alizarin Yellow 3G; Crumpsall Yellow YYFP.

Patents.

Vat dyestuffs of the naphthalene series; Preparation of ——. M. Kardos. Ger. Pats. (A) 276,357, June 14, 1913, and (B) 276,358, June 26, 1913.

(A) Naphthalene-1.8-dicarboxylic acid imine, or the condensation product from acenaphthenequinone and hydroxylamine, is fused with an alkali hydroxide. The products are claret or red vat dyestuffs. (B) The dyestuffs described above are treated with fuming nitric acid, and the nitro compounds are dissolved in sodium hydroxide or carbonate solution and reduced with alkaline reducing agents. The resulting compounds dye cotton blue, blue-violet, and grey-violet shades.—T. F. B.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Silk in Madagascar. J. d'Agric. trop., 1914, 14, 89. Bull. Imp. Inst., 1914, 12, 487.

Both the native silkworm or "landibe" (*Borocera Madagascariensis*) and the mulberry silkworm (*Bombyx mori*) are used by the natives of the centre of the island. The "landibe" lives in natural forests of *Uapaca clusiacea* or in plantations of *Dodonea Madagascariensis* and *Cajanus ndicus*, and produces two harvests a year of brown or grey cocoons. The silk, which is comparable with tussah silk, cannot be reeled, but is carded and spun. The rearing of the mulberry silkworm is increasing. The ilk is used locally and is not yet exported. A station for he study of the silkworm and production of disease-free seed has been established at Nanisana.—R. G. P.

Textile industry; Application of low temperatures in the ——. F. Erban. Z. angew. Chem., 1914, 27, III., 41.

In the preparation of flax for spinning, the "straw" is dried for 50 to 80 hours in the sun, then cooled to —4° C., and the bast fibres separated while in a frozen condition (see this J., 1911, 18). In Ahnert's mercerisaion process the yarns are impregnated with hot lye (25° B., sp. gr., 1·21) and then chilled (see Kirchbacher, his J., 1911, 20). Artificial cold is employed in Schultze's process of obtaining solid alkali hydrosulphites from solutions. In finishing fabrics various machines for applying low temperatures are in use to shorten processes, and to increase the amount of moisture fixed by the fibres. —C. A. M.

Textile machinery. Board of Trade Bulletin. No. 86.

This Bulletin can be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Patents.

Celluloid or like substitutes; Manufacture of ——. L. L. T. Labbé, Asnieres, France. U.S. Pat. 1,112,297, Sept. 29, 1914. Date of appl., June 16, 1911.

See Fr. Pat. 430,035 of 1911; this J., 1911, 1308.—T.F.B.

Pulp from waste papers; Process for the recovery of ——. J. M. Burby, Astoria, Assignor to The Pembee Co., New York. U.S. Pat. 1,112,887, Oct. 6, 1914. Date of appl., June 15, 1911.

See Fr. Pat. 444,703 of 1912; this J., 1912, 1075.—T.F.B.

Process for making briquettes [of carbonaceous material], using waste sulphite lye treated with sulphuric acid as binding agent. Ger. Pat. 275,832. *See* IIa.

Application of low temperatures in the textile industry. Erban. *See* V.

Hydrosulphites and formaldehyde-sulphoxylates. Wild. *See* VII.

Patents.

Silk; Process for weighting —— by means of zirconium compounds. E. Stern. Ger. Pat. 276,423, Feb. 9, 1913.

The tetrahydrate of zirconium sulphate, $Zr(SO_4)_2.4H_2O$, is used for weighting silk, either alone or in conjunction with other weighting substances.—T. F. B.

Colours; Method and means of recording, matching, or devising new shades of ——. G. and W. Parsons, London, and A. W. Coker, Sutton, Surrey. Eng. Pats. 20,093 and 30,096, Sept. 5 and Dec. 31, 1913.

A machine of the rotating disc type, the turntable being operated by an electric motor and the coloured discs being slotted to enable them to fit adjustably over one another. A modification consists in the use of a single colour disc over which is placed a heart-shaped cam (of white for instance) which combination when rotated shows the mixed shade in gradually increasing strength from the centre outwards. Holes are provided in the turntable which during rotation set up suction, thus keeping the coloured discs flat. Convenient means of measuring the areas are provided.—J. B.

[*Fireproofing.*] *Treatment of cotton and cotton goods and other combustible substances to render them permanently less inflammable.* W. H. Perkin, Oxford, S. Bradbury, Ashton-on-Mersey, and Whipp Bros. and Tod, Ltd., Manchester. Eng. Pats. (A) 17,814, 20,971, and 24,088, Aug. 5, Sept. 17, and Oct. 24, 1913, and (B) 17,815 and 20,972, Aug. 5 and Sept. 17, 1913.

(A) The goods are impregnated with a soluble salt of a metal, the oxide or hydroxide of which is capable of acting as an acid, and, after drying, the deposited salt is fixed by treatment with a prepared atmosphere containing a gas (*e.g.*, carbon dioxide or sulphur dioxide) which is capable of rendering the deposited salt insoluble. The fixing atmosphere is preferably moist and the temperature is preferably high, *e.g.*, the fixing gas may be admitted into an ordinary ager. (B) The use of an alkali aluminate as impregnating salt and of carbon dioxide as the fixing gas is specially claimed. Good results are obtained on flannelette by impregnating with a solution of sodium aluminate of 30° Tw. (sp. gr. 1·15) and ageing in an atmosphere containing 10% or more of carbon dioxide and sufficient steam to leave the goods slightly wet on emerging. (See also Eng. Pats. 8509 and 9620 of 1902 and 24,222 of 1903; this J., 1903, 623, 551; 1904, 981.)—J. B.

Waterproof fabric and the like; Manufacture of —— and means for use therein. T. W. Jacobs, jun., London. Eng. Pat. 26,172, Nov. 14, 1913.

The fabric is passed over and under guide rollers through a tank containing the waterproofing liquid, such as a mixture of vaseline, 100; paraffin wax, 100; naphthalene, 4; carbolic acid, 12; and vegetable black, 3 parts, and then between steam-heated squeezing rollers which remove the excess of liquid, and bring about a thorough impregnation of the fabric. The pressure and the temperature of the rollers should be kept approximately constant. —E. W. L.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Phosphoric acid and phosphates; Alcohol in the manufacture of ——. P. J. Fox. J. Ind. Eng. Chem., 1914, **6**, 828—829.

To extract phosphoric acid from phosphate rock it is suggested that treatment with the requisite quantity of sulphuric acid of 50° B. (sp. gr. 1·53) be followed by leaching with denatured alcohol, the residue being filter-pressed. A relatively pure alcoholic solution of phosphoric acid would thus be obtained. In laboratory tests with calcium phosphate, an extraction of 99·2% of the phosphoric acid was obtained with 95% alcohol and 98·7% with 50% alcohol.—A. S.

Potash; Waste of ——. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 374—375.

Co-operation is suggested for the collection and incineration of many waste marine and land plants such as furze, hedge-clippings, bracken, etc., as a source of potassium salts. The following figures give the potash content of the ashes: *Fucus vesiculosus*, *F. serratus*, 4—5%; *F. nodosus*, 13%; oarweed, *Laminaria saccharina*, 15%; *Enteromorpha intestinalis*, 7%; *E. compressa*, 10%; *Ulva latissima*, 4%; *Zostera marina*, 9·5%; bracken, 60%; *Boletus edulis*, 50—57%; *Agaricus velutipes*, 78%; the heath mosses *Hypnum Schreberi* and *H. splendens* 28—30%; hop bine, 25%; groundsel, *Senecio vulgaris*, 43·5%; common broom, 33%; willow bark, 24%; sweet chestnut bark, 20%; common furze, 28%; *Euphorbia amygdaloides*, 39%; Virginian creeper leaves 25%.—F. Shdn.

Clay filters and certain salt solutions; The action between ——. W. B. Hicks. J. Ind. Eng. Chem., 1914, **6**, 829—831.

Various saline solutions were filtered through 8-in. Pasteur-Chamberland water filters. Little or no change was produced in the boric acid content of borate solutions; there was a decrease of 0·2—0·5% in the concentration of alkali sulphate and chloride solutions, of 0·5% in *N*/10 and 8% in *N*/1000 alkali carbonate solutions. The filters were dissolved appreciably by ammonium chloride solutions.—A. S.

Hydrosulphites and formaldehyde-sulphoxylates. E. Wild. Chem.-Zeit., 1914, **38**, 928.

The iodine method of Baumann, Thesmar and Frossard is recommended for the estimation of the sulphoxylate, but in the author's opinion a quick and simple method of analysing hydrosulphites is still lacking. (See Bosshard and Grob; this J., 1913, 485.)—J. B.

Ozone; Action of —— *on inorganic sulphur compounds.* E. H. Riesenfeld and T. F. Egidius. Z. anorg. Chem., 1914, **85**, 217—246.

The action of a stream of strongly ozonised oxygen on solutions of sulphur compounds was investigated. Alkali sulphides, normal or acid, gave thiosulphate and sulphite, with some hydrosulphite; thiosulphate, neutral or alkaline, gave sulphate, dithionate and sulphate, with small quantities of polythionate; sulphite gave principally sulphate, with some dithionate. The end-product in all cases was sulphate. Whilst sulphur compounds at a low stage of oxidation (sulphites, &c.) take up ozone as a whole, analogous metallic compounds (ferrous, manganous, and like salts) take up 1 atom of oxygen, a molecule of oxygen escaping.—O. E. M.

Lead acetate, lead oxide, water; Equilibrium in the system ——. R. F. Jackson. J. Franklin Inst., 1914, **178**, 492—493.

To obtain a basis for investigating the clarification of raw sugar, a study was made of the basic acetates of lead from the standpoint of the phase rule. The analyses were made by measuring the volume of standard acid neutralised by the basic lead, and the volume of acid or of sodium oxalate required for total precipitation of the lead. The basic acetates were prepared by the interaction of normal lead acetate and lead hydroxide. The solid phases capable of existence were found to be three. Normal lead acetate, $Pb(C_2H_3O_2)_2,3H_2O$, consists of monoclinic prisms; it is stable in equilibrium with its own solutions, and its solubility increases rapidly in solutions of increasing basicity. Its solubility in neutral solutions is 35·5%. Tetra-lead monoxyhexa-acetate, $3Pb(C_2H_3O_2)_2,PbO,3H_2O$, crystallises in minute needles, is very soluble in water, and forms highly refracting solutions of sp. gr. 1·93—2·28. It is unstable in contact with its own solution. Its solutions contain at the extremes of saturation 15·89% PbO, 48·95% $Pb(C_2H_3O_2)_2$, and 24·74% PbO, 49·21% $Pb(C_2H_3O_2)_2$. Tri-lead dioxy-diacetate, $Pb(C_2H_3O_2)_2,2PbO,4H_2O$, consists of minute imperfect needles; it is capable of existing in contact with its own solutions, in which case its solubility is 13·3%. Its saturation curve is very long. The extremes of solubility are 7·4% PbO, 4·8% $Pb(C_2H_3O_2)_2$, and 24·74% PbO, 49·21% $Pb(C_2H_3O_2)_2$.—J. H. J.

Manganese sulphide; Heat of formation of ——. S. Wologdine and B. Penkiewitsch. Comptes rend., 1914, **158**, 498—499.

The oxidation of manganous sulphide resulting in the formation of Mn_3O_4 and sulphurous and sulphuric acids gave as a mean value of somewhat varying results 70·535 cals. for the molecular heat of formation of the sulphide. A second method consisted in the ignition of a compressed pastille of manganese and sulphur in a calorimetric bomb in an atmosphere of nitrogen by means of a mixture of aluminium and potassium chlorate and a fuse of guncotton. It gave a value of 62·901 cals. per mol. as the mean of a number of concordant results.—G. F. M.

Felspar supply of the United States. Watts. *See* VIII.

Use of washers and coolers with sulphur ovens, and [*determination of*] *the sulphuric acid content of the oven gases.* Pellet. *See* XVII.

Chief cause of the loss of sulphuric anhydride and chlorine by incineration of substances containing these constituents. O'Sullivan. *See* XXIII.

Barytes in Canada. Oil, Paint, and Drug Rep, Oct. 12 1914. [T.R.]

The barytes mines in Cape Breton will shortly be able to supply the needs of Canada, whilst other sources will produce sufficient quantities for export.

Fluorspar in the United States. Oil, Paint, and Drug Rep., Oct. 12, 1914. [T.R.]

The increase in the home production and the imposition of a tariff on fluorspar in 1909 have resulted in a decrease in the American imports to 22,682 short tons in 1913 compared with the 115,580 tons produced. The imports came almost entirely from Great Britain and amount to over 55% of the total English production. The open-hearth steel process absorbs about 80% of the amount produced.

Patents.

Hydrogen producing plant; Means in combination with —— *for regulating fluid pressures therein.* J. Dempster, Manchester. Eng. Pat. 16,893, July 16, 1914.

In the production of hydrogen by the action of steam on oxidisable material, with alternate de-oxidation by a current of reducing gas (water-gas), a pressure-regulating device is provided to prevent leakage of reducing gas into the hydrogen or steam connections by ensuring a higher pressure in these than in the reducing gas mains. A vessel is divided into two intercommunicating compartments which contain water; one compartment is

in connection with the water-gas inlet main and is provided with an overflow passage, whilst, in the other compartment, water forms a seal between the hydrogen outlet main and the hydrogen scrubber. Any increase of pressure in the water-gas inlet main, acting upon the surface of the water in the first compartment, increases the depth of seal in the second compartment and necessitates therefore a corresponding increase of pressure in the hydrogen outlet main, and in the supply of steam.
—F. Sodn.

Catalysts; Manufacture of ——. A. Schwarcman, Assignor to Spencer, Kellogg and Sons, Inc., Buffalo, N.Y. U.S. Pat. 1,111,502, Sept. 22, 1914; date of appl., Feb. 4, 1914.

A hydrated sesquioxide, *e.g.* $Al_2(OH)_6$, is precipitated by an alkali, washed free from soluble matter and treated with a dilute solution of a compound of a metal of the platinum group (preferably palladium) containing as much metal as will be absorbed by the $Al_2(OH)_6$. The precipitate is collected and dried.—W. H. C.

Sulphuric acid; Chamber used in the manufacture of ——. W. G. Mills and C. T. Packard, Assignors to E. Packard and Co., Ltd., Ipswich. U.S. Pat. 1,112,546, Oct. 6, 1914. Date of appl., March 21, 1914.

See Eng. Pat. 12,067 of 1913; this J., 1914, 692.—T. F. B.

Nitrate of lime; Process of effecting solidification of fluid ——. M. Scharff, Ludwigshafen, Germany, Assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,112,722, Oct. 6, 1914. Date of appl., July 3, 1912.

See Fr. Pat. 445,826 of 1912; this J., 1912, 1179.—T. F. B.

Hydrogen; Process of producing ——. C. Bosch and W. Wild, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S Pats. 1,113,096 and 1,113,097, Oct. 6, 1914. Dates of appl., Oct. 29, 1913.

See Fr. Pat. 459,918 of 1913; this J., 1914, 24.—T. F. B.

VIII.—GLASS; CERAMICS.

Refractories; Needs of the glass manufacturer in the way of ——. C. W. Berry. Trans. Amer. Ceram. Soc., 1914, **16,** 101—108.

Resistance of tank blocks and glass-pots to the action of fluxes depends more upon physical structure than on chemical composition. A block should possess sufficient density to prevent the penetration of fluxes. It should dissolve slowly in the glass without causing "stones" and the wearing surface should remain smooth. Pure non-plastic clays which are attacked only slightly by fluxes must be introduced in a very fine condition, as otherwise the plastic binding clay will dissolve, allowing the refractory clay to enter the glass and form "stones." Blocks high in silica, *e.g.*, where free silica has been added to obtain 77% SiO_2 in the finished product, are quickly destroyed, as also are mixings high in alumina. High silica also tends to increase porosity. It is not advisable to introduce "grog" made from used pots, as the material has absorbed fluxes which will cause a honeycombed surface. The greatest wear on a pot occurs during the first four melts; after the fifth, the action diminishes as the pot becomes nearly vitrified. A pot which is suitable in composition for plate glass may not answer for lead and other glasses made in closed pots.—H. H. S.

Soda-lime glasses; The limits of proportions of ——. F. Gelstharp and J. C. Parkinson. Trans. Amer. Ceram. Soc., 1914, **16,** 109—116.

Soda ash glasses can only be made successfully with a limited proportion of lime, *e.g.*, $1CaO:2Na_2O$. To obtain satisfactory glasses containing more than 8% CaO, sodium sulphate must be used. Glasses containing soda in excess of 22% of the silica content are not likely to be strong and durable; for plate glass, the soda content should be much lower. The whole field of soda lime silicates may be divided into: (1) opaque basic slags and infusible mixtures of silicates and bases; (2) mixtures giving transparent glasses only on very rapid cooling, otherwise opaque crystalline masses; (3) transparent glasses proper, including those of technical importance; (4) mixtures giving opalescent opaque glasses on slow cooling. The authors made glasses of the definite silicates $2Na_2O,SiO_2$; Na_2O,SiO_2; $Na_2O,2SiO_2$; but a mixture of the composition, $Na_2O,3SiO_2$, gave a melt containing suspended silica which dissolved slowly, to form probably a solid solution of silica in the bisilicate.—H. H. S.

Ruby colour in glass; Notes on the development of ——. A. E. Williams. Trans. Amer. Ceram. Soc., 1914, **16,** 284—306.

Ruby glass is obtained by using as colouring agent copper, gold, selenium, or flowers of sulphur; the metals being usually found to be in suspension as colloids. Recipes culled from the literature of the subject are given for gold, selenium and sulphur rubies, but the author's own experiments refer to copper ruby glass. This was formerly made by the process of flashing, which consists of placing a very thin layer of coloured glass on a surface of colourless glass of normal thickness; special skill being required to blow the layer to uniform thickness in order to obtain uniform colour. At present, however, ruby glass is made by pressing in moulds and reheating. The colour should not be developed till the glass is reheated. Highly fluid glasses are found to "colour out" quickly, viscous glasses slowly. Substitution of lead or soda for lime increases rapidity of colour development, lead more so than soda. High silica content (4—4·5 mols.) is necessary to give sufficient viscosity, and to obtain good colour; low silica tends to produce brown or black colours and opacity. With high silica in lime-potash glasses there is a tendency to streakiness, which can be reduced by small quantities of lead oxide, and by re-melting. Iron and manganese are detrimental to a good red colour. Density of colour is apparently increased by increase in temperature. The following formulæ were found to be most suitable for a good ruby glass, 1% of cream of tartar being added:—

Equivalents.					
Na_2O	0·102	—	—	0·100	0·100

—H. H. S.

Glass. Similarity between aqueous and glass solutions of gold. Effects of various temperatures on coloured glass. A. Silverman. Trans. Amer. Ceram. Soc., 1914, **16,** 547—550.

The colour-changes from yellow gold chloride solution to red colloidal solution of gold, and then to brown precipitate and blue supernatant colloidal solution, which occur on addition of potassium carbonate and formaldehyde and subsequent boiling with oxalic acid, may be reproduced in solid solution in glass. Gold chloride solution was sprinkled on sand which was then added to the batch mixing of a Pb-Na-K silicate glass. Stannous oxide served as reducing agent, and the third stage was effected by re-heating.

As certain coloured glasses were found to be much darker at high than at the ordinary temperature, the effect of immersion in liquid air was observed. Selenium ruby, black at high temperatures, was yellow to orange in liquid air. No perceptible change took place with blue and green glasses, but most red and yellow glasses and also potassium bichromate and sulphur became lighter in colour. Return to the ordinary temperature restored the original colour.—H. H. S.

Fluorides as opacifiers [*clouding agents for glass and enamels*]. J. B. Shaw. Trans. Amer. Ceram. Soc., 1914, **16**, 577—579.

Opacity may be produced in glass by fluorides without the presence of alumina. Different heat treatment will modify the products from any given fluoride mixing. —H. H. S.

Clay; Effect of some electrolytes on ——. R. Back. Trans. Amer. Ceram. Soc., 1914. **16**, 515—546.

The clays were used in the physical conditions of plastic mass, thick paste, creamy slip, and 5% aqueous suspension. The effect of added electrolytes was studied with regard to volume shrinkage in drying of the plastic mass, water content of pastes just fluid enough to flow, and viscosity, flocculation and volume shrinkage of slips. Great precautions were found necessary to eliminate error in drying the clay, making it plastic and moulding into briquettes, especially with regard to the time factor. The ratio of volume shrinkages of a ball clay and a kaolin in their best working consistence bore no relation to the ratio of the percentages of water used. These varying shrinkage and pore-water volume relations are attributed to an arrangement of the clay particles effected by the reagents, or to a change in their power of retaining water at 110° C. Some electrolytes, *e.g.*, $Ca(OH)_2$ and $Ba(OH)_2$, in small quantities (0·05—0·075%) act as deflocculators, but greater concentrations produce distinct flocculation. The cause of such dual behaviour is to be sought in dissociation phenomena and changes in surface tension of the liquid medium. Caustic soda and potash are vigorous deflocculating agents at all concentrations, although a temporary thickening may be caused by the presence of lime. The coagulating power of neutral salts ($NaCl$, $CaCl_2$, $AlCl_3$) and the rapidity of coagulation increases with the valency of the cation; neutral salts, as well as acids and alkalis, have a decided influence on the shrinkage and viscosity of clays. The smallest quantities of electrolytes used showed an effect on the fluidity or stiffening of clay paste. Electrolytes that cause flocculation in a clay system may be employed to reduce cracking and excessive shrinkage in the drying of troublesome clays. For casting slips, caustic soda or potash or sodium silicate or carbonate may be used, the volume shrinkage being reduced by one-third. The structure of a cast piece seems more compact and stronger when the correct quantity of electrolyte is used, but excess weakens the ware. As lime and alkalis affect the "malachite green" used in the dye-absorption method of estimating colloids, the Rodenwald-Mitscherlich hygroscopicity method is preferable.—H. H. S.

Weathering of fireclays in the manufacture of face brick and paving block. L. B. Rainey. Trans. Amer. Ceram. Soc., 1914, **16**, 405—408.

The practice of causing clay to "weather" for about four weeks after being mined is regarded as unnecessary, because insufficiently prolonged to bring about any real mineralogical change. Blocks made from the "green" clay tended at first to crack in drying, a difficulty which was overcome by addition of ¼ lb. of salt to each wheel-barrow of clay as it was fed to the pans. The fired ware required longer cooling, *viz.*, 6 days instead of 5. Its resistance to disintegration by the "rattler" test was only 1% inferior (18 : 19) to that of ware made from weathered clay, whilst the colour was brighter.—H. H. S.

Clay; Data on effect of varying compression loads applied to —— *in the plastic condition.* C. W. Parmelee. Trans. Amer. Ceram. Soc., 1914, **16**, 194—200.

In view of the divergence of opinion between Seger and some later writers (see Rept. N.J. Geol. Surv., VI, 260; Missouri G.S., XI, 459; G.S. of Iowa, XIV, 206) as to the effect of re-pressing clay, trial pieces were subjected to compression in a cylindrical die, 15 cm. long and 5·3 cm. in diameter, the pressures ranging up to 50,000 lb. on the whole surface. The results uphold Seger's contention that re-pressing has little, if any, effect upon the density of plastic clay. There is certainly no relation between the magnitude of the compression load and porosity. Any variation in volume of pores is to be attributed to lack of homogeneity in preparing the plastic mass. It follows that in the repressing of brick, pressure used in excess of what is necessary to cause the clay mass to fill the die is wasted energy, and may have the undesirable tendency of weakening resistance to crushing.—H. H. S.

Clays; The compression, tensile and transverse strength of some —— *in the dried state.* A. V. Bleininger and W. L. Howat. Trans. Amer. Ceram. Soc., 1914, **16**, 273—283.

Any strength test of dried clay is regarded as constituting, at best, but a rough and indirect estimate of plasticity. On the other hand, such tests have a practical value in connection with the drying of clays and their bonding power on sand. Tests with mixtures of clay and standard sand are not comparable with those without sand, on account of this bonding power and the change in drying conditions. The clay-sand trials are preferred, particularly with ball clays and plastic fireclays. The transverse test is regarded as more reliable than the tensile test, which is in turn better than the compression test. In all cases, variations from the average are so great that no meaning can be attached to the results until 20 specimens have been broken.—H. H. S.

Clay; The plasticity of ——. N. B. Davis. Trans. Amer. Ceram. Soc., 1914, **16**, 65—79.

Plasticity in clay has been variously attributed to the structure of the particles, to the presence of aluminium silicates containing chemically combined water of hydration, to molecular attraction between particles (Grout, 1905), and to the influence of colloidal matter (Schloesing, 1874). The colloidal theory is regarded as the most probable, and as capable of embracing the others. Organic colloids are very numerous; thirty-four, resulting from decomposition of vegetable and animal organisms, have been identified in soils (see U.S. Bureau of Soils, Bulls. 53, 74, 75). They are present as emulsion-colloids, and protect inorganic colloids—silicic acid, and aluminium and iron hydroxides—from mutual coagulation. The process of decomposition of a mineral such as orthoclase is considered to be essentially one of hydration, with a loss of silicic acid sols at each step, thus: $KAlSi_3O_8+HOH=KOH+HAlSi_3O_8$; $HAlSi_3O_8-SiO_2=HAlSi_2O_6$, pyrophyllite; which by further loss of silica becomes kaolinite and then diaspore. Apart from their protective influence, organic colloids and adsorbed salts increase plasticity by raising the viscosity of the water-film round the particles. The finer the grain of clay, the more chance for colloidal material to form. The longer the clay is subjected to the solvent action of water, the more colloids are formed. Binding power and shrinkage depend on the structure of the grain and on the nature of the emulsion colloids. —H. H. S.

Plasticity method; A study of the Atterberg ——. C. S. Kinnison. Trans. Amer. Ceram. Soc., 1914, **16**, 472—486.

Atterberg's method for measuring plasticity (see International Reports on Pedology, 1911; also this J., 1910, 629) is based upon the varying physical behaviour of clays with different water contents. He classifies the condition of a clay mixed with varying (progressively decreasing) amounts of water into five different states as follows: (1) The upper limit of fluidity, or the point where the clay slip flows as water; (2) the lower limit of fluidity, or flow, where two portions of the clay mass can barely be made to flow together when placed in a shallow dish and sharply rapped; (3) normal consistence, when clay is most workable, is no longer sticky and will not adhere to metal; (4) the rolling limit, at which clay can no longer be rolled into so-called threads between the hands and the surface on which it may rest, and which is the lower limit of the workable condition; (5) the point at which damp clay will no longer hold together when subjected to pressure. The second and third of these conditions define the working range of clay, and it is Atterberg's contention that the wider this range the more plastic is the clay. If the water content corresponding to each of these conditions be expressed as a percentage of the weight of dry clay, the "plasticity number" is the difference between the resulting figures; the higher its value the more plastic is the clay. It is found, however, in the case of loams and of clays rich in humus that normal consistence (3) is higher than flow-limit (2), and therefore two types of plasticity must be recognised, viz., sticky and non-sticky plasticity. Failure to appreciate this distinction is considered by Atterberg to be the cause of failure of many older methods for determining plasticity. The method was tried by the author on twenty American clays of various types, and was judged from practical experience to be no more accurate than that based on volume shrinkage. No method yet known entirely coincides in its results with those of practical experience, but a collation of the best reveals the facts with fair accuracy.—H. H. S.

Pottery scrap clay; Note on the restoration of plasticity to ——. J. Minneman. Trans. Amer. Ceram. Soc., 1914, **16**, 96—97.

Unfired scrap clay, found to be less plastic when re-blunged and re-pressed, may be restored by the addition of electrolytes which coagulate clay slips. Hydrochloric acid, magnesium sulphate, calcium sulphate and vinegar were used on a commercial scale, in amounts varying from 0·05 to 0·1%, the addition being made in the blunger. Magnesium sulphate (0·07%) was found to be most satisfactory, and has been used for several years. The restored plasticity is equal to the original.—H. H. S.

Viscosity of some shales at furnace temperatures. G. H. Brown. Trans. Amer. Ceram. Soc., 1914, **16**, 571—576. (See also Bleininger and Teetor, this J., 1914, 79.)

Test pieces burned to 850° C. were suspended vertically from fireclay grids in the kiln, and loads were applied by hanging to the lower ends fireclay weights equivalent to a tension of 5 lb. per sq. inch of cross-sectional area. Reference marks four inches apart were made on each piece. Seven burns were conducted, the finishing temperatures being 1020°, 1050°, 1090°, 1100°, 1130°, 1150 and 1170° C. respectively. A striking difference in the viscosities of shales during vitrification was evident. As a general rule, a shale or clay maintaining a high viscosity during vitrification is to be preferred to one which is subject to a sudden drop in viscosity: except when, as is found in very silicious samples, the former produces a ware of inferior strength and toughness.—H. H. S.

Felspar supply of the United States. A. S. Watts. Trans. Amer. Ceram. Soc., 1914, **16**, 80—95.

The demand for pure felspar being greater than European sources can supply, the author recounts the location and extent of felspar deposits (apparently pegmatite) in the United States east of the Mississippi River. The influence of the methods of mining and grinding upon the quality of the finished product is shown by the good reputation of Maine felspars, which are not naturally very pure on account of a quartz content which cannot be eliminated. Analyses given of American spars show variations in alkali content from 8 to 16%. The chief states concerned are Maine, Connecticut, New York, and Pennsylvania. In the last-named, the largest deposit of soda felspar in the world was found, but is almost exhausted. Maryland is expected to supply soda felspar in the future; the soda pegmatites contain 6% Na_2O and 4% K_2O. In Virginia and North Carolina, felspar has been subsidiary to mica mining hitherto. In Georgia the production of felspar has not yet been attempted.—H. H. S.

Plaster; Note on the transverse test applied to pottery ——. F. B. Allen. Trans. Amer. Ceram. Soc., 1914, **16**, 98—100.

The transverse, as an alternative to the tensile, test was carried out by suspending plaster bars on knife edges and breaking them by means of a load applied at the middle. The load consisted of a bucket into which water was poured until rupture occurred. The formula used is $S = \frac{3}{2} \cdot \frac{Pl}{bd^2}$, where S is the modulus of rupture in lb. per sq. inch, P the load, l the length in inches, and b and d, the width and depth respectively of the cross-section. The average of tests on good material was found to be 608. A good tensile standard is about 600 lb. per sq. inch. —H. H. S.

Potash-soda felspars; Use of mixed —— in porcelain. A. S. Watts. Trans. Amer. Ceram. Soc., 1914, **16**, 212—215.

The introduction of soda felspar into felspathic porcelain is found to cause warpage when equal parts of soda- and potash-spar are used, if the ware is not fired above cone 8 (1290° C.). Above this temperature, warpage increases with the content of soda-spar, until it constitutes 83% of the total felspar present; then warpage decreases up to 100% soda-spar, indicating that pure soda felspar would cause less warpage than any natural mixture of the two spars. Shrinkage increases with the content of soda spar, but only slightly after the ratio equals 1 : 1. If the firing temperature exceed cone 8, shrinkage increases up to the ratio 62 potash- : 38 soda-felspar, and with additional soda-spar decreases slightly. Translucency increases with the content of soda-spar, but above cone 8 decreases in all cases.—H. H. S.

Porcelain body; The influence of calcium and iron chlorides precipitated in a ——. B. S. Radcliffe. Trans. Amer. Ceram. Soc., 1194, **16**, 127—130.

As clays that naturally burn red have a high absorption, and as the colours are not always uniform, porcelain slips were mixed with solutions of iron and calcium chlorides, which were then precipitated by addition of ammonia and ammonium carbonate. Bodies high in iron were more plastic than those high in lime, and the dried tiles were stronger. All the bodies were completely vitrified at cone 9. Suitable uniform gray colours can be obtained by precipitating 0—2% Fe in a porcelain body, and uniform red colours by 4—6% Fe. The porosity in the latter case need not be more than 3—4%.—H. H. S.

Ferric oxide [as colouring agent in pottery]; A note on the reduction of ——. C. S. Kinnison. Trans. Amer. Ceram. Soc., 1914, **16**, 136—143.

Ferric oxide at atmospheric pressure cannot exist above 1350° C.; it dissociates into oxygen and magnetic oxide, which in presence of silica, as in clay, forms ferrous silicates dark brown to black in colour. This colour-change was taken as criterion of reduction of ferric oxide when added to the extent of 5% to various mixtures of kaolin, flint and felspar. The results show that the temperature of formation of ferrous silicate is qualified by the $Al_2O_3 : SiO_2$ ratio of the body mixture; the smaller the ratio (which varied from 1 : 2 to 1 : 9), the lower the temperature. Seger's statement that the lower the $Al_2O_3 : Fe_2O_3$ ratio, the lighter are the colours developed, is confirmed. Fluxes influence the colouring properties of iron oxide in opposite ways; at low temperatures where the amount of fused material is small, the colour is intensified by suspension of iron particles: but with more fused material present, iron is taken into solution and the colour then depends on composition and temperature. In acid clays reduction of Fe_2O_3 takes place at lower temperatures than in more aluminous bodies: 1320° as compared with 1390° C. When fluxes are present the dissociation temperature is 1210—1220° C.—H. H. S.

Soluble salts in clay; Influence of —— upon behaviour of slip and glaze. M. A. Coats. Trans. Amer. Ceram. Soc., 1914, **16**, 162—168.

A TERRA-COTTA clay containing 0·356% of soluble sulphates was used for the body, and amounts up to 5% $CaSO_4$, 5% NaCl, 4·5% $MgSO_4$, 5·0% $CaCl_2$, and 3·5% $FeSO_4$, were further added separately. The presence of soluble salts in the body caused peeling of slip or glaze, the amount present not being material. Application of the glaze to the "leather-hard" body did not eliminate the trouble. Fixation of the sulphates by addition of barium carbonate was an effective remedy.—H. H. S.

Terracotta bodies, slips, and glazes. G. D. Phillips. Trans. Amer. Ceram. Soc., 1914, **16**, 169—178.

In attempts to produce a satisfactory combination of body, slip and glaze to mature at cone 6—7 for architectural terracotta, the trials were pressed in plaster moulds, removed as soon as possible, and tooled to a finished surface. The body selected had the composition: Stoneware clay 79·5, grog (12—45 mesh) 20, barium carbonate 0·5%. The slip was made from the mixing: china clay 25, Tennessee ball clay 6, Cornwall stone 45, German ball clay 6, flint 20, sodium carbonate 1 part by weight. A bright white glaze was made from the formula: 0·16 K_2O, 0·40 CaO, 0·35 BaO, 0·09 ZnO, 0·41 Al_2O_3, 3·7 SiO_2; and a matt white from the formula: 0·16 K_2O, 0·44 CaO, 0·35 BaO, 0·05 ZnO, 0·37 Al_2O_3, 1·9 SiO_2. The ware was fired to cone 6 in a 50 hour burn, with slow cooling. —H. H. S.

Roofing tile slips and glazes. E. T. Montgomery and C. F. Tefft. Trans. Amer. Ceram. Soc., 1914, **16**, 144—150.

The composition of slips and glazes depends on whether the tile is to be burnt in one fire, at cone 02, or in two fires of which the second is at cone 010—07 (see Ohio Geol. Survey, Bull. 11, "Manuf. of Roofing Tiles"). The use of a dull glaze or one which is matt owing to immaturity is recommended instead of a slip. At cone 02, a glaze of this kind may be made from the formula: 0·6 PbO, 0·25 CaO, 0·15 K_2O, 0·35 Al_2O_3, 1·3 SiO_2, with the addition of the usual colouring agents. At cone 010—07, a dull glaze of the following composition may be used: 0·1 K_2O, 0·5 PbO, 0·25 CaO, 0·15 BaO, 0·15—0·3 Al_2O_3, 1·5—3·0 SiO_2; or a matt glaze of composition: 0·8PbO, 0·1 CaO, 0·1 K_2O, 0·21 Al_2O_3, 1·4 SiO_2.—H. H. S.

Underglaze colours; Production of —— by use of soluble metallic salts. R. M. Howe. Trans. Amer. Ceram. Soc., 1914, **16**, 487—496.

The salts used, viz., nitrates of cobalt, uranium and nickel, sulphates of iron and manganese, and chromium chloride, were deposited by evaporation from solution on bases such as aluminium hydroxide, kaolin, silica, bone ash and zinc aluminate, and calcined at cone 7. The colours were then ground and applied to biscuit ware with ball clay and glycerin, and fired to 600° C. in order to render them firm for dipping into glaze. Earthenware trials were fired to cone 07 in 6 hours, stoneware to cone 7 in 24 hours, and porcelain to cone 10 in 36 hours. Good results were obtained by this method of introducing very small quantities of colouring agents by means of their solutions. Cobalt on alumina yielded good colours at all temperatures; cobalt on zinc aluminate was good at the higher temperatures, but greenish at cone 07; cobalt on flint also behaved well. Uranium on alumina gave nice yellows under oxidising, and pretty grays and blacks under reducing, conditions; uranium on kaolin was not so easily influenced by the atmosphere. Iron on kaolin gave good yellows at cone 07, and browns at the higher cones; iron on bone ash was useless. Chrome-alumina pink was successful at cones 7 and 10, and a better pink was obtained from chrome on zinc aluminate; but the latter destroyed all green colours. Manganese on aluminium hydroxide gave exceptionally good pinks with low Mn content at the higher cones, but with increasing content of stain blistered badly.—H. H. S.

Chromium oxide as colouring agent; Effect of variation of RO elements upon —— in a matt glaze. R. H. Minton. Trans. Amer. Ceram. Soc., 1914, **16**, 248—263. (See also Pence, this J., 1914, 80.)

Experiments were made to determine the effect of CaO, BaO, MgO, and ZnO, separately and in combination, upon Cr_2O_3 in a matt glaze in which K_2O, Al_2O_3, and SiO_2 were kept constant at 0·2, 0·35, and 2·25 equivalents respectively, and Cr_2O_3 at 1·75%. The effect of the above bases on chromium colours is summarised as follows: CaO singly, fine green; CaO and ZnO together, pink to brown in increasing quantities; CaO and BaO, very dark green; CaO and MgO, brown; CaO and PbO, fine bright green; ZnO alone, light fawn; ZnO and BaO, brown; ZnO and MgO, pinkish brown; ZnO and PbO, brown and strong pink; BaO alone, yellow or apple green; BaO and MgO, gray; MgO alone, fawn, stronger than ZnO in effect. In fluxing power, CaO alone is superior to either BaO, MgO or ZnO alone; CaO and ZnO together are superior to any other dual combination; CaO and MgO together do not flux in any proportion (cone 4 down). The uncertain action of zinc in chromium glazes is due to atmospheric conditions in the kiln, the tendency of zinc being to form chromate; both yellow and green and their variations may be found on the same piece. The introduction of chromium as a prepared stain rather than as the raw oxide is recommended. The two following, containing zinc and chromium, and calcined at cone 5, are stable in glazes containing no zinc: (*a*) 1 part of ZnO, 1 of Cr_2O_3, 1 of flowers of sulphur, and 0·01 of Co_3O_4, produce a dark green; (*b*) 40 parts of Cr_2O_3, 20 of ZnO, 5 of Co_3O_4, 20 of SiO_2, and 15 of borax, produce a dark blue green.—H. H. S.

Cobalt-uranium colours [for pottery glazes]; Some ——. B. S. Radcliffe. Trans. Amer. Ceram. Soc., 1914, **16**, 209—211.

In addition to the four oxides, of copper, chromium, nickel and iron, which singly produce green colours, a blend of cobalt blue and uranium yellow is found to be green when fired as when physically mixed. The proportions recommended are 4 or 5 parts of uranium nitrate to one of cobalt nitrate.—H. H. S.

Porcelain glazes; Deformation temperatures of some ——. R. T. Stull and W. L. Howat. Trans. Amer. Ceram. Soc., 1914, **16**, 454—460.

Cones were made of glaze mixtures and their deformation temperatures were determined in a platinum resistance furnace. RO was kept constant in all glazes at $0{\cdot}3K_2O$, 0·7CaO; Al_2O_3 was varied between 0·4 and 0·85 equiv., and SiO_2 between 2·0—6·5. The difference between maximum and minimum deformation temperatures was 57° C.; the softest, deforming at 1220° C. (Seger cone 4 = 1212° C.) having the formula $RO,0{\cdot}6Al_2O_3,4{\cdot}0SiO_2$; and the two hardest, deforming at 1277° C. (approximately cone 7) the formulæ $RO,0{\cdot}85Al_2O_3,2SiO_2$, and $RO,0{\cdot}4Al_2O_3,6{\cdot}5SiO_2$. The glazes were also fired on bisque tiles at cone 9, and the best results found to be obtained from the formulæ, with deformation temperatures of the cones of the same composition: (*a*) $RO,0{\cdot}6Al_2O_3,4{\cdot}0SiO_2$ (1220° C.); (*b*) $RO,0{\cdot}55Al_2O_3,3{\cdot}5SiO_2$ (1227° C.); (*c*) $RO,0{\cdot}55Al_2O_3,4{\cdot}0SiO_2$ (1230° C.); (*d*) $RO,0{\cdot}6Al_2O_3,3{\cdot}5SiO_2$ (1222° C.). The difference between their deformation temperature and their best firing temperature is 80°—90° C., a difference of 4—4½ Seger cones. The best glazes in any group are found in close proximity to the group eutectic.—H. H. S.

Crystalline glaze; A type of —— at cone 3. C. C. Rand and H. G. Schurecht. Trans. Amer. Ceram. Soc., 1914, **16**, 342—346.

The glaze selected had the formula: $0{\cdot}3Na_2O,0{\cdot}65ZnO,0{\cdot}05CoO,0{\cdot}05Al_2O_3,0{\cdot}3B_2O_3,1{\cdot}8SiO_2,0{\cdot}2TiO_2$. Slight variations of Na_2O and ZnO did not appear to affect crystallisation or colour. Increase of TiO_2 caused crystals to become smaller and more numerous, and deteriorated the cobalt blue, owing perhaps to iron impurities in the rutile. Trials were drawn from the kiln as cooling progressed; crystallisation increased steadily from 1170° C. downwards, till at 1030° C. the glaze was a mass of crystals, suggesting crystallisation of an eutectic. A thick coating of glaze applied to the ware was found to give the best result.—H. H. S.

Coloured porcelain glazes at cone 10. E. T. Montgomery and I. A. Kruson. Trans. Amer. Ceram. Soc., 1914, **16**, 317—363.

The colourless glaze used as base varied in composition, the extremes being: (1) $0{\cdot}3K_2O,0{\cdot}7CaO,0{\cdot}4Al_2O_3,3{\cdot}8SiO_2$; and (4) $0{\cdot}25K_2O,0{\cdot}55CaO,0{\cdot}1Na_2O,0{\cdot}1ZnO,0{\cdot}3Al_2O_3,3{\cdot}0SiO_2,0{\cdot}2B_2O_3$. Borax, when used, was introduced raw in amounts up to 10% without difficulty. All glazes were raw, and applied to the dry "green" ware and fired in one burn to cone 10. The minimum and maximum amounts of the usual colouring oxides, employed singly, necessary to produce satisfactory colours were as follows, in equivalents: CoO 0·025—0·10, CuO 0·125—0·2 (volatilisation occurs), MnO_2 0·1—0·25, Cr_2O_3 (Zn absent) 0·015—0·15, Fe_2O_3 0·025—0·1, U_2O_3 (introduced as $Na_2U_2O_7,6H_2O$) 0·01—0·02, NiO 0·05—0·15. Some 21 recipes are given as batch weights for the production of commercially desirable colours, blacks, greens, browns and slate-colours. Experiments were also made on the production of less usual colours in a porcelain glaze by rare elements, fritted stains, and calcined colour bodies. Rutile in amounts from 5—10% gave light to deeper yellow. A solution of platinum chloride 0·5 part, cobalt nitrate 0·14, with glycerin 1·9 and dextrin 1·0, yielded black; and from 0·04—0·06 equiv. of U_2O_3 black was obtained under reducing conditions. Pinks were produced by chrome-tin, chrome-alumina and manganese-alumina stains, and by gold chloride solution. At these high temperatures tin oxide must not be used when chromium oxide greens are desired. A large variety of colours can be obtained at cone 10.—H. H. S.

Vitrification; The legal definition of ——. E. Orton, jun. Trans. Amer. Ceram. Soc., 1914, **16**, 497—511.

As clay products which are visibly glassy are practically certain to be overburned and worthless, and as all clay products whether much or little vitrified show some portions of glassy matrix under magnification, the author proposes a quantitative absorption test in order to ascertain "vitrification." The definition he suggests for a legal standard is as follows: "Where the word vitrified is used in a contract or agreement as an adjective in describing the properties of a clay product, without further definition in such contract, it shall mean that the product shall have attained in the firing process such a degree of structural density that its mean absorption of pure water will not exceed 3% of its own initial weight, when subjected to absorption tests of 48 hours' complete immersion in cold water or 3 hours' immersion in boiling water. Not less than three tests shall be made in determining the mean absorption, and no single test may exceed the mean by more than 0·5%. Neither the possession of the visual properties or appearance of a glass, nor any definite degree of physical strength, hardness, colour, or specific gravity, shall be implied as an attribute of vitrification." —H. H. S.

Producer gas-fired continuous [*pottery*] *kiln; Present status of* —— *in America.* R. H. McElroy and G. R. Mumma. Trans. Amer. Ceram. Soc., 1914, **16**, 585—605.

An 18-chamber kiln at Toronto is described as representing the most recent advance in efficiency and economy. Three 6 ft. water-sealed producers are fed with Yohoghany coal, three-quarters lump, together with slack and nuts, at a cost of $4 a ton delivered. The temperature of the gas is 850°—900° F. (about 450°—480° C.) in the necks of the producers. The steam pressure on the producer fuel bed is 60 lb. Stock bricks are made from a gray-burning calcareous glacial drift and a red-burning sandy weathered plain deposit. The chamber holds 58,000 bricks, weighing, after burning, 5½ lb. each, their size before fire being 9″×4″ and after, 8¾″×3⅞″. The fuel consumption is 285 lb. per 1000 bricks, and the time of burning 25¾ hours. The draught one chamber ahead of the fire is 0·5—0 in.; 3 chambers ahead, 2·0—1·5 in. A kiln is operated by two men on a shift.—H. H. S.

[*Pyrometers.*] *The Veritas firing rings.* A. V. Bleininger and G. H. Brown. Trans. Amer. Ceram. Soc., 1914, **16**, 222—231.

The principle involved in the use of these rings, invented by M. Solon, is the same as in the pyrometer devised by Josiah Wedgwood: that of shrinkage in fire. A clay body similar in composition to white ware (roughly, clay 52, flint 33, felspar 15%), is formed into rings 2·5 inches in diameter with a hole 0·85 inch diam. Progress of firing is followed by withdrawal of rings from various parts of the kiln. The rings share the properties and defects of Seger cones, but are more useful in the early stages of the fire as they swell up before dehydration, whereas a cone shows nothing until incipient softening by fusion occurs. Rings of a former batch should be preserved in order to check the behaviour of the next batch. —H. H. S.

IX.—BUILDING MATERIALS.

Lime mortars; Effect of consistency and amount of sand on the properties of ——. W. E. Emley. Trans. Amer. Ceram. Soc., 1914, **16**, 151—161.

To measure consistency, three different instruments were used: (1) Chapman's (Proc. Amer. Soc. Testing Materials, 1913); (2) the plunger instrument described in Trans. Natl. Lime Manuf. Assoc., 1911; (3) the Clark viscosimeter (Trans. Amer. Ceram. Soc., 1913). Chapman's instrument gave good results, covering the whole field and being sensitive to small changes of composition. Cylindrical plungers are sensitive and may be used for most of the mortars in practice. The Clark viscosimeter is acutely sensitive for lime paste, but useless for mortars. The strength of a mortar is influenced more by its consistency than by its composition; sand settles out when the paste becomes too thin. The mortars were finally moulded into two-inch cubes and after 60 days were measured for shrinkage and their crushing strength determined. The following three, out of seven, had crushing strengths of over 200 lb. per sq. inch: (*a*) lime 20, water 20, sand 60; (*b*) lime 25, water 20, sand 55; (*c*) lime 20, water 15, sand 65% by weight.—H. H. S.

Lime mortar; Method of indicating the rate of set of ——. W. E. Emley. Trans. Amer. Ceram. Soc., 1914, **16**, 117—119.

The final hardening of mortar, due to the reaction between lime and atmospheric carbon dioxide, begins at the surface and proceeds to the interior at a rate dependent on the porosity of the mortar and other factors influencing the circulation of air within the mass. The proportion of water originally present in the mortar is also of importance, as a certain amount is necessary to promote chemical action, and excess requires to be evaporated. To ascertain the influence of the penetration of carbon dioxide on setting, bars of mortar were made up with an aqueous 0·1% solution of Wool Blue R, which is rendered colourless in presence of lime and restored to dark blue by carbon dioxide. The line of demarcation was sufficiently distinct for the extent of carbonate formation to be measured when the bar was sawn through. With bars 1 sq. inch in section, exposed to the action of air in a room, the penetration of the carbon dioxide was complete in about four months.—H. H. S.

Mortars; The use of fine earth in ——. H. K. Benson and J. S. Herrick. J. Ind. Eng. Chem., 1914, **6**, 796—797.

Samples of fine earth of various kinds were mixed with lime or with Portland cement, and with water, kept in moist air for 24 hours, formed into blocks under a hydraulic pressure of 2000 lb. per sq. in., air-dried for 24 hours, and treated with live steam at 80 lb. pressure for 8—16 hours. With suitable proportions of the binding agent (lime or cement) it was possible to obtain from all the samples of earth blocks having a crushing strength of about 3000 lb. per sq. in. and upwards. Some of the blocks had crushing strengths ranging from 6200 to 9750 lb. per sq. in. In presence of soluble organic matter (straw infusion or tannin), strong blocks could not be obtained from earths of sandy texture, but loamy earths gave blocks having a crushing strength of over 3000 lb. per sq. in.—A. S.

Portland cement; Hydration of ——. A. A. Klein and A. J. Phillips. Trans. Amer. Ceram. Soc., 1914, **16,** 313—341.

THE binary compounds known to be present in Portland cement, viz., three aluminates: $CaO.Al_2O_3$, $5CaO.3Al_2O_3$, and $3CaO,Al_2O_3$; and four silicates: $CaO.SiO_2$, $\gamma 2CaO.SiO_2$, $\beta 2CaO,SiO_2$, and $3CaO,SiO_2$, were prepared in as pure and homogeneous a condition as possible. Lime was also burned at different temperatures. Tests were also made on high-silica, low-silica, and high-iron cements. Samples were hydrated on microscope slides with excess of water under conditions precluding evaporation and action of carbon dioxide. They were also hydrated in a cylinder with superheated steam at atmospheric pressure (Bied's method. Proc. Int. Assoc. Testing Materials, **2,** [9], 8), and in an autoclave with steam at various temperatures and pressures. Finally, they were moulded with limited quantities of water approximating to those used to obtain normal consistence. In addition to water, lime-water and calcium sulphate solution were employed as hydrating agents. Examination of changes produced was conducted by petrographic methods. No evidence was obtained of abnormal hydration reactions in the autoclave, except in the changing of optical properties of gypsum and hydrated $3CaO.Al_2O_3$, due to dehydration, which was overcome by use of more water in the autoclave. At very high steam pressures (600 lb. for 2 hours), there were observed large growths of calcium hydroxide crystals; but with lower pressures, the conditions of the autoclave approximated to 28 days normal hardening. The process of hydration is considered to be as follows. Amorphous hydrated $3CaO.Al_2O_3$ is formed, with or without amorphous alumina, and later crystallises. At the same time sulphoaluminate crystals are formed, and lime, if low burned or finely ground, is hydrated. These reactions begin within a few hours after the cement is gauged. The next compound to react is $3CaO.SiO_2$: its hydration may begin within 24 hours, and is generally complete within seven days. Between a week and a month, the amorphous aluminate commences to crystallise, and hydration of $\beta 2CaO.SiO_2$ begins. Although the last-named compound is the chief constituent of American Portland cements it is the slowest to react. The early strength of cements (after 24 hours) is due to hydration of lime and aluminates. Increase in strength between one and seven days depends upon hydration of $3CaO.SiO_2$, though further hydration of aluminates may contribute. Increase between 7 and 28 days is due to hydration of $\beta 2CaO.SiO_2$, but is counteracted by hydration of high-burnt free lime and crystallisation of aluminates, which may cause a decrease in strength during this period. Finally, iron compounds in cement resist hydration and occur as a rust-like material. The disintegrating action attributed to crystallisation of $3CaO,Al_2O_3,3CaSO_4,xH_2O$ is said to have been greatly exaggerated, as such crystals are extremely small, and they begin to form before the cement mass has assumed any great rigidity.—H. H. S.

White Portland cement; Some properties of ——. P. H. Bates. Trans. Amer. Ceram. Soc., 1914, **16,** 551—570.

WHITE cement sets more quickly than gray cement, owing to the absence of iron oxide, which, contrary to the old idea, cannot be compensated by higher alumina content. The difficulty is enhanced by the finer grinding required to obtain a product of good colour. White Portland cement may be readily produced in a rotary kiln at a temperature but little above that used for ordinary cement, if the silica content of the latter be raised, and the alumina decreased, while the lime is kept the same. A lower alumina content is necessary because, while it is not shown that high alumina makes quick-setting cement, the temperature of softening is materially reduced with such increase, and the clinker "rings up" the kiln. High silica necessarily follows, as high lime would cause difficulty in reaching a temperature high enough to produce a sound cement (see this J., 1914, 81). The calcium sulphate content which produced the best time of set, viz., 2%, is not the same as that which produced the best strength, 4%; strength therefore is accompanied by quicker setting. Petrographic analyses of the clinkers showed that in all cases βcalcium orthosilicate was the most important constituent, followed by $3CaO,SiO_2$. The only aluminate present was $3CaO,Al_2O_3$. The composition of the best clinker was: SiO_2 25·94, Al_2O_3 6·55, Fe_2O_3 0·44, CaO 65·50, MgO 1·35, Na_2O 0·07, K_2O 0·12, loss on ignition 0·36%. A mixture of flint, alumina and limestone, gives better results than one of clay and limestone, and this in turn is better than one of felspar and limestone.—H. H. S.

Portland cement; Note on a rare anomaly in the setting properties of ——. F. Ferrari. Annali Chim. Appl., 1914, **2,** 68—74.

TWO samples of Portland cement set almost instantaneously, with considerable evolution of heat, about 1 hour after gauging. The clinker from which the cement was made was found to consist of two distinct products—one, of a greenish yellow colour, not completely sintered, free from puzzuolanic substances but rich in free lime and containing free calcium aluminates; the other, of a brown colour, nearly fused, rich in puzzuolanic substances, and containing no free lime. These two products when ground separately both gave slow-setting cements. It is considered that when the cement from the two products together was gauged, the free lime dissolved rapidly and prevented the hydration of the calcium aluminates. The puzzuolanic substances present in the nearly fused product were in sufficient quantity to fix the whole of the free lime, and when this had taken place hydration of the aluminates became possible and these exhibited their known quick-setting properties. The abnormal cement could be made slow-setting by addition of a small quantity (1%) of lime.—A. S.

Cement: Influence of organic admixtures on the setting of ——. H. K. Benson, C. A. Newhall, and B. Tremper. J. Ind. Eng. Chem., 1914, **6,** 795—796.

SAMPLES of Portland cement, with and without addition of gypsum, were mixed with various organic compounds typical of the classes of substances that might be expected to be present in soil or sand deposits, and the effect on the setting properties of the cement observed. The results are given chiefly in curve-diagrams. Certain substances, *e.g.*, tannin, straw infusion, oxalic acid, quinoline, and soap, which produced a precipitate with the cement and also with calcium chloride solution, greatly accelerated the initial set and greatly retarded the final set. Other organic substances, however, also exerted a retarding effect on the final set and the action cannot be attributed to any particular class of compounds. No evidence of catalytic action was obtained.—A. S.

Refractories; Relative thermal conductivities of silica and clay ——. G. H. Brown. Trans. Amer. Ceram. Soc., 1914, **16,** 382—385.

THE composition of the three sample bricks tested was:—Silica brick: SiO_2 95·48, Al_2O_3 1·92, Fe_2O_3 1·42, %; quartzite brick: SiO_2 83·36, Al_2O_3 11·79, Fe_2O_3 1·69, %; clay brick: SiO_2 63·24, Al_2O_3 32·97, Fe_2O_3 1·33, %. Readings were taken up to 1300° C. The relative thermal conductivities of the bodies, silica, quartzite, and clay, were found to be as 1017 : 986 : 933, silica brick thus having a conductivity 9·0%, and quartzite 5·7%, greater than that of clay.—H. H. S.

Building brick; Absorption of water by ——. H. W. Mahr. J. Ind. Eng. Chem., 1914, 6, 800—803.

Bricks of various characters were subjected to absorption tests (48 hours total immersion and the boiling test recently proposed in the Proc. Amer. Soc. for Testing Materials, 1913, 13, 287) in a 2 % solution of potassium ferrocyanide, then split by means of a chisel, dried, soaked in ferric chloride solution, dried and washed. The degree and character of the penetration of the solution was clearly revealed by the blue precipitate formed. A series of photographs is reproduced, and it is concluded that whilst in the boiling test water is forced into cores not penetrated in the 48 hours total immersion test, the latter gives results which are more concordant and more in conformity with the behaviour of the brick under natural conditions.—A. S.

Magnesite; The effect of steam upon magnesite brick or calcined ——. R. H. Youngman. Met. and Chem. Eng., 1914, 12, 620.

Attention is drawn to the hydration of calcined magnesite (pure and impure) by steam, more particularly in connection with the practice of laying magnesite brick upon moist, refractory material, as in the preparation of furnace bottoms.—W. E. F. P.

Zinc in treated wood; New method for the determination of ——. M. H. Bedford and R. Pfanstiel. J. Ind. Eng. Chem., 1914, 6, 811.

To destroy the organic matter, 3 grms. of the finely-divided wood are mixed with 35 grms. of sodium peroxide and burnt in an iron bomb. Water is afterwards introduced through an opening in the side of the bomb, closed by a screw plug, and the zinc is determined as described by Bateman (this J., 1914, 138). The method gave satisfactory results with red oak sawdust impregnated with zinc chloride.—A. S.

Note on the transverse test applied to pottery plaster. Allen. *See* VIII.

Patents.

[*Asphaltic*] *Paving material.* E. J. Lovegrove and N. G. Crompton, London. Eng. Pats. 5989 and 7539, March 9 and 25, 1914.

A mixture of finely divided clinker or the like (preferably from a dust destructor) with 10—20 % of its weight of bituminous material, or a mixture of gritty material, such as sand or small stone particles, with 10—20 % of bituminous material and a filling of clinker or ash in impalpable powder. The hot clinker is preferably pulverised immediately after withdrawal from the furnace and further drying or heating effected by the destructor gases. The ingredients may be mixed at 275°—375° F. (135°—191° C.) and the mixture laid at 250 —350° F. (121°—177° C.).—F. Sodn.

Wood preservative. J. C. Fitzsimmons, San Francisco, Cal. U.S. Pat. 1,111,302, Sept. 22, 1914; date of appl., June 23, 1913.

A mixture of heavy mineral oil and cresol, each preferably of sp. gr. about 0·98. For example, a mixture of oil of asphaltum base, of 14° B. (sp. gr. 0·98), with 10 % of cresol and having a b.pt. of about 200° C.—F. Sodn.

Concrete structures; Process of hardening ——. S. W. Flesheim, Assignor to Master Builders Co., Cleveland, Ohio. U.S. Pat. 1,113,112, Oct. 6, 1914. Date of appl., Aug. 11, 1913.

See Eng. Pat. 24,420 of 1913; this J., 1914, 422.—T. F. B.

Producing indurated articles. U.S. Pat. 1,111,286. *See* XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Bog iron ores; Treatment of —— by Kjeldahl's method for the destruction of organic matter. L. Brandt. Stahl u. Eisen, 1914, 34, 630—631.

To complete the oxidation of organic matter after 1 grm. of the ore has been heated with 20 c.c. of strong sulphuric acid, 0·35—0·45 grm. of hydrated manganese dioxide is added.—O. E. M.

Iron; Solubility of hydrogen and of nitrogen in ——. E. Jurisch. Stahl und Eisen, 1914, 34, 252.

Above 400° C. equilibrium between iron and hydrogen is quickly established. In experiments at atmospheric pressure with 100 grms. of iron wire, containing 0·04 % C, the results were :—

Temp., °C.	Hydrogen absorbed, mgrms.	Temp., C.	Hydrogen absorbed, mgrms.	Temp., C.	Hydrogen absorbed, mgrms.
416	0·035	852	0·264	1033	0·526
518	0·075	878	0·315	1136	0·632
620	0·118	899	0·390	1250	0·776
724	0·178	904	0·383	1350	0·949
775	0·210	930	0·431	1450	1·079
827	0·242	981	0·480		

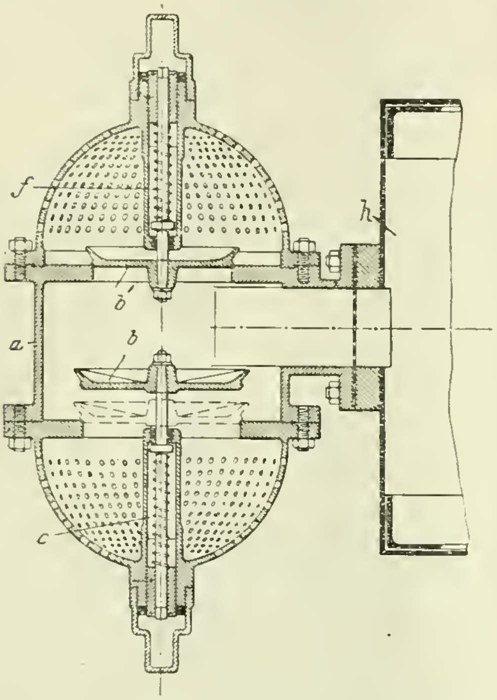
The steep ascent in the curve between 850° and 900° C. is attributed to the allotropic change in the metal. After slow cooling only 0·01 mgrm. of hydrogen remained absorbed. Between 600° and 930° C. an appreciable formation of methane occurred, especially with specimens containing higher amounts of carbon. At pressures ranging from 750 to 23 mm. and at 620° (α-iron), 775° (change of α-iron to β-iron) and 930° C. (γ-iron), the amounts of hydrogen absorbed were proportional to the square root of the pressure. The amounts of nitrogen at 760 mm. pressure, absorbed by 100 grms. of reduced iron in powder were :—878°, 1·58; 930°, 21·65; 981°, 21·03; 1033°, 20·22; 1084°, 19·73; and 1136° C., 18·85 mgrms. Absorption commenced at about 850° C.; and, after slow cooling, in two experiments quantities of 2·63 c.c. and 3·67 c.c. remained absorbed. The amount of nitrogen absorbed was proportional to the square root of the pressure.—J. B.

Carbon in steel; Determination of —— by the direct combustion method. W. Brady. J. Ind. Eng. Chem., 1914, 6, 843—846.

A description of the process and apparatus in use in the laboratory of the Illinois Steel Co. (compare Cain, this J., 1914, 696). Fine drillings of the steel are sifted and the portion passing a 10-mesh sieve in the case of medium- or high-carbon steel, or a 20-mesh sieve in the case of low-carbon steel, and remaining on a 40-mesh sieve, is used as sample. Combustion is effected in a nickel or platinum boat lined with alundum and placed in a quartz tube, 24 ins. long by ¾ in. diameter. Platinised asbestos mixed with broken pieces of quartz tubing is used as a catalyser in the hot part of the combustion tube and the space from the catalyser to the end of the tube is filled with pieces of quartz: the forward part of the tube is left empty. The furnace, heated by gas, or electrically, is kept at 960°—1000° C. The carbon dioxide is absorbed in excess of standard barium hydroxide solution in an Erlenmeyer flask and a nine-bulb tube, and the excess is titrated with hydrochloric acid in presence of phenolphthalein, without filtering. A bubble tube containing granulated zinc is interposed between the combustion tube and the absorption apparatus to retain sulphuric acid, most of which, however, condenses in the exit end of the combustion tube from which it is removed, after about 50 determinations, by moving this end into the furnace and drawing a slow current of oxygen through. —A. S.

Cupola furnaces; Explosions in —— and a safety-device for avoiding them. F. Osswald. Stahl u. Eisen, 1914, 34, 349—352.

EXPLOSIONS in cupola furnaces are due to the passage of carbon monoxide from the furnace back into the blast conduits when the blast is interrupted, the gaseous mixture igniting when the blast is re-started. A device for automatically preventing the accumulation of gas in the blast passages when the blast is interrupted, comprises a valve-box, *a*, attached to the blast chamber, *h*, of the furnace, and fitted with two lift-valves, *b*, *b′*. The upper valve, *b′*, is loaded by the spring, *f*, and opens only when the pressure exceeds the maximum blast pressure used. When the blast is interrupted the lower valve, *b*, is forced upwards by the spring, *c*, and an up-draught is maintained through the furnace. On re-starting the blast, the air or gas passes freely from the blast-chamber, *h*, through valve, *b*, to the atmosphere until the pressure has increased sufficiently to close the valve.—A. T. L.



Vanadium; Determination of —— in ferro-vanadium and steel. O. Wilms and P. Fischbach. Stahl u. Eisen, 1914, 34, 417—418. (See also König, this J., 1914, 315.)

CAMPAGNE's method, in which a solution of the metal in nitric acid is evaporated with hydrochloric acid, and the oxychloride titrated with potassium permanganate at 80°—85° C. in the presence of phosphoric acid, gives low results owing to the volatility of the oxychloride. If sulphuric acid be added, the solution evaporated until sulphuric acid fumes escape, cooled and diluted, before adding hydrochloric acid, then during the subsequent evaporation, the non-volatile oxysulphate is formed: $V_2O_2Cl_4+2H_2SO_4=V_2O_2(SO_4)_2+4HCl$.—A. T. L.

Platinum ore in S. Nevada. F. A. Hale, jun. Eng. and Min. J., 1914, 98, 641—642.

ORE recently discovered at the Boss Mine, 10 miles W. of Goodsprings, contained Pt 0·5—1, and Au 0·75—1·5, oz. per ton, with some silver and small amounts of base metals. The deposit occurs in limestone, in a crushed fault-zone which also traverses a batholithic intrusion of acid porphyry; the ore is oxidised, the platinum and gold being present in metallic form but "alloyed."
—W. E. F. P.

Copper refining; Cathode potential in ——. K. S. Guiterman. Eng. and Min. J., 1914, 98, 601—603. (See also this J., 1914, 923.)

IN laboratory experiments, results confirming those of the previous investigation were obtained as regards current efficiency, the slight variations in which were accompanied by concurrent changes in cathode potential. The latter was slightly increased by the presence of glue; practically unaffected by salt, arsenic, ferrous iron or nickel; temporarily decreased by ferric iron, although gradually restored as the iron became reduced to the ferrous state; but was never lower than that necessary for the deposition of copper. The equilibrium potential of hydrogen was only exceeded under extreme conditions of high current density and low temperature of electrolyte.—W. E. F. P.

Copper; Commercial classification of refined ——. L. Addicks. Amer. Inst. of Metals, Chicago, Sept., 1914. Met. and Chem. Eng., 1914, 12, 641—643.

THE sources and methods of production and purification of copper are considered in relation to the uses of the metal. Furnace refining is restricted to relatively pure crude copper; otherwise a low-grade refined metal is obtained. Electrolytic cathodes generally contain about 0·05% of impurity, of which 0·02 is metallic and the remainder probably hydrogen; but, in the absence of special precautions, the metal is contaminated on melting. The conductivity of perfectly pure, soft copper is probably about 103% of the Matthiessen standard in common use; a representative sample of electrolytic copper of 100% conductivity (annealed) contained Cu 99·93, O 0·04, Ni 0·004, Fe 0·0035, S 0·003, Sb 0·003, As 0·002, Pb 0·002, Al 0·001, Ag 0·001, Se 0·0005, Te 0·0005, Au 0·00001%, and P and Bi traces. Only high-conductivity Lake, and electrolytic, coppers are used for electrical purposes; the former (from surface ores) is indistinguishable from the latter, the conductivity of each being 99—101%; electrolytically-refined, arsenical Lake copper (from increasing mine depths) is also classed as high-conductivity Lake. For brass making a content of not less than 99·88% Cu is usually specified. Casting copper is of indefinite composition and not amenable to specification at the present time, being best purchased on the basis of known brands.
—W. E. F. P.

Converter gases; Cottrell plant for —— at Garfield, Utah. W. H. Howard. Bull. Amer. Inst. Min. Eng., Aug., 1914. Eng. and Min. J., 1914, 98, 653—654.

THE gases (from which lead fume, etc., is to be recovered by electrostatic treatment), are cooled, passed through a steel flue, 1000 ft. long and 210 sq. ft. in cross-section, in which part of the suspended matter is precipitated, and then delivered to the electrical precipitator. This has a total capacity of 250,000 cub. ft. of gas per min., and consists of seven units, each containing 360 vertical tube-electrodes, 10 ft. long and 5 in. in diameter, within each of which is a central No. 14 steel wire electrode; a regular flow is maintained through the tubes (at a velocity of 12 cub. ft. per sec. for full capacity), the gases being delivered to the lower, and conducted from the upper, chambers of each unit through three 36 in. pipes. The electrical equipment for each unit consists of a 30-h.p., 250-volt, direct-current motor, connected direct to a 20-kilowatt, 4-pole, 60-cycle, 220-volt, single-phase, alternating-current generator; the current (220 volts) is stepped up to 20,000—30,000 volts by means of a 20-kilowatt transformer, and rectified before being passed to the precipitator. The present tube and single wire electrodes were adopted (in place of the original plate and pubescent electrodes) as the result of experiments made with the Garfield gases in 1913, when 95—100% of the non-gaseous constituents were removed from the gases by maintaining the precipitator below 100° C., and the possibility of fractional precipitation of these constituents was demonstrated.
—W. E. F. P.

Tin resources of Australia, South Africa and Nigeria. Bull. Imp. Inst., 1914, 12, 442—458.

INFORMATION is given as to the localities in the above countries where tin occurs, with descriptions of the deposits and methods of working and statistics of production.—R. G. P.

Plating of non-metallic objects. E. Werner. Elektrochem. Zeits., 1913, **20**, 57—59.

Glass, stone, porcelain, etc., are given two or three coats of slow-drying copal varnish, dusted with copper or graphite powder before the last coat is dry, stoved for 24 hours, brush-polished, and plated in a slightly acid copper sulphate bath. Leather, rubber, and similar materials are washed with weak caustic soda, and soaked in hot paraffin wax solution before being coated. If the object cannot be covered with graphite, it is coated with gutta-percha solution, then with shellac in spirit, dipped in a silver solution, exposed to hydrogen sulphide, and copper plated. Animal and vegetable objects are soaked in ammonia, dipped in caustic alkali and in a weak acid bath, and washed, before treatment with silver solution. —O. E. M.

Nickel coatings; Black ——. E. Werner. Elektrochem. Zeits., 1913, **20**, 25—26.

The bath consists, for example, of: H_2O 100 litres, $(NH_4)_2SO_4,NiSO_4,6H_2O$ 8505 grms., $CuCO_3,Cu(OH)_2$ 1417, KCNS 2125, and H_3AsO_3 1417 grms. Among the conditions to be observed are: maximum density of bath, which must be neutral; large, old, anodes; potential difference not exceeding 1 volt; regular working; thin plating, as shown by attainment of a deep black, to avoid scaling. Alternative methods and details are given. —O. E. M.

Metals; Action of —— on water. W. P. Jorissen. Comptes rend., Inter. Pharm. Congress, 1913. Engineering, Oct. 23, 1914, 512.

The order of the metals when arranged according to their potential (referred to the hydrogen electrode) in normal solutions of their salts, is: Mg, Al, Mn, Zn, Cd, Fe, Co, Ni, Sn, Pb, H, Cu, Bi, Sb, Hg, Ag, Pt, Au; those preceding hydrogen being positive, and those following it being negative. The position of aluminium refers to the amalgamated metal; the position of the ordinary form is uncertain owing to its superficial coating of oxide. Aluminium keeps well in dry air, but oxidises superficially in moist air. Distilled water has little action upon it, but ordinary water may pit the surface; sea-water corrodes it strongly. Amalgamated aluminium decomposes dilute sulphuric acid, a contrast to amalgamated zinc. Zinc remains bright in distilled water free from gases, but in the presence of oxygen some hydroxide is formed which is sparingly soluble; rain-water dissolves it. Nickel is hardly attacked by air, moisture, sea-water and dilute hydrochloric and sulphuric acids. Pure tin is not attacked by water and dilute sulphuric acid so long as air is absent, but sea-water corrodes it in presence of air. The chloride and sulphate of lead being much more soluble than the carbonate, the presence of chlorides and sulphates in water increases the danger of lead poisoning. The action of a potable water on lead and zinc cannot be predicted from the composition of the water.—J. H. J.

Scheelite concentrates; Determination of phosphorus in ——. E. W. Hagmaier. Met. and Chem. Eng., 1914, **12**, 620. (See also this J., 1914, 923.)

One grm. is heated with hydrochloric acid and potassium chlorate, or with *aqua regia*, and evaporated to dryness, the residue treated with dilute hydrochloric acid (1 : 2), 15—20 c.c. of cinchonine solution and some paper pulp added, the mixture allowed to stand for ½ hour, filtered, and the residue washed with dilute hydrochloric acid containing cinchonine. The filtrate is treated with 10 c.c. of cerium chloride solution (1 grm. $CeCl_3$, 25 c.c. HCl and 250 c.c. H_2O) neutralised with ammonia, boiled for 5—10 mins. and filtered. The precipitate is dissolved in hot, dilute nitric acid (1 : 1), and the phosphoric acid precipitated with molybdate, as usual. With synthetic mixtures containing WO_3 65—70, Fe_2O_3 4—5, and P (a) 0·1, (b) 0·15, (c) 0·2, (d) 0·3%, the maximum and minimum results obtained for phosphorus were (a) 0·096 and 0·083, (b) 0·152 and 0·144, (c) 0·203 and 0·193, (d) 0·303 and 0·293%.—W. E. F. P

Radio-active minerals from W. Australia. Bull. 48, 1913, Geol. Surv. W. Australia; Bull. Imp. Inst., 1914, **12**, 501.

Hydrated silicates of uranium, thorium, and lead described under the names of mackintoshite, thorogummite, and pilbarite occur as constituents of the "main tantalite lode" at Wodgina.—R. G. P.

Pitchblende in Bengal. R. C. Burton. Rec. Geol. Surv. India, 1914, **44**, Pt. 1. Bull. Imp. Inst., 1914, **12**, 501—502.

Pitchblende occurs as rounded nodules in the pegmatite which is intrusive in mica schists at the mica mines at Singar, Gaya district Bengal. Triplite is so persistently associated with pitchblende and uranium ochre that it is taken as an indication of their presence. As yet not much pitchblende has been obtained, but one pit has yielded 4 cwts.; one nodule weighing 36 lb. has been obtained.—R. G. P.

Monazite. E. S. Simpson. Misc. Repts., Bull. 48, 1913. Geol. Surv. W. Australia. Bull. Imp. Inst., 1914, **12**, 500.

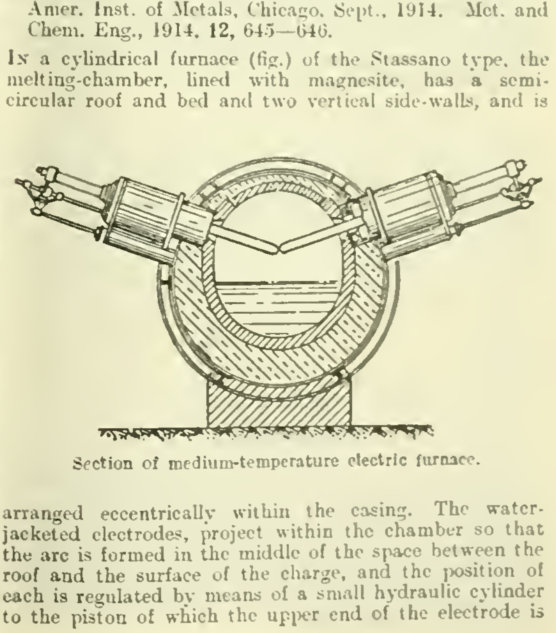
Monazite occurs associated with cassiterite and columbite in alluvial deposits at Cooglegong and Moolyella. The Moolyella material was obtained by re-sluicing low-grade tin gravels, yielding high-grade tin ore and a product consisting of 26·2% monazite, 26·3% cassiterite, 46·5% columbite and 1% garnet. Picked monazite from Cooglegong contained 3·8% and from Moolyella 5·03% ThO_2.—R. G. P.

Core-sand; Choice and treatment of ——. K. Irresberger. Stahl u. Eisen, 1914, **34**, 915—918.

The value of oil and flour as binders for core-sand is described, the sand in these cases being preferably free from lime, and also, with oil, from alumina. The sand grains should be of uniform size. To obtain the best results, test-cores should be prepared from different sands, and using different oils and drying temperatures. Representative samples in each case are withdrawn from the drying oven at measured intervals and the tensile strengths determined.—T. St.

Electric furnace for medium temperature. E. M. Schmelz. Amer. Inst. of Metals, Chicago, Sept., 1914. Met. and Chem. Eng., 1914, **12**, 645—646.

In a cylindrical furnace (fig.) of the Stassano type, the melting-chamber, lined with magnesite, has a semi-circular roof and bed and two vertical side-walls, and is arranged eccentrically within the casing. The water-jacketed electrodes, project within the chamber so that the arc is formed in the middle of the space between the roof and the surface of the charge, and the position of each is regulated by means of a small hydraulic cylinder to the piston of which the upper end of the electrode is



Section of medium-temperature electric furnace.

fixed. The charge is introduced at either or both ends of the furnace, the doors and also the electrode-holders and stuffing-boxes being gas-tight. The power factor of the furnace is over 90% ; no special transformers or starters are required ; and the furnace can be operated with direct or alternating current (single or 3-phase). In an experimental (120 kilowatt) furnace of this type, 1000 lb. of red copper were melted in less than 2 hrs., the power consumption being 240 kilowatt-hours per ton (2000 lb.) of metal.—W. E. F. P.

Gaseous metallic compounds. H. v. Wartenberg. Z. Elektrochem, 1914, **20**, 443—449.

A CONSIDERATION of Nernst's heat theorem and Trouton's rule showed that gaseous alloys are in general stable only at low temperatures and pressures. A determination of its heat of formation showed that $MgZn_2$ exists at 600° C., and vapour density determinations that it is dissociated at 1300° C. The vapour tensions of sodium and of Na_3Hg were measured at 444° C., and the stability of Na_3Hg at 380° and 444° C. demonstrated by distillation.—O. E. M.

Zinc output of the world. Engineering, Oct. 23, 1914. [T.R.]

THE production of zinc in Europe in 1913 amounted to 720,000 tons. The United States produced 346,670 tons, of which 51,300 tons was available for export. The only other sources of supply are Australia and Japan, whose combined output in 1913 was 11,300 tons. As regards the distribution of the European output, Germany in 1913 produced 289,870 tons, Belgium 217,920 tons, Great Britain 65,190 tons, France about 60,000 tons, and Spain 78,280 tons. The French smelters are outside the war area. A deficiency in the world's output of over 400,000 tons during the next 12 months is therefore probable. In 1913 Great Britain imported 64,670 tons of zinc ore and 145,000 tons of crude zinc ; 64,179 tons of the crude came from Germany.

Mercury and the war. Engineering, November 6, 1914, 570. [T.R.]

TRADING interests in mercury are attracting attention on account of its very extensive use in the preparation of fulminate for explosives, the present and probable future consumption of which must have an important bearing on the market for the metal, the withdrawal of available supplies, and the future demand.

The world's production is increasing ; the average for the last decade has been 3728 tons. The output during recent years has been as follows, in tons :—

1913.	1911.	1909.	1907	1905.
4171	3419	3233	3307	3336

The world's supply is obtained from only six countries, the main source being Spain ; the Almaden mines of that country produce nearly a third of the entire quantity. Recent outputs have been as follows, in tons :—

——	1913.	1911.	1909.
Spain	1490	1055	1000
United States	688	742	717
Italy	888	815	700
Austria	855	685	609

Ten years ago the United States' output of mercury was the largest in the world, exceeding 1000 tons for several successive years, but since then it has been declining ; the main American supply is obtained in California, and mostly from one mine. Great Britain's trade in mercury is peculiar, in so far as none is produced in the country ; it is purchased and distributed, and, in effect, controls the world's markets in the metal. The following schedule shows the imports, exports, and British consumption, in flasks, during recent years :—

——	Imports.	Exports.	Consumption.
1913	45,348	26,815	18,533
1912	47,262	32,240	15,022
1911	46,547	31,438	15,109
1910	44,595	24,748	19,847
1909	43,163	22,051	21,112
1908	43,605	22,348	21,257

Each flask contains 75 lb. In Austria the mercury deposits occur in Idria, Western Carniola, and in Italy, at Monte Amiata, Tuscany. The Mexican and Russian outputs are on a very limited scale ; four years ago the Russian output was only 4 tons. The price of mercury has risen enormously since the war commenced ; the Austrian supply, controlled by the Government, is definitely cut off from the world's markets, and the Italian supply is uncertain. The Spanish supply is controlled mainly in London, and very little may be obtainable for export. American supplies can scarcely be obtainable for export to Europe, as the consumption appears to have overtaken the production in the States. In fact, we have been exporting mercury to the United States in small quantities for some years—during 1913, 154,500 lb., to the value of £14,960.

Mercury imported was worth £7 9s. 3d. per flask last year, compared with £8 12s. 3d. during 1911. The war has had a marked effect on our mercury imports, as shown by the following figures :—

Imports for August.

1914.	1913.	1912.
1792 lb.	67,196 lb.	101,779 lb.
24 flasks	896 flasks	1357 flasks

Imports for September.

18,240 lb.	61,851 lb.	32,818 lb.
243 flasks	824 flasks	437 flasks

Mineral industry in South Africa in 1913. Board of Trade J., Oct. 29, 1914. [T.R.]

THE Report of the South African Mines Department for 1913 states that the total value of the mineral output of the Union for the year was £52,924,990, as compared with £52,711,761 in 1912. The following table shows the production of the chief minerals :—

	1912.	1913.
	£	£
Gold	38,691,688	37,374,553
Silver*	124,374	115,822
Diamonds	10,061,489	11,389,807
Coal	1,999,378	2,240,458
Coke	11,980	15,862
Copper	556,978	507,856
Tin	367,699	436,550
Asbestos	18,882	16,028
Graphite	1,155	1,257
Magnesite	1,673	1.194
Lead	8,654	1,199
Salt	63,059	77.142
Lime	129,470	118,984
Flint	9,395	3,789

* Contained in gold bullion and base metal ores.

The industrial disturbances of July, 1913, which resulted in a diminution in the number of natives employed on the Witwatersrand for the remaining six months of the year, were responsible for the decreased output of gold and silver. The slight falling off in the copper exported will probably be continued in future years as the Namaqualand mines become worked out ; the output of the northern Transvaal will, however, tend to meet the deficiency in Namaqualand.

Pig iron production in Germany in July and August, 1914. Board of Trade J., Oct. 29, 1914. [T.R.]

The Union of German Iron and Steel Workers has published the following figures of pig-iron production in Germany :—

	July, 1914.	Aug., 1914.
	Metric tons.	Metric tons.
Foundry iron	259,912	97,788
Bessemer iron	19,076	23,162
Thomas iron	1,045,586	390,658
Steel iron and spiegeleisen	203,968	100 305
Puddled iron	35,773	14,014
	1,564,315	625,927

Ferro-alloys from France; Supplies of ——. Board of Trade J., Oct. 22, 1914. [T.R.]

H.M. Embassy in France reports that, in view of the export and transport difficulties occasioned in France by the war, British firms desirous of obtaining the assistance of the Embassy in facilitating the despatch of supplies of ferro-alloys from the Republic are recommended to communicate in the first place with the Under Secretary of State for Foreign Affairs, Foreign Office, London, S.W., in order that H.M. Embassy may be instructed to intervene in cases where such action may appear desirable.

Lead, tin, and the war. Engineering, Oct. 30, 1914. [T.R.]

In consequence of the war, considerable disturbance has arisen in the markets of these metals. The world's production of lead and tin during recent years has been as follows, in tons :—

	1910.	1911.	1912.	1913.
Lead	1,127,000	1,136,000	1,181,800	1,186,700
Tin	114,800	117,600	124,700	128,900

The world's production of raw lead has been obtained from the United States, Mexico, and Canada, 487,000 tons ; Australia, 116,000 tons ; Spain, 203,000 tons ; Germany, 181,000 tons ; Austria, 24,000 tons ; Belgium, 50,800 tons ; Great Britain, 30,500 tons ; France, 28,000 tons ; and Italy, 21,700 tons. The consumption has been as follows : United States, 401,300 tons ; Germany and Austria, 259,000 tons ; Great Britain, 191,400 tons ; France, 107,600 tons. The German-Austrian production is 54,000 tons less than their consumption, and there may consequently be a shortage in those countries during the war, which may, however, be neutralised by Germany acquiring the Belgian and Italian output. Of tin, half the world's production is obtained from the Straits Settlements, 65,640 tons ; the tin produced in Europe is essentially derived from imported ores, the bulk of which is exported from Bolivia, and smelted in England and Germany. One-sixth of the world's output of tin is produced in Great Britain. It is possible that the war may curtail the world's lead output by more than 200,000 tons. The export of lead from the United States is an important factor ; it would appear that unless the output there can be increased, we cannot expect to receive much larger supplies from America, as the home consumption there is steadily increasing. British imports of lead ore and lead have been as follow during recent years :—

	Lead ore.		Pig and sheet lead.	
	Tons.	£	Tons.	£
1909	15,542	120,540	207,660	2,705,000
1911	17,259	135,010	213,707	2,902,000
1913	18,453	184,930	204,136	3,718,000

The pig lead during 1913 was imported chiefly from Spain and Australia.

Our imports of tin ore during recent years have been :—

	Tons.	£
1909	24,086	1,621,000
1911	28,837	2,306,000
1913	34,592	3,308,000

About two-thirds came from Bolivia. The Bolivian output has increased from 29,400 tons in 1908 to 37,700 tons last year. Our imports of tin blocks, ingots, bars, and slabs have been as follow :—

	Tons.	£
1909	41,725	5,603,000
1911	45,906	8,739,000
1913	45,682	9,252,000

These came mainly from the United States, Russia, and the Straits Settlements.

Blast-furnace coke. Simmersbach. *See* IIa.

Blast-furnace coke. Koppers. *See* IIa.

Talbot slag. Dafert. *See* XVI.

Patents.

Steel alloy. S. S. Wales, Munhall, Assignor to Carnegie Steel Co., Pittsburgh, Pa. U.S. Pats. (A) 1,111,710 and (B) 1,111,711, Sept. 22, 1914 ; date of appl., Dec. 27, 1909.

An alloy-steel containing (A) Mn and % Ni 4, Cr 2, and Ti 2 ; (B) C, Mn, Cr, and % Ni 0·99 and V 0·15.—W. E. F. P.

Armour-plate. S. S. Wales, Munhall, Assignor to Carnegie Steel Co., Pittsburgh, Pa. U.S. Pat. 1,111,709, Sept. 22, 1914 ; date of appl., Aug. 1, 1906.

An alloy-steel containing Ni 5—12, Cr 0·15—0·25, W 0·5—0·7, Si up to 0·15, and Mn up to 0·35%.—W. E. F. P.

[*Steel*]. *Method of hardening and tempering.* J. Patten, Baltimore, Md. U.S. Pat. 1,112,087, Sept. 29, 1914 ; date of appl., Aug. 15, 1912.

A stream of cold fluid is directed upon the surface of the metal while the latter is traversed by an electric arc. —W. E. F. P

Steel or malleable iron; Process of converting cast-iron into ——. J. A. Hunter, Philadelphia, Pa. U.S. Pat. 1,112,909, Oct. 6, 1914 ; date of appl., June 3, 1913.

Cast-iron, at a high temperature but below the melting-point, is subjected to the action of nitric acid, and then cooled, " in a suitable mechanical device."—W. E. F. P.

Metals [*gold and silver*]; *Extraction of* —— *from ores.* E. C. R. Marks, London. From J. Caldwell, Mexico. Eng. Pat. 15,711, July 8, 1913.

The ore is crushed and ground in a solution of common salt or sea water, then mixed with more salt solution, agitated by compressed air, and subjected in a closed vessel to the action of an electric current to generate chlorine, which converts the gold and silver present into soluble compounds. During this treatment the gases evolved are led to a compressor and then returned and used to agitate the charge.—A. S.

Ores of silver and gold; Treating complex refractory —— C. C. Titus, Assignor to Montana Metallurgical Co., Helena, Mont. U.S. Pat. 1,111,976, Sept. 29, 1914 ; date of appl., Dec. 14, 1910.

The ore, containing iron, another metal, and a metalloid, is agitated and heated, and treated with a gaseous mixture of chlorine and oxygen at a gradually increasing temperature, not exceeding 250° C., which is insufficient to cause fusion and agglomeration. The iron is oxidised and the second metal and metalloid converted into chlorides, the metalloid chloride being vaporised.—B. N.

Amalgamator. C. R. Dennison, Youngstown, Ohio. U.S. Pat. 1,111,251, Sept. 22, 1914; date of appl., June 4, 1913.

Between a shaft and a cylinder mounted thereon is a helical blade the edge of which engages with the shaft and with the inner surface of the cylinder to form a continuous spiral passage. The cylinder and the helical blade are of foraminous material, and the whole is rotated in a cylindrical casing containing mercury in its lower part. Ore is fed in at one end of the spiral passage and tailings discharged at the other end. Amalgam is drawn off from the bottom of the casing and mercury fed in at the top and distributed over the rotating cylinder.—A. S.

Vacuum-filters for cyanide process; Leaf of ——. Y. Ohtsuka, Tokyo, Japan. U.S. Pat. 1,111,609, Sept. 22, 1914; date of appl., Feb. 4, 1914.

A supporting bar carries depending rods of bamboo spaced apart, and horizontal strips are arranged on both sides of the rods to form perforated mats, leaving clear vertical passages between the rods. A U-shaped suction pipe carried by the supporting bar has openings in the upper side of its lower horizontal portion communicating with the vertical passages, and the mats and suction pipe are covered by filter-cloths.—A. S.

Zinc; Separation of —— from sulphide ores. H. T. Durant, and The Metals Extraction Corporation, Ltd., London. Eng. Pats. 21,581, Sept. 24, and 22,761, Oct. 8, 1913.

Sulphide ore is roasted to produce as much sulphate as possible, and leached several times, in a filter-press, with a solution of sulphur dioxide, the liquid from the first leaching being oxidised by aeration, treated with zinc dust to remove copper, evaporated to precipitate zinc sulphate, and the mother-liquor from the latter, together with the relatively weak zinc solutions from the second and subsequent leachings, oxidised, diluted if necessary, saturated with sulphur dioxide from the furnace gases, and used for leaching a further quantity of ore.—W.E.F.P.

Zinc; Process of extracting —— from its ores or compounds. E. E. Watts, Kingston, Ontario. U.S. Pat. 1,111,201, Sept. 22, 1914; date of appl., Nov. 20, 1913.

The material is mixed to a thin paste with a solution of zinc sulphate substantially free from iron and placed in the anode compartment of an electrolytic cell. The zinc is then deposited electrolytically using as electrolyte zinc sulphate solution (12% Zn) to which an organic substance is added to render the deposit dense and compact. —A. S.

Zinc residues; Treatment of ——. A. Jones, Bartlesville, Okla., Assignor to Bartlesville Zinc Co., New York. U.S. Pat. 1,112,010, Sept. 29, 1914; date of appl., July 5, 1911.

The zinc residue is arranged in a pile in the open air, and concentrated by combustion of its carbon content, the volatilised zinc being caught in the outer layer of the pile. The operation is conducted under conditions which cause the concentrated mass to sinter.—B. N.

Rabbling appliances for mechanical ore roasting furnaces. J. Harris, Sheffield. Eng. Pat. 21,897, Sept. 29, 1913.

The rabble arms are fixed in hollow lugs on the hollow shaft. Cooling water is led from a tank to the rabble arms, through pipes passing through the shaft; each feed pipe is divided, the upper portion being fixed to the tank, and entering the lower portion loosely above or about the top of the shaft, *e.g.*, by dipping into a funnel-like enlargement. The tank may be annular in form, and surround the top part of the shaft, over which is a removable casing connected with a means for sucking or forcing air through the shaft. A removable bend from each feed pipe leads through the shaft to the loose joint, and the water pipes inside the shaft are extended to a point higher than the level of liquid in the tank.—B. N.

Roasting furnaces; Rabble arms for ——. H. H. Stout, New York. Eng. Pat. 15,643, June 30, 1914. Under Int. Conv., Dec. 4, 1913.

The rabble arm consists of an outer and an inner tube connected by telescopic joints with the outer and inner walls respectively of the vertical double-wall rotary shaft. The free end of the outer tube is closed; that of the inner tube is open and prevented from abutting on the former by a stop.—W. E. F. P.

Screening apparatus for ores and the like. H. A. Megraw, New York. Eng. Pat. 9986, Apr. 22, 1914. Under Int. Conv., May 1, 1913.

A horizontal, rotary, tubular screen, open at both ends and having narrow radial shelves disposed along the inside. Ore pulp is fed to the lower part, the over-size being carried upwards upon the shelves and discharged into a central, inclined launder.—W. E. F. P.

Reducing ores; Method of ——. R. S. Wile, Pittsburgh, Pa. U.S. Pat. 1,111,049, Sept. 22, 1914; date of appl., Dec. 2, 1913.

The ore is fed into the upper part of a deep bath of slag through the central portion of which an electric current is passed vertically. The bath is kept at a substantially constant depth and is of sufficiently high density to support the superincumbent charge of ore until any volatilisable materials therein are expelled.—A. S.

Reducing ores; Apparatus for and method of ——. R. S. Wile, Pittsburgh, Pa. U.S. Pats. 1,111,050 and 1,111,341, Sept. 22, 1914; dates of appl., Feb. 3, 1914, and Dec. 15, 1913.

The furnace comprises a shaft opening at the bottom into an enlarged crucible of greater depth than the diameter of the opening. The crucible is provided with one bottom electrode and two upper ones, movable vertically, one on either side of the shaft. A bath of slag is maintained in the crucible and surrounds and protects the exposed ends of the upper electrodes. Ore is fed in through the shaft, and the electrodes are connected with the conductors of a multiphase circuit and are kept at a substantially equal distance apart so as to maintain an uniform temperature throughout the bath.—A. S.

[*Tungsten.*] *High-fusing metals and alloys of the same; Process for the manufacture of ductile bodies of ——.* A. J. Liebmann, Assignor to N. Hofheimer, New York. U.S. Pat. 1,111,698, Sept. 22, 1914; date of appl., June 3, 1914.

A highly compressed mixture of metallic tungsten powder with 1% WO_3 is subjected to a combined reducing and sintering operation.—W. E. F. P.

Copper ores [*argentiferous*]; *Process for the treatment of ——, and the recovery of their values.* C. S. Vadner, Salt Lake City, Utah. U.S. Pat. 1,111,874, Sept. 29, 1914; date of appl., Dec. 9, 1913.

The oxidised ore is agitated with a hot solution of sodium chloride saturated with sulphur dioxide; the excess of the latter removed from the solution by aeration; finely divided calcium carbonate added to the hot liquid to precipitate iron and arsenic; and the cold filtrate treated with calcium carbonate and compressed air. The precipitated basic copper carbonate (containing silver) is treated with dilute sulphurous acid, and the solution passed over metallic iron after the removal of sulphur dioxide by aeration.—W. E. F. P.

Copper extraction; Recovery of values from the leach-water of ——. C. A. Hall, Mount Airy, Assignor to Pennsylvania Salt Manufacturing Co., Philadelphia, Pa. U.S. Pat. 1,112,608, Oct. 6, 1914; date of appl., Oct. 14, 1912.

In the treatment of "cinders" by successive leachings with a solvent, the first solution is treated for the recovery of copper and other salts, and subsequent solutions for copper alone.—W. E. F. P.

Heat-treating apparatus [for metals, etc.]. J. J. Lichter, St. Louis, Mo. U.S. Pat. 1,112,074, Sept. 29, 1914; date of appl., May 7, 1914.

The heating chamber is situated above a dipping tank and has a movable floor, supported by a cradle within the liquid, and adapted to be immersed in the latter by lowering the cradle down an inclined track within the tank.—W. E. F. P.

Annealing-furnaces. J. A. and J. C. Swindell, Pittsburgh, Pa. U.S. Pats. (A) 1,112,236 and (B) 1,112,237, Sept. 29, 1914; date of appl., Dec. 12, 1913.

(A). Flues for air, gas and waste gases are arranged longitudinally beneath the floor of the heating chamber, along the middle of which a low wall extends in the same direction as the flues; inlet ports (communicating with the air and gas passages) are situated along each side of the middle wall, and outlet ports (communicating with the waste-gas flues) along the opposite outer walls of the chamber. (B.) The middle wall is hollow, forming a preheating chamber the lower part of which communicates with air and gas flues, and the upper part—by lateral openings along each side—with the interior of the chamber.—W. E. F P.

Fume-concentrator for smelters. S. W. Smith, San Jose, Cal. U.S. Pat. 1,112,860, Oct. 6, 1914; date of appl. March 9, 1912.

The fumes are passed through a horizontal chamber having a series of hollow, water-cooled, baffles extending from the floor and roof alternately; the chamber is connected at one end with the smelter and at the other with a small chamber containing rotating paddles upon which a stream of water or "reagent" is directed. A spray of reagent is also directed upon the face of each baffle and into the conduit leading from the smelter to the first chamber.—W. E. F. P.

Iron and steel; Process of producing —— directly from the ore. K. A. F. Hiorth, Christiania. U.S. Pat. 1,112,007, Sept. 29, 1914. Date of appl., June 13, 1912.

See Fr. Pat. 449,212 of 1912; this J., 1913, 492.—T. F. B.

Cupola-furnace. E. Schürmann, Koetzschenbroda, Germany. U.S. Pat. 1,112,846, Oct. 6, 1914. Date of appl., March 8, 1913.

See Fr. Pat. 458,242 of 1913; this J., 1913, 1074.—T. F. B.

Alkali metal alloys; Production of —— by the electrolysis of alkali hydroxide in the molten state, and the obtainment therefrom of alkali metals and alkali metal compounds. E. A. Ashcroft, London. Eng. Pat. 25,144, Nov. 4, 1913.

See Fr. Pat. 464,951 of 1913; this J., 1914, 489.—T. F. B.

XI.—ELECTRO-CHEMISTRY.

Accumulator; The alkaline ——. E. Friederich. Elektrochem. Zeits., 1913, 20, 6—10, 31—34.

Attempts to make plates by reducing nickel oxide or by gniting pastes of nickel or iron powder and tar failed. A atisfactory nickel peroxide plate was produced by nickelplating linen fabric carbonised at 1400° C. and extracted with hydrochloric acid. As an anode, such a plate lost carbon in continually diminishing quantities. It was "formed" by covering it with dry nickel oxide, binding it upon a nickel sheet, and charging it in caustic potash solution, using a zinc cathode.—O. E. M.

Distribution of the overhead electrical discharge employed in recent agricultural experiments. Jorgensen and Priestley. *See* XVI.

Water purification by ozone. Pryer. *See* XIXB.

Patents.

Electrolytic apparatus. J. T. Niblett, Denmark Hill, Surrey. Eng. Pat. 24,560, Oct. 29, 1913.

The element comprises a straight vertical casing, which may be divided into two or more compartments, each containing a pair of electrodes. The ends of the casing are perforated at the bottom and top, for the admission of electrolyte and the escape of air respectively. The electrodes may be sheathed in a porous covering, which does not interfere with the electrolytic action, *e.g.*, infusorial earth or asbestos.—B. N.

Cell; Electrolytic ——. C. C. Titus, Assignor to Montana Metallurgical Co., Helena, Mont. U.S. Pat. 1,111,977, Sept. 29, 1914; date of appl., Dec. 14, 1910.

The cell is separated by a diaphragm and a perforated cathode into two compartments, with a gas-tight chamber at the upper end of the anode compartment, and means for maintaining a partial vacuum in it. An overflow pipe, extending from the chamber downwards into the outer compartment, is sealed by the liquid therein.—B. N.

Furnaces; Electric resistance ——. J. Davies and A. Gallenkamp and Co., Ltd., London. Eng. Pat. 10,415, April 27, 1914.

Two opposing walls of refractory material are coupled together and maintained in fixed relationship by a number of metallic tie rods, and a combustion tube, muffle, or similar receptacle is supported in suitable recesses in the walls. The remaining walls are formed by several removable lagging blocks. A heating coil is carried upon the combustion tube, and is connected electrically with some of the rods, with means for short-circuiting the whole or a part of the current when a certain temperature is attained.—B. N.

Condenser; Electrical ——. J. W. Aylsworth, East Orange, N.J., Assignor to Halogen Products Co., Glen Ridge, N.J. U.S. Pat 1,111,289, Sept. 22, 1914; date of appl., Nov. 8, 1913.

Electrically-conducting members are separated by insulating dielectric members, the latter consisting of a solid halogen product of a hydrocarbon, such as naphthalene, mixed with a small percentage of a miscible phenolic resin.—B. N.

[Electrical] Condenser. P. Thomas, Wilkinsburg, Pa., Assignor to Westinghouse Electric and Manufacturing Co U.S. Pat. 1,112,397, Sept. 29, 1914; date of appl., Dec. 4, 1913.

The condenser has a dielectric comprising a halogen derivative of a fatty acid, such as a chlorine-substitution product of stearic acid, the chlorine being generated electrically.—B. N

Furnace; Induction electric ——. W. S. Moody, Schenectady, Assignor to General Electric Co., New York. U.S. Pat. 1,113,134, Oct. 6, 1914. Date of appl., Oct. 18, 1906.

See Eng. Pat. 26,867 of 1906; this J., 1907, 1054.—T. F. B.

XII.—FATS; OILS; WAXES.

Palm kernels; The trade in ——. Bull. Imp. Inst., 1914, 12, 458—464.

Attention is called to the importance of the trade in palm kernels, particularly in Germany where 241,961 tons valued at £5,233,252 were imported to Hamburg in 1913; the oil is extracted or expressed and used for the same purposes as coconut oil, viz., in the manufacture of soaps and candles and of various edible fats, while the meal is much used as cattle food. The possibility of this trade being diverted to the United Kingdom is discussed; no difficulty should be experienced in finding a market for the oil, but the conservative attitude of British farmers might render the disposal of the residual meal somewhat difficult. Manufacturers would probably have to depend at first on its utilisation in compound cakes, although its high reputation in Germany should cause it to become popular; while the fact that over 400,000 tons of various feeding cakes valued at £2,539,892 were imported to the United Kingdom in 1913 shows that there is room for expansion. —R. G. P.

Coconuts in Zanzibar. F. C. McClellan. Bull. Imp. Inst., 1914, 12, 420—422.

The planting of coconuts has increased of late years and there are probably about 2½ million trees on an area of 45,000 acres. Zanzibar copra is not generally of good quality owing to careless preparation, but a small consignment of sun-dried copra prepared on Government plantations compared favourably with Malabar coast copra. In 1913, 7412 tons of copra were exported from Zanzibar and Pemba principally to Marseilles. Conditions are very favourable for coconut planting and considerable areas of land await development.—R. G. P.

Cottonseed products; Changes in official methods of analysis of ——. Chemists' Committee of Interstate Cottonseed Crushers' Assoc.; Oil, Paint, and Drug Rep., 1914, 33.

At a meeting on Aug. 10 and 11, the Committee adopted the following as official methods of analysis:—*Moisture:*—Two to 5 grms. are dried for 3 hours in a covered aluminium dish (of special form, obtainable from American Can Co., Atlanta, Ga.) in an oven at 100° C. *Oil:*—Two to 5 grms. are extracted for 3 hours, in a Soxhlet extractor with short siphon, with petroleum spirit (b. pt. less than 65° C.). *Nitrogen:*—1·7034 grms. are digested and heated with about 0·5 grm. of mercury or 0·7 grm. of mercuric oxide, 10 grms. of sodium or potassium sulphate, and 25 c.c. of sulphuric acid (sp. gr. 1·84) until the solution is colourless. It is then diluted with 300 c.c. of water (fragments of zinc added to prevent bumping), and treated with 25 c.c. of 4% potassium sulphide and 60 c.c. of sodium hydroxide solution (sp. gr. 1·50), the flask connected with a tin condenser, and the ammonia distilled into standard sulphuric acid. *Fat in cottonseed meal:*—The official methods of the Amer. Assoc. Off. Agric. Chemists must be used. *Total fatty acids:*—8 to 10 grms. of soap stock or 4 to 5 grms. of black grease are saponified with alcoholic alkali, the soap solution evaporated to expel alcohol, dissolved in 200 to 250 c.c. of water, and the fatty acids liberated with dilute hydrochloric acid (1 : 1), cooled, separated, washed on the filter with cold water, dried (preferably overnight), and dissolved in 125 c.c. of warm petroleum spirit, the solution evaporated, and the residue dried at 100° C. until constant in weight. A correction is made for oil subsequently recovered from the melted soap stock. *Moisture and meal in crude cottonseed oil:*—10 grms. are heated in a basin over a direct flame until the oil begins to smoke, and the loss in weight taken as moisture. The residue is transferred to a Gooch crucible, washed with petroleum spirit until free from oil, and the final residue of meal, etc., dried until constant in weight. *Free fatty acids in crude cottonseed oil:*—About 50 c.c. of neutral sodium chloride solution (20° B., sp. gr. 1·1612) are placed in a 4 oz. bottle, 1 c.c. of phenolphthalein solution added, and 7·05 grms. of the oil introduced with a standard pipette (obtainable from G. C. Hulbert, Augusta, Ga.), and the mixture shaken and titrated with *N*/4 sodium hydroxide solution. *Laboratory refining test for prime crude cottonseed oil:*—500 grms. are brought to 24° to 27° C. in a weighed enamelled basin about 4½ in. by 4 in., sodium hydroxide solution of the required strength (see table below) added, the mixture mechanically stirred for 5 mins., warmed gradually (in not less than 15 mins.) to 34° C. on the water-bath, with continual stirring, until the oil separates from the soap-stock. If necessary the temperature is raised to 52° C. The basin is then placed in water at 43° C. for 3 hours, and allowed to cool until the soap-stock is hard. The loss in weight due to evaporation is determined, the oil decanted into a weighed basin, and oil and soap-stock separately weighed. The quantity of sodium hydroxide used for refining prime oil must not exceed 1·097%. The following table gives the corresponding quantities of the different strengths of solution which can be used:—

° B.	Sp. gr.	NaOH %	Amounts. %
10	1·0745	6·55	16·8
12	1·0909	8·00	13·7
14	1·1076	9·42	11·6
16	1 1249	10·97	10·0
18	1·1427	12·62	8·7
20	1·1612	14·37	7·6

Tests with 3 or more solutions of the strengths in this table must be made before rejecting a sample; no claim for excessive refining loss is to be allowed if it can be proved that the colour can be obtained with smaller loss than that produced with the maximum permissible amount of sodium hydroxide; and no claim for deficiency in colour is established if it can be proved that the colour can be obtained without exceeding 9% refining loss with the maximum permissible amount of sodium hydroxide. *Refining loss:*—This equals (1) weight of crude oil less weight of refined oil; (2) weight of soap stock, less weight of alkali solution used, plus loss in evaporation. The two results should agree within 0·25%. *Laboratory refining test for "off" (acid) crude cottonseed oil:*—The following table shows the maximum amount of sodium hydroxide that can be used with oils containing the indicated amounts of free fatty acids:—

Free fatty acids. %	Sodium hydroxide. grms.	Excess. grms.	10° B. %	12° B. %	14° B. %	16 °B. %	18° B. %	20° B. %	22° B. %	24° B. %

Oils containing less than 3% free fatty acids may be refined with any amount of sodium hydroxide solution containing up to 1·007 grms. *Process* :—Free fatty acids are determined by the official method and the oil treated as described above with sodium hydroxide solution at 24° to 27° C., with the exception that the temperaturo is brought to 60° C. and eventually to 65° C. Three tests must be made with different strengths of alkali, one of them with the maximum permissible amount. *Bleaching refined cottonseed oil* :—30 grms. of oil are agitated for 5 mins. at 120° C. with 6% of standard English fuller's earth, to be obtained from R. Hulme, Phœnix Cotton Co., Memphis, Tenn., and filtered, and a reading taken with 5¼ in. of the clear oil at 21° C. *Hull analysis* :—5 grm. of the hulls freed by hand-picking from whole seeds) are extracted for 4 hours in a Soxhlet apparatus with petroleum spirit boiling below 65° C., as described above. Whole seed is calculated into oil % by use of the factor 0·20.—C. A. M.

Cottonseed oil ; Ethyl ester of linolic tetrabromide as a product in the analysis of ——. L. S. Palmer and P. A. Wright. J. Ind. Eng. Chem., 1914, **6**, 822—823.

N attempts to isolate linolic acid as the tetrabromide rom cottonseed oil, in which the unsaturated acids were eparated by the lead soap-ether method of Tortelli and Ruggeri (Lewkowitsch, " Oils, Fats and Waxes (1909), Vol. I, 447), in some cases large clustering needles, m. pt. 58—58·5° C., were obtained instead of linolic tetrabromide of m. pt. 113°—115° C. Analysis of the new product howed it to be the ethyl ester of linolic tetrabromide, $C_{17}H_{31}Br_4CO_2C_2H_5$, and this was confirmed by its preparation from linolic tetrabromide by esterification with alcohol and hydrochloric acid gas. The formation of the ethyl ester was probably due to prolonged contact of the ead soaps with ether ; with varying periods of contact, mixtures of linolic tetrabromide and its ethyl ester in varying proportions were obtained. The authors have also prepared methyl bromolinolate (white plates, m. pt. 50°—56° C.) and the methyl and ethyl esters of oleic dibromide, yellow oils very soluble in most solvents. The sters of linolic tetrabromide are very soluble, whereas hose of oleic dibromide are very sparingly soluble, in their orresponding alcohols saturated with hydrochloric acid, but attempts to utilise this difference in properties to separate oleic and linolic acids proved unsuccessful.—A. S.

Kapok seed from Zanzibar. Bull. Imp. Inst., 1914, **12**, 347.

THE seeds contained a normal amount of oil, viz., 21% and would be saleable at current market prices. The principal European market is Rotterdam where the seeds fetch about £6 10s. per ton —R. G. P.

Moringa pterygosperma seed from Zanzibar. Bull. Imp. Inst., 1914, **12**, 348—349.

THE seed contained only 28·6% ofoil, while a previous sample from N. Nigeria contained 35%. The seeds would be saleable if exported in quantity but the market value is uncertain owing to the presence of traces of alkaloids and of much non-albuminoid nitrogenous substances which might render impossible the use of the cake as cattle-food.—R. G. P.

Marine animal oils ; Specific reaction of —— *and of their products of hydrogenation.* M. Tortelli and E. Jaffe. Annali Chim. Appl., 1914, **2**, 80—98.

ONE c.c. of the oil is dissolved in 6 c.c. of chloroform and 1 c.c. of glacial acetic acid and shaken vigorously with 40 drops of a 10% solution of bromine in chloroform. In the case of marine animal oils a characteristic reaction is obtained within 1 minute, comprising a transient pink colour changing to a clear green which persists for more than 1 hour. With other oils either no reaction or a yellow colour is obtained. The reaction is also given by hardened oils obtained by hydrogenation of marine animal oils. 5 c.c. of the melted fat are dissolved in 10 c.c. of chloroform and 1 c.c. of glacial acetic acid and shaken with 2·5 c.c. of a 10% solution of bromine in chloroform : a yellowish pink colour changing quickly to green is produced.—A. S.

Hydrogenated fats ; Industrial production of ——. G. Verona-Rinati. Annali Chim. Appl., 1914, **2**, 99—105.

AN apparatus is described for the hydrogenation of oils, using palladium precipitated on small pieces of coke as catalyst. The catalyst is placed in a movable support kept in motion by a rotating spindle connected by gearing with a pulley outside the reaction chamber. The preheated oil is sprayed into the upper part of the chamber by means of hydrogen under pressure, and a pressure of about 2 atmospheres is maintained inside the chamber. Three reaction chambers are provided and the oil may be withdrawn after one, two, or three treatments in presence of the catalyst, according to the degree of hydrogenation desired. The hydrogen is obtained from water-gas by the Frank-Caro-Linde process of refrigeration, and the excess coming from the reaction chambers is returned to the refrigerating apparatus for purification. When the catalyst loses its activity, it is washed in the apparatus with an inert solvent (petroleum spirit), the last traces of the latter are expelled by a current of steam, and the palladium is again rendered active by treatment with hydrogen at not above 150° C. Palladium possesses the advantage of being active at a considerably lower temperature than nickel (*e.g.*, at 80°—90° C.). According to Karl it loses its activity when deposited on lead, iron, aluminium or zinc, but remains active on finely-divided nickel or on magnesium. —A. S.

Fixed oils of the British Pharmacopœia, 1914. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 380—381.

In the new Pharmacopœia limits for acid, saponification and iodine values of the fixed oils are given, as well as special tests for common adulterants. The figures are summarised in the following table :—

Oleum.	Sp. gr.*	Ref. ind. (40°).	Sapon. value.	Iodine value.	Maximum acid value.
Amygdalæ	0·915—0·920	1·4624—1·4640	188—196	93—100	6
Arachis	0·916—0·921	1·4628—1·4645	190—196	83—101	6
Lini	0·930—0·940	1·4725—1·4748	187—195	Not less than 170	3
Olivæ	0·915—0·918	1·4605—1·4635	188—197	79—87	6
Sesami	0·921—0·924	1·4650—1·4675	189—193	103—114	8
Theobromatis	0·990—0·998	1·4565—1·4575	188—195	35·5—37·5	2

* Temperature not stated.

—F. Sidn.

Sterols; Isolation of —— from fats by means of digitonin. P. Berg and J. Angerhausen. Chem.-Zeit., Aug. 4, 1914. Pharm. J., 1914, **93**, 525.

Since Windaus (Ber., 1909, **42**, 244) showed the possibility of isolating sterols from fats by means of digitonin many authors have tried to adapt this discovery for practical analysis. The method used by the present authors is as follows :—The melted and filtered fat is shaken for a quarter of an hour with a 1% alcoholic solution of digitonin, the temperature of the mixture being 60°—70° C. Chloroform is then added, and after some time (care being taken that the temperature remains 60°—70° C.), the chloroform-fat solution is filtered and the filter freed from fat by chloroform. Through the same filter, the alcohol, containing most of the digitonide, is passed, and the digitonide washed with ether and dried. It is then converted into sterol acetate by boiling with acetic anhydride. After being cooled, the liquid deposits crystals of sterol-acetate. The crystals are dissolved in ether, the solution is filtered, the ether evaporated, and the acetate is recrystallised from alcohol. The melting-point of the sterol-acetate is used as a means to identify cholesterol and phytosterol. The following melting-points were found :—

Cholesteryl acetate from lard (after one crystallisation) = 113·5° C.
Cholesteryl acetate from tallow („ „ „) = 113° C.
Phytosteryl acetate from Oleum Cocois („ „ „) = 127° C.
Phytosteryl acetate from cotton-seed oil („ „ „) = 123° C.

A similar method is used to free the unsaponifiable matter of a fat from sterols. The fat is dissolved in absolute alcohol and an alcoholic solution of digitonin is then added, and after adding a few c.c. of water the digitonide is deposited as flocks, which become crystalline after some time. (See also this J., 1913, 1118.)

Silicates in soap; New qualitative test for ——. H. W. Leitch. J. Ind. Eng. Chem., 1914, **6**, 811—812.

A solution of the soap is heated with excess of hydrochloric acid, the fatty and other insoluble matter filtered off, the filtrate neutralised, boiled with alcoholic potash, filtered and the filtrate (10 c.c.) poured into a mixture of 10 c.c. of acetone and 1 c.c. of a solution containing 10 grms. of sodium aluminate and 2 grms. of sodium chloride per litre : the formation of a precipitate of aluminium silicate indicates the presence of silicates (water-glass). Dextrin or starch also give a precipitate and, if present, should be removed, before boiling with alcoholic potash, by treatment with " Diastafor " at 35° C. for ½ hour.—A. S.

Patents.

Lard substitute [hydrogenised oil]; Apparatus for making ——. J. C. Chisholm, Assignor to The Chisholm Process Oil Refining Co., Dallas, Tex. U.S. Pat. 1,113,151, Oct. 6, 1914; date of appl., Oct. 8, 1912.

Oil and hydrogen are admitted into the opposite ends of a rotating perforated drum around which is wound spiral layers of wire, " having its engaging surface of a catalytic agent." The drum is enclosed in a casing. —W. P. S.

Fullers' earth [from oil refining]; Process of treating ——. C. L. Parsons, Durham, N.H. U.S. Pat. 1,112,650, Oct. 6, 1914; date of appl., Aug. 29, 1906.

Spent fullers' earth from oil-refining works is treated first with a solvent which will dissolve the residual oil but not the absorbed colouring matters, and then with a solvent for the extraction of the colouring matters. —W. P. S.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Isoprene from commercial turpentines. Herty and Graham. *See* XX.

Patents.

Woods; Process for extracting from —— their solubl contents. I. S. Clope, Wilkinsburg, Pa., Assignor t Empire Chemical Co., Atlanta, Ga. U.S. Pat. 1,112.359 Sept. 29, 1914. Date of appl., Oct. 22, 1913.

Coniferous woods are treated under reduced pressur with the vapour of trichloroethylene, the vapours ar allowed to condense, and the resulting solution i fractionated to obtain acetone, methyl alcohol, turpentine pine oil, and resin.—T. F. B.

[Rosin] extractor. J. H. Castona, Moss Point, Miss. Assignor to Castona Improved Process Co., Gulfport Miss. U.S. Pat. 1,112,980, Oct. 6, 1914; date of appl. May 7, 1912.

The material (wood) to be treated is supported in perforated cage within a closed vertical cylinder. vertical perforated steam pipe extends from the cove to the bottom of the cage, there is a steam coil immediatel beneath the cage, and the base of the cylinder is hollo for the passage of steam. The vapours are led awa from the top of the cylinder and rosin collects on the steam-heated base.—A. T. L.

Phenolic condensation product and method of forming the same. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,111,285, Sept. 22, 1914; date of appl., June 2, 1911.

The product comprises an infusible, insoluble, condensation product of phenol and formaldehyde, containing a non-volatile nitronaphthalene derivative, which dissolves in and renders the product plastic at 350° F. (177° C.) The condensation product is free from any halogen acid, and is infusible and insoluble in alcohol and water. The naphthalene derivative melts substantially below its boiling point, and is of such character and proportion, and so united with the product, as to be incapable of removal from thin masses, or by washing the body in a finely divided form with water.—B. N.

Indurated articles; Producing ——. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,111,286, Sept. 22, 1914; date of appl., July 14, 1911.

The porous structure (*e.g.*, wood) is soaked in a solution of a hardening agent (*e.g.*, hexamethylenetetramine) of strength so as to leave approximately the desired predetermined amount of the agent within the pores on drying. The material is then dried, soaked in a solution of a predetermined quantity of a fusible, soluble, phenol resin at not above 210° F. (99° C.) and then heated to cause a reaction between the two substances, thus forming an infusible hard insoluble product in the pores of the wood.—B. N.

Cresolic varnish composition. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,111,287, Sept. 22, 1914; date of appl., June 12, 1912.

The compound comprises a fusible cresol formaldehyde condensation product, formed from a fusible cresol resin and a methylene-containing hardening agent, and having a melting point from 140° to 170° F. (60°—77° C.). It is unchangeable into an infusible product at any temperature less than that of its decomposition, and is soluble in all proportions in turpentine oil, benzene, linseed oil, Chinese wood oil, and monochloronaphthalene.—B. N.

Plastic substances; Production of ——. J. W. Aylsworth, East Orange, N.J., Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,111,288, Sept. 22, 1914; date of appl., Aug. 4, 1913.

The plastic substance, which comprises a water-soluble product containing phenol alcohols, is formed by the reaction between phenol and a methylene-containing substance such as formaldehyde, in the presence of a substantial amount of an alkaline earth hydroxide, such as calcium hydroxide. The solution is neutralised by a mineral acid, such as carbonic acid, the calcium carbonate filtered off, and the mass dried.—B. N.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Para (Hevea) rubber from the Gold Coast. Bull. Imp. Inst., 1914, **12**, 370—371.

The cultivation of *Hevea* has been very successful at Government experimental stations, notably at Aburi and Tarquah; European plantations are already producing rubber while natives also are cultivating the tree. Smoked biscuits from 13 year old trees at Aburi were clean and well prepared and would find ready sale at current market prices. They gave a washing loss of 0·8%; the dry washed rubber contained: caoutchouc, 94·1; resins, 2·9; proteins, 2·7; ash, 0·3%; comparing favourably with Eastern plantation Para rubber.—R. G. P.

Ceara rubber from Papua. Bull. Imp. Inst., 1914, **12**, 373—374.

One sample of sheet and one of scrap rubber stated to be the first produced in Papua were examined. The sheet rubber was clean, well prepared and of normal composition. It would be readily saleable at about 2s. 0d. per lb. (July, 1914). The scrap rubber was slightly tacky and probably worth about 1s. 8d. per lb.—R. G. P.

Rubber in Zanzibar. J. C. McClellan. Bull. Imp. Inst., 1914, **12**, 422.

Two trees are indigenous, *Landolphia Kirkii* and *Mascarenhasia elastica*; the majority of the small quantity of rubber exported (1 ton in 1913) is derived from the former. Ceara trees planted in 1907 in the north of Pemba were healthy, but labour and transport difficulties have prevented further experiments.—R. G. P.

Rubber wares (other than machinery belting, tyres for cycles, motor cycles, and motor cars, and toys). Board of Trade Bulletin No. 81.

Can be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Isoprene from commercial turpentines. Herty and Graham. *See* XX.

Patents.

Rubber or rubber compounds; Apparatus for waterproofing or applying —— to canvas and other fabrics. W. A. Higham, Cheshunt, and H. Skelton, London. Eng. Pat. 20,471, Sept. 10, 1913.

The fabric is passed over two guide rollers, and under a gauge, or spreading knife, provided with side cheeks, which is placed between them. Rubber solution in the trough thus formed in front of the gauge is forced by the action of the latter right through the fabric, and a further coating can then be applied by means of the ordinary gauge and roller, using ordinary "dough."—E. W. L.

Caoutchouc and the like; Manufacture of synthetic ——. F. E. Matthews and E. H. Strange, London. Eng. Pat. 22,137, Oct. 1, 1913.

A mixture of a hydrocarbon containing a conjugated double linkage (divinyl, isoprene, etc.) with sodium or other alkali metal or alloy thereof is ground during the polymerisation. The process may be accelerated by heat. The grinding is advantageous if impurities be present which would cause a deposit on the metal and so retard the reaction. (See Eng. Pat. 24,790 of 1910; this J., 1911, 1398.)—T. F. B.

Rubbers: Process for the improvement of inferior-grade ——. D. Spence and W. F. Russell, Akron, Ohio, Assignors to The B. F. Goodrich Co., New York. U.S. Pat. 1,112,938, Oct. 6, 1914. Date of appl., Feb. 12, 1912.

See Fr. Pat. 448,974 of 1912; this J., 1913, 499.—T. F. B.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning materials; Colour reactions of ——. H. G. Bennett. J. Amer. Leather Chem. Assoc., 1914, **9**, 436—442.

Characteristic colours are obtained when dilute infusions of different tanning materials are mixed with hydrogen peroxide and treated with an alkaline solution of cobalt nitrate. 6 or 7 c.c. of the infusion containing 0·1% of tannin (which need not be filtered) are treated with an equal volume of 16 vol. hydrogen peroxide and then with 3 or 4 drops of a cobalt solution, prepared by adding a concentrated solution of 2·5 grms. of cobalt nitrate to 25 grms. of ammonium carbonate in 150 c.c. of water. Characteristic colours are also obtained when a little dilute tannin infusion is largely diluted with 400 or 500 c.c. of hard water, or a very dilute solution of an alkaline salt, and 2 c.c. of a 1% solution of iodine in potassium iodide or a crystal of potassium ferricyanide in a little 10% ammonia added. By means of these colour reactions pyrogallol and catechol tannins may be differentiated and the former group subdivided into two distinct classes. The colour reactions obtained with the commoner tanning materials are :—

	Cobalt test.	Iodine test.	Ferri-cyanide test.
Pyrogallol tannins (I)			
Valonia, chestnut extract, oakwood extract	purple	dark blue	purple
Pyrojallol tannins (II)			
Gallic and gallotannic acids, sumach, myrobalans, algarobilla ..	orange	purple-red	orange
Pyrogallol-catechol tannin			
Mimosa bark	bright red	purple-red	orange
Catechol tannins			
Quebracho, gambier	bright red	no colour	orange

—T. C.

Guara ; a new tanning material. W. Eitner. Gerber, 1914, **40**, 85—86.

THE newly introduced tanning material, *guara*, is identical with a tanning material introduced 25 years ago and again at intervals under the name, *Cascalotte*. It consists of the ground fruits of a variety of divi native to South and Central America, freed from seeds and woody husks. It contains from 44 to 54% of a mixture of pyrogallol- and catechol-tannins and gives a very light-coloured, full leather. Guara is also sold as a solid extract. An analysis of this extract gave : tanning matters 41·8, non-tanning matters 30·9, insoluble matters (chiefly ellagic acid) 15·4%. The high percentage of non-tanning matters and the low percentage of tannins compared with the original material, as well as the presence of ellagic acid indicate that considerable decomposition has taken place during the manufacture of the extract or else it has been manufactured from residues containing seeds and woody husks. The extract gives a dark red-brown "empty" leather very similar to mangrove-tanned leather and is considerably inferior to the natural product.—T. C.

Tanning and tanning extracts ; Review of recent progress in ——. G. Baldracco. Annali Chim. Appl., 1914, **2**, 158—171.

ACCORDING to Armand decolorised chestnut extract gives a greater relative yield of leather than an extract which has been merely clarified.

A commission appointed by the Italian Association of the Leather Industry and Trade recommends the following limits for water, ash, and soluble organic matter in leather :—Water, determined by drying at 105° C., not above 20% ; ash, not above 2% ; soluble organic matter, not above 12%, of which saccharine substances must not be responsible for more than 2%. The soluble organic matter is determined in Koch's apparatus, 20 grms. of finely-divided leather being left in contact with water for 12 hours and then extracted for 1½—2 hours so as to obtain 1000 c.c. of solution : if the last portion of the extract still gives a precipitate with gelatin, the extraction must be continued, and the final washings concentrated. —A. S.

Dextrose in leather ; Determination of ——. F. P. Veitch and J. S. Rogers. J. Amer. Leather Chem. Assoc., 1914, **9**, 421—436.

To obtain accurate results with the von Schroeder method of clarification of leather extracts (using basic lead acetate solution), prior to determining dextrose with Fehling's solution, it is necessary to know the amount of soluble matters present other than dextrose and magnesium sulphate, as too large an excess of basic lead acetate solution removes dextrose. The method of clarification adopted by the American Leather Chemists Association (25 c.c. of saturated normal lead acetate solution to 200 c.c. of leather extract containing the soluble matters from 3 grms. of leather) gives accurate results with leathers in which the total soluble matters vary within wide limits, no dextrose being removed even if a large excess of normal lead acetate solution be used.—T. C.

Upholstery leathers ; Method of preparing washable ——. J. G. Ritter. Gerber, 1914, **40**, 58—59 and 71—73.

VEGETABLE-TANNED hides are partially de-tannised by drumming with weak alkaline solutions and then retanned with a mixture of sumach, gambier and myrobalans and aluminium sulphate, salt and magnesium sulphate, together with fish oil. They are next treated with a soap solution, set out and dried. The enamelling is carried out with linseed oil boiled with driers, and formulæ are given for preparing the ground coat, various colour coats and the final varnish (bright or matt) coat.—T. C.

PATENT.

Leather ; Method for producing a non-slip, waterproof, chrome ——. J. L. Allen, Gloucester. Eng. Pat. 21,998, Sept. 30, 1913.

DRY, chrome-tanned hides are either soaked in, or have their "flesh" surfaces brushed with, a solution consisting of shoemaker's wax (resin, tallow and Stockholm or other tar), 4, and paraffin wax, 1 lb., in benzine 4 lb. The hides are lightly washed over with benzine after this treatment, and are then dried in a current of air. (Reference is directed to Eng. Pat. 17,228 of 1912 ; this J., 1913, 38.) —E. W. L.

XVI.—SOILS ; FERTILISERS.

Soil solution and the mineral constituents of the soil. A. D. Hall, W. E. Brenchley, and L. M. Underwood. Phil. Trans., 1913, B. 204. J. Agric. Sci., 1914, **6**, 278—301.

SOLUTIONS were made by extracting the soils from certain of the Rothamsted plots on which wheat and barley had been grown for 60 years. Wheat and barley were grown in these solutions which were renewed fortnightly. The comparative growth in the solutions was closely parallel to the growth of the crops in the field, and corresponded to the composition of the solutions. The phosphoric acid- and potash-contents of the solutions corresponded to the past manurial treatment and present composition of the soils, and were of the same order as those of the natural drainage waters from the corresponding plots. Growth in the soil solutions agreed with that in artificial culture solutions containing equivalent amounts of phosphoric acid and potash. Growth in the solutions from imperfectly manured plots was brought up to the level of that in the solutions from completely manured plots by making up their deficiencies of phosphoric acid and potash. Wheat grew as well as barley in the solutions of the wheat soils, and *vice versa*. In a similar set of solutions from the same soils the growth of buckwheat, white lupins and sunflowers corresponded with that of wheat and barley. Boiling effected no alteration in the nutritive value of the soil solutions. In nutritive solutions of various degrees of dilution the growth of the plants varied directly, but not proportionally, with the concentration of the solution, though the total plant food present was in excess of the requirements of the plant. When the nutrient solution was diffused as a film over sand or soil particles, as in nature, there was no retardation of growth due to slowness of diffusion of the nutrients to the points in the liquid which had been exhausted by contact with the roots. Growth in such sand cultures was much superior to that in water cultures with the same solution, but in the latter case growth was similarly increased by the continuous passage of air through the liquid. The conclusions drawn are :—The composition of the natural soil solution as regards phosphoric acid and potash varies significantly with the composition of the soil and its past manurial history. Within wide limits the rate of growth of a plant varies with the concentration of the nutritive solution, irrespective of the total amount of food available. When other conditions, such as the supply of nitrogen, water and air, are equal, the growth of a crop will be determined by the concentration of the soil solution in phosphoric acid and potash, which in its turn will be determined by the amount of these substances in the soil, their state of combination, and the fertiliser supplied. On normal cultivated soils the growth of crops like wheat and barley, even when repeated for 60 years in succession, does not leave behind in the soil specific toxic substances which have an injurious effect upon the growth of the same or other plants in that soil. The net result of these investigations is to restore the earlier theory of the direct nutrition of the plant by fertilisers (Cp. Dyer, this J., 1894, 288; Cameron, this J., 1910, 774).—J. H. L.

Crop; The effect of one —— on another. Duke of Bedford and S. U. Pickering. J. Agric. Sci., 1914, **6**, 136—151.

The effects of growing grass over the roots of fruit and other trees has been under investigation at the Woburn Experimental Farm since 1895. The principal conclusions arrived at are:—Every growing crop results in the formation of a substance toxic to other plants, and still more so to itself. The toxin oxidises and loses its toxicity and then enhances the fertility of the soil; plants previously poisoned outgrow those not subjected to the toxin unless the toxic effect has been sufficient to produce permanent stunting. The toxic effect varies considerably, according to the nature of the soil, the plant affected and the vigour of the plant producing the toxin. The toxin is probably formed from the debris of the roots and does not appear to be excreted. Heating a soil produces a greater quantity of toxic matter from organic substances than is produced by the growth of a crop, and in this case also the oxidised toxin increases fertility.—R. G. P.

Soil; Improved electrical method of determining salt in ——. W. Beam and G. A. Freak. Cairo Scient. J., 1914, **8**, 130—133.

The most rapid method for the determination of soluble salts in soils is that based on the electrical conductivity of the extract. A convenient form of apparatus is a circular slide-wire bridge, in which, for use in dry climates, the wooden circle supporting the wire should be replaced by ebonite. Instead of saturating the soil with water for the measurement of the resistance, the authors prefer to shake with a measured excess of water and determine the resistance of the liquid; the influence of the texture of the soil is thus eliminated. The results are influenced by the temperature and by the presence of sodium carbonate and organic matter; errors due to the composition of the soluble extract in this respect must be dealt with by the use of special tables based on actual observations. For sodium sulphate the same tables as for chloride may be employed without appreciable error. On the other hand, the presence of calcium salts, particularly calcium sulphate, must be allowed for: calcium sulphate is not only harmless in itself, but neutralises to a large extent the effects of other soluble salts inimical to vegetation. Calcium sulphate may be excluded by employing, instead of water, aqueous alcohol (*e.g.*, 40% by volume) for the extraction of the salts from the soil. Further, from the difference between determinations made with aqueous and dilute alcoholic extracts of the soil, the amount of calcium sulphate may be approximately estimated. In carrying out the tests, a quantity of soil roughly equivalent to 20 grms. of dry substance is shaken in a stoppered bottle with 100 c.c. of water or 40% alcohol, preferably for 10—15 mins., and the resistance of the liquid measured without filtration. The results are calculated from tables or curves constructed from determinations made on solutions of sodium chloride in water and in 40% alcohol and of calcium sulphate in water. —J. F. B.

[*Soils.*] *Scouring lands of Somerset and Warwickshire.* C. T. Gimingham. J. Agric. Sci., 1914, **6**, 328—336.

Various "teart" pasture lands in Somerset and Warwickshire cause scouring of cattle at certain times of the year. All these lands are on the Lower Lias. The soil from "teart" land does not differ markedly from that of adjacent sound land in chemical composition or in the size of the particles, but it possesses a higher soil density, is less loose in texture, less dark in colour and contains less organic matter. Herbage from "teart" land appears less mature, softer and less fibrous than that from sound land, and contains more water and less fibre. Scouring is probably due to the physiological action of one or more constituents of the herbage which are not normally present but occur under special soil (and weather) conditions which appear to be determined by the texture of the soil and which can be removed when the texture is appropriately changed.—J. H. L.

Soil carbonates; Determination of ——. H. B. Hutchinson and K. MacLennan. J. Agric. Sci., 1914, **6**, 323—327.

Two round-bottomed bolt-head flasks of Jena glass, holding 100 and 1000 c.c. respectively, are fitted with double-bored rubber stoppers and connected by a stout bulbed tube. Through the remaining hole of the stopper of the large flask passes the stem of a separating funnel, and through that of the small flask a separating funnel of 50—70 c.c. capacity provided with a three-way tap so that the interior of the flask can be connected with a pump. The material, *e.g.*, 10 grms. of soil, is placed in the small flask. Into the funnels of the small and large flasks are introduced respectively 50 c.c. of 2% hydrochloric acid and 50 c.c. of $N/10$ sodium hydroxide, and then the apparatus is exhausted by a pump capable of giving an internal pressure of 60—100 mm. of mercury. The alkali is next run into the large flask, leaving a few c.c. in the funnel to absorb any traces of carbon dioxide which may escape through the tap. The acid is run into the small flask, which is carefully shaken after the first vigorous evolution of carbon dioxide has ceased. When all the carbon dioxide is evolved (usually after about 20 mins.) air free from carbon dioxide is drawn through the liquid in the small flask and it is again shaken occasionally. About 20—60 mins. after the admission of air, absorption is complete, the large flask is disconnected and the interior of the funnel rinsed into it with water free from carbon dioxide. The best method of titrating the liquid is to add excess of barium chloride to remove carbonates from solution, and then to titrate the free alkali alone with phenolphthalein if $N/10$ sodium hydroxide has been used for absorption. This, deducted from the reading for free alkali in the solution in a blank experiment, may be taken alone for calculation, or the barium carbonate precipitate may be further titrated against acid after the addition of methyl orange. The barium chloride solution should be added immediately before titration, since on prolonged standing the precipitate tends to form larger aggregates with a consequent slowing down of the last stage of the titration with methyl orange indicator; where this occurs a slight excess of acid may be added and titrated back with $N/10$ sodium hydroxide. The method, tested with calcium and sodium carbonates gave accurate results.—J. H. L

Soils; Relative effect of lime as oxide and carbonate on certain ——. H. B. Hutchinson and K. MacLennan. J. Agric. Sci., 1914, **6**, 302—322.

Caustic lime effects a partial sterilisation of the soil and a chemical decomposition of some of the organic matter present (see Hutchinson, this J., 1911, 471; 1913, 761; Russell and Hutchinson, this J., 1913, 501). Five different soils were analysed, treated with various amounts of lime and calcium carbonate up to 1%, and examined monthly for the quantities of ammonia and nitrate and the number of bacteria present, and pot experiments were carried out with barley and mustard. The amount of caustic lime necessary to induce specific changes in the flora and fauna of the soils was found to depend largely on the character of the soils. Light sandy Millbrook soil (from the Woburn Exptl. Fruit Farm) poor in organic matter and carbonate, reacted sharply with 0·2—0·3%; Rothamsted clay soil, poor in organic matter but rich in carbonate, reacted with 0·3—0·4%; Woburn soil (Exptl.

Station, Royal Agric. Soc.), consisting of open sandy loam rendered distinctly acid by annual applications of ammonium sulphate for 37 years, required 0·5—1%, as did also rich garden soil (Physic Gardens, Chelsea) which already contained carbonate; Craibstone soil (Exptl. Farm, North of Scotland College of Agric.) with a high organic- and low carbonate-content failed to react with 1% of lime. Each soil appeared to absorb directly a definite amount of caustic lime, and until this requirement was fulfilled the partial sterilisation phenomena did not set in. These phenomena included a sudden initial decrease and subsequent increase in the number of bacteria, the extinction of the larger forms of protozoa and the inhibition of nitrate production. Smaller doses than those required for partial sterilisation induced a temporary suspension of nitrification, and a consequent accumulation of ammonia for periods varying with the amount of lime and the character of the soil; there was also a temporary increase in the number of bacteria capable of growing on gelatin plates, but the number afterwards fell to the level of the untreated soil. The decomposing action of caustic lime on the organic matter of the soil was shown by the production of ammonia when the bacteria were quiescent; when bacterial growth commenced the production of ammonia was largely increased. The return in nitrogen (as ammonia and nitrate) for each increment of lime applied varied with the character and reaction of the soil and the carbonate-content; on the average over a period of 250 days, it amounted to 1% of the weight of lime applied. Calcium carbonate gave lower returns, apparently because of its lesser action on organic matter. The pot experiments showed amounts of available nitrogen comparable with the amounts of ammonia and nitrate produced in the laboratory experiments. In some cases the quantity of lime added was sufficient to check the growth of bacteria and to depress plant growth in the first crop; in the case of the Chelsea soil the bacteria were active but plant growth was depressed. Inhibition of nitrification resulting from the application of lime led to a higher nitrogen-content in the plants, possibly due to assimilation of nitrogenous compounds other than nitrates, an uneconomic utilisation of soil nitrogen if occurring to any extent. Where the amount of lime applied did not check nitrification the nitrogen-content of the plants was about normal.—J. H. L.

Lime requirement of soils; Determination of the —— by means of the hydroxide of the alkaline earths. C. R. Moulton and P. F. Trowbridge. J. Ind. Eng. Chem., 1914, **6**, 835—837.

THE method proposed by Bizzell and Lyon (this J., 1914, 34) for determining the lime requirement of a soil is shown to give very variable results according to the quantity of barium hydroxide used, the duration of the distillation, and the volume of the distillate.—A. S.

Soil sterility in Java. F. Ledeboer and A. E. Berkhout. Archief Suikerind. Nederl.-Indië, 1914, **22**, 653—672; Intern. Sugar J., 1914, **16**, 486.

"BLACK ALKALI" accumulations, probably originating from flooded craters, have been found to be the cause of the unproductiveness of parcels of soil in the Petaroekan district, Java. A light dressing of caustic lime, or better still gypsum, produced a remarkable improvement, but the addition of a large amount changed the structure of the soil, the lime displacing the soda in the colloidal compounds, causing flocculation.—J. P. O.

Manuring in Germany; Present position of the science of ——. M. Hoffmann. Bull. Agric. Intell. and Plant Diseases, 1914, **5**, 976—984.

EXPERIMENTS have been made regarding the temperature, concentration and duration of influence of the carbonic acid solution in soil. A regular relation was found to exist between the quantities present in the solution and those recovered in the crop. The results of the action of bacteria, yeasts and enzymes in bringing into solution the compounds of potassium and phosphoric acid are most readily investigated if the soil is previously steamed under pressure. Soils, of which the potash content rendered soluble by steaming amounts only to 5%, will benefit by a potash dressing, whereas if the amount reaches 8%, no potash is required. Soils with less than 4% of soluble phosphoric acid, will profit by a dressing of phosphates. A meadow requires manuring the more widely the content of the air-dried crop of hay differs from the standard of 2% K_2O, 0·7% P_2O_5 and 1% CaO. The ratio between the plant foods found in normal plants is about 100 N : 50 P_2O_5 : 150 K_2O : 80 CaO. The use of this ratio, in conjunction with the results of a soil analysis, gives a rough idea of the manure which a piece of land will require before the next crop is sown. Plants in glass houses flower better after applications of carbon dioxide (injected into the soil from a cylinder, or produced by the action of hydrochloric acid on marble), but it has not been shown that the same holds in the field. Trials have been made to determine whether home-produced manures can be replaced completely by commercial manures, but the results have not been favourable. A direct nutritive effect of sodium has been proved.—J. H. J.

Talbot slag. O. Dafert. Z. Landwirtschaft. Versuchsw. in Oesterreich, 1914, 301—302. Stahl u. Eisen, 1914, **34**, 1135.

SAMPLES of Talbot slag from an Austrian works contained: SiO_2, 8·86—10·04; FeO, 5·45—9·23; Fe_2O_3, 2·75—7·35; MnO, 3·50—6·46; Al_2O_3, 3·58—7·48; CaO, 45·70—50·42; MgO, 3·75—4·60; P_2O_5, 14·01—17·90; S, 0·22—0·88; SO_3, traces, up to 0·16%. The slag resembles Thomas slag and should be equally valuable as a fertiliser.—A. T. L.

Fish manure. Bull. Imp. Inst., 1914, **12**, 429—442.

THE methods and machinery employed for the manufacture of fertilisers from fish of various kinds, from fish waste, and from *Crustacea*, are briefly described, with estimates of the cost of installations. Analyses of fish meals used as cattle food and of different fish manures are given and the use is discussed.—R. G. P.

Seaweed from Zanzibar [for use as fertiliser]. Bull Imp. Inst., 1914, **12**, 351—352.

THE seaweed, which is plentiful on the north coast of Zanzibar Island, contained H_2O 20·7%, N 0·76%, ash (much sand) 30·3%, K_2O 0·55%, P_2O_5 0·11%. It was thus poorer in fertilising constituents than certain species of *Fucus* and *Laminaria*, but would be useful for manuring coconuts if potassium compounds were also applied. —R. G. P.

Agricultural experiments; Distribution of the overhead electrical discharge employed in recent ——. I. Jørgensen and J. H. Priestley. J. Agric. Sci., 1914, **6**, 337—348.

THE strength of the discharge from an overhead wire network at a high potential varies according to the mobility of the carriers of the electricity and the velocity of the wind. The discharge is not limited to the area under the wires, and an equipotential curve around such an area is irregular in form and extended in the direction towards which the wind blows. This is of importance, as control and electrified areas have usually been placed close together in field experiments. Descriptions are given of the distribution of the discharge under various weather conditions. The effect of the discharge upon plant growth may possibly be complicated by the presence of radio-active disintegration products. The maximum current density of the discharge in some experimental stations, where the apparatus is constructed after the pattern of the Agricultural Electric Discharge Co., is of the order 10^{-n} amp./cm^2. Methods are discussed by which the influence of the overhead discharge wires on control areas may be minimised.—J. H. L.

Alcohol in the manufacture of phosphoric acid and phosphates. Fox. *See* VII.

PATENTS.

Manures and fertilisers containing phosphate compounds ; Manufacture of ——. A. Dickson, Dublin. Eng. Pat. 18,999, Aug. 21, 1913.

SEWAGE sludge is mixed with insoluble phosphate, such as phosphate rock, and dried, preferably between 200° and 315° C., to convert the phosphate into the available form. About 3 cwt. of finely ground phosphate may be added to each ton of sludge containing 80% moisture. The lry product may be enriched by adding sulphate of potassium, sodium, or magnesium.—T. F. B.

Fertiliser and process of producing the same from rock minerals. J. Perino, Boston, Mass. U.S. Pat. 1,111,490, Sept. 22, 1914 ; date of appl., March 20, 1914.

FINELY-GROUND rock containing fertilising elements (*e.g.*, mixture of potash-bearing silicate rock and rock phos-hate) is disintegrated by incorporating with a salt of a trong mineral acid, capable of dissociating into its acid nd base below 800° C., and heating gradually to a high emperature, preferably in the presence of steam at tmospheric pressure. The product is treated with water, hereby it is cooled and hydrated and falls to a dry owder.—F. SODN.

eed grain ; Treatment of ——. C. E. de Wolf, London, and H. E. Fry, Dorchester. Eng. Pat. 22,151, Oct. 1, 1913.

EE U.S. Pat. 1,106,039 of 1914 ; this J., 1914, 938. The itric acid may be replaced by a solution of a fertiliser, ich as sodium nitrate or ammonium sulphate.—T. F. B.

XVII.—SUGARS ; STARCHES ; GUMS.

eet sugar production. E. R. Taylor. Chem. News, 1914, **110,** 209—210. (See also Courthope and Chadwin, this J., 1912, 451 ; Ling, this J., 1912, 452 ; Collins and Hall, this J., 1913, 929.)

N view of the very promising results obtained recently the cultivation of sugar beet in England, it should now e possible to establish the beet growing industry in this untry, since Germany and Austria together supplied 5% of our sugar in 1912. The soil is well suited and the eld per acre is in most cases as great as at Continental ntres and frequently greater. The land is enriched by e cultivation of beets, so that other rotation crops ield better results after it. A considerable portion of e English farming land which has gone out of cultivation om various causes, could profitably be put under beet. n important feature of the beet industry is the number by-products, viz., the pulp finds a ready market, the aves are an excellent cattle food and the saturation lime good fertiliser. In the United States the area under et has trebled in ten years, the yield per acre has nearly ubled and the price per ton of beets has risen by nearly 0%. The roots are grown on a contract basis, the farmer greeing with the factory to plant a certain acreage for given number of years.—J. H. L.

ugar] *Cane crushing ; Notes on* ——, *in the United Provinces, India.* G. Clarke, N. Hussain, S. C. Banerjee, and L. Shanker. Bull. 42, 1—12, Agric. Research Inst., Pusa, 1914.

PERIMENTS have been made at Patabgarh and Shakja-npur during the last three seasons in regard to the haviour of cane on crushing, quantity of cane crushed r hour and extraction. The cane was crushed simul-neously in five 3 roller bullock-driven mills with 8-inch llers, slightly over two tons of each variety of cane amined being used. The juice was weighed and its crose content determined, and the sucrose was also termined in samples of the bagasse withdrawn from each ll at intervals of one hour. With Reora of Benares, indigenous variety very popular in the eastern districts. l Ashy Mauritius, an imported variety, the average results were respectively: juice 61·3 and 74·0, with sucrose 9·6% and 15·4%, bagasse 38·7 and 26·0, with sucrose 5·4% and 6·4%, consequently extraction 73·8 and 87·2 per 100 of sugar in the cane. Results are given in detail for a great number of varieties of cane.—L. J. DE W.

Sulphur ovens ; Use of washers and coolers with —— [*in cane sugar manufacture*], *and* [*determination of*] *the sulphuric acid content of the oven gases.* H. Pellet. Bull. Soc. Chim. Maurice, **3,** 108—110 ; Intern. Sugar J., 1914, **16,** 465.

THE use of washers is unnecessary, since the few mgrms. of sulphuric acid that may be present in the oven gases combine with the organic salts in the juice to form sulphates, which have no inverting action upon sucrose. Coolers, however, must be used to prevent entrainment of sulphur, which might otherwise deposit in the gas exit pipes. To prevent trouble due to condensation of sulphuric acid, the cooler should be made of lead, or two coolers may be worked alternately, one being in use while the other is being cleaned. To determine the sulphuric acid content of the gases a known volume is passed through two wash-bottles, each containing 100 c.c. of recently boiled cold distilled water and 10 c.c. of concentrated hydrochloric acid, in which liquid sulphur dioxide is sparingly soluble. After passing say 10 litres of the gas, the contents of the bottles are transferred to separate beakers, and the sulphuric acid determined by precipitation with barium chloride in the customary manner. The amount of sulphuric acid found in the second wash-bottle (due to oxidation of sulphur dioxide) is deducted from that found in the first, the difference giving the sulphuric acid in the oven gases.
—J. P. O.

Solidified molasses ; Manufacture of —— [*Use for alcohol manufacture*]. H. C. Prinsen Geerligs. La. Planter, 1914, **53,** No. 11, 173—174.

SOLIDIFIED molasses is being made in considerable quantities in Java, and exported to British India for spirit manufacture. The molasses is treated with direct steam, and after separation of suspended impurities, is boiled in a vacuum pan in the ordinary way, concentration being continued until a small sample becomes as brittle as glass when dropped into cold water. A high and uniform vacuum must be maintained to avoid over-heating and decomposition, and boiling should be as short as possible, not lasting more than three hours. The concentrated mass is cooled rapidly, and run into bamboo baskets lined with palm mats, in which containers it may readily be transported.
—J. P. O.

Carbohydrates ; Methods of determination of ——. *III. Cupric-reducing power of the pentoses — xylose and arabinose.* A. J. Daish. J. Agric. Sci., 1914, **6,** 255—262. (See also Davis and Daish, this J., 1913, 1021.)

THE accompanying table gives divisors (obtained from "smoothed out" curves) for use in determining xylose and arabinose under the conditions of working described by Brown, Morris and Millar (this J., 1897, 165, 166). The two xylose preparations used gave $[\alpha]_{D}^{20} = +18·76$ ($c = 5·142$) and $+18·78°$ ($c = 5·0755$), and the two arabinose preparations $+102·14°$ ($c = 6·8064$) and $+102·33$ ($c = 4·669$). Both sugars were dried to constant weight at 96° C. *in vacuo* over phosphoric anhydride.

Starches ; Diverse nature of ——. C. Tanret. Comptes rend., 1914, **159**, 530—532. (See also this J., 1914, 607.)

Starches from 16 different plants were heated with water from 35° to 100° C. and the quantities of amylose dissolved at various temperatures were compared colorimetrically by means of iodine, after the liquids had been allowed to stand overnight to allow suspended matters to subside. Wide differences were observed in the quantities of amylose dissolved from different starches at the same temperature, and in the relative quantities dissolved at different temperatures. The solubility curves were neither regular nor similar to one another in form. There may be in each starch a mixture of homologous amyloses of different solubilities, or one principle in different stages of condensation.—J. H. L.

Equilibrium in the system : lead acetate, lead oxide, water. Jackson. *See* VII.

Use of sweet jowar (*sorghum sp.*) *as a source of commercial sugar or as fodder.* Annett. *See* XIXa.

Patent.

Maple-sugar evaporator. R. H. and H. K. Ober, Fort Jackson, N.Y. U.S. Pat. 1,112,380, Sept. 29, 1914 ; date of appl., June 28, 1912.

The evaporating pan is divided into a number of longitudinal parallel compartments ; the outer compartments communicate with the intermediate compartments at one end whilst the intermediate compartments communicate with each other at the opposite end. Longitudinal heating flues are fitted in the intermediate compartments. The syrup is supplied to a heating pan at one end, and then flows through the compartments of the evaporator, the rate of flow being controlled by a valve operated by a float fitted on the supply pipe.—W. P. S.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes of Aspergillus oryzæ and the application of its amyloclastic enzyme to the fermentation industry. J. Takamine. J. Ind. Eng. Chem., 1914, **6**, 824—828.

By using fungus acclimatised to an antiseptic (U.S. Pat. 1,054,626 ; this J., 1913, 444), it has become possible to prepare Taka-koji in a rotating drum and hence at a considerably lower cost than by the older process (this J., 1898, 118). A large iron cylinder which can be rotated at the rate of once per minute, has an inlet and outlet on opposite sides for air, drawn through by means of a suction fan, and is fitted with an independent central iron pipe provided with radial branches through which water or steam can be sprayed. The drum is charged with wheat bran, the necessary quantity of water and steam introduced, and the drum set in rotation. When the bran is thoroughly steamed, it is cooled to 45° C. by moist air, and an aqueous solution of an antiseptic and a suspension of spores of the fungus are successively introduced in the form of spray. After about 12 hours, the temperature begins to rise, and the drum is set in motion and a slow current of air drawn through. The temperature must not fall below 30° C., and from the 18th to the 24th hour, when the temperature tends to rise rapidly, the air current is increased so that it does not rise above 38°—40° C. The process is complete in 48 hours. The Taka-koji made in this way forms an efficient substitute for malt in alcoholic fermentation (see Ortved, this J., 1913, 708). The properties of Taka-diastase, separated from the Taka-koji, are also described. It possesses the great advantage over malt diastase as a medicinal agent of retaining its activity almost unchanged for several years.—A. S.

Beer yeast for industrial and therapeutic purposes. E. Carlinfanti. Annali Chim. Appl., 1914, **2**, 121—128.

In determining the activity of yeast by a fermentation test, considerably higher results are obtained if the carbon dioxide be removed continuously by a current of air during the test. Freshly prepared dried yeast shows a considerably lower fermenting power than fresh yeast in the first 12 hours of the test, but its activity subsequently increases. When dried yeast is kept, its fermenting power diminishes and may almost completely disappear. A number of commercial preparations of dried yeast for pharmaceutical use were examined. In all cases hardly any fermentation occurred in the first 12 hours, and the fermenting power was very low even after 24 hours.—A. S.

Yeasts : Supposed assimilation of sugars by —— *in the absence of fermentation.* W. A. Davis. Chem. World, 1914, **3**, 271—273.

Kahlbaum's "pure" maltose contains not only traces of nitrogenous matter (see Kluyver, this J., 1913, 803) but also 5—15% of dextrin and small quantities of dextrose, and all commercial preparations of pure maltose examined by the author have contained impurities. This fact explains many of the anomalous results obtained by Lindner's "*Kleingärmethode*" (see this J., 1910, 1221 ; 1911, 301, 1465), such as the assimilation of maltose by maltase-free yeasts which are incapable of fermenting it, and the greate assimilability of maltose as compared with dextrose and sucrose. Experiments with pure cultures of the maltase-free yeasts, *S. Marxianus*, *S. Exiguus* and *S. anomalus* showed that when incubated with solutions containin highly purified maltose and dextrose or sucrose, thes yeasts ferment every trace of the latter sugars, wherea the maltose can be quantitatively recovered even afte 3—6 weeks (cp. Davis and Daish, this J., 1913, 1024) The "*Kleingärmethode*" is a very imperfect means o investigating yeasts and many of the conclusions to whic it has given rise, where not already disproved, are highl improbable. Hayduck's nutrient solution (asparagin an salts) is not a suitable medium for all yeasts since som do not assimilate asparagin readily ; yeast water is a muc better source of nitrogen.—J. H. L.

Manufacture of solidified molasses. Prinsen-Geerlig *See* XVII.

Critical temperatures of solution, and haemolytic properties *alcohols.* Vandevelde. *See* XX.

Patent.

Yeast ; Process for eliminating bitterness from ——. P. Docherty, Burton-on-Trent. Eng. Pat. 10,774, May 1914.

Washed yeast is treated with a weak alkaline solutio *e.g.*, a solution containing about 7·5 oz. of ammoniu carbonate per cwt., then washed with water and allowe to remain for 12 hours in contact with blocks of wood cha coal.—W. P. S.

XIXa.—FOODS.

Milk ; The cryoscopic method for the detection of add water in ——. J. S. Maclaurin. Forty-Seventh Annu Report of the Dominion Laboratory, New Zealan 1914, 76—80.

Examination of 270 authenticated samples of milk, com prising morning and evening milks, milks from individu cows and the mixed milk of herds, showed that the freezi point of pure fresh milk does not rise above —0·545° C. fall below —0·565° C. ; the average freezing point m be taken as —0·550° C. The addition of water raises t freezing point to some intermediate point between—0·55 C. and 0° C., the rise being proportional to the amount water added. —W. P. S.

Milk ; Detection of added water in ——. J. W. Leath Analyst, 1914, **39**, 432.

The freezing point of the milks from 25 individual co varied from —0·529° to —0·577° C., whilst for the mix milks it ranged from —0·537° to —0·555° C. In the case of a milk freezing at —0·555° C., the addition of 5% and 10% of water raised this point to —0·519° C. and —0·490 C. respectively.—W. P. S.

Flour ; On the presence of sulphates in ——. R. A. Cripps and A. G. Wright. Analyst, 1914, 39, 429.

The quantity of sulphuric acid found in the ash of flours is very small (usually below 0·02% of the weight of the ash) owing to the fact that acid phosphates, the chief constituents of the ash of flour, decompose sulphates on ignition and cause the loss of the sulphuric acid. Larger quantities of sulphuric acid are found when the determination is made directly on the flour. One hundred grms. of flour are shaken for 1 hour with 1000 c.c. of 1% acetic acid, and allowed to stand for about 12 hours; 500 c.c. of the solution are then decanted, boiled after the addition of a small quantity of hydrochloric acid, nearly neutralised, the proteins precipitated with Almén's tannin reagent, the precipitate removed by filtration, and the sulphuric acid determined in the filtrate by precipitation with barium chloride. In this way, from 0·0069 to 0·0084% SO_3 was found in various flours; a whole-meal flour yielded 0·0103%.—W. P. S.

[*Sorghum Sp.*] *; Use of sweet jowar* —— *as a source of commercial sugar or as fodder and the variation in composition of the crop during growth.* H. E. Annett. Bull. No. 4, Agric. Research Inst., Pusa. (See also Bryan, this J., 1912, 696).

Saccharine sorghum was grown on experimental plots at Lyallpur and Gurdaspur in the Punjab. As a source of sugar the plant is not worth growing in India, for the high proportion of dextrose in the juice (cp. Bryan, *loc. cit.*) prevents the production of good crystalline gur, and the yield of sugar would be only about 1/3 of that from ordinary sugar cane crops. The plant appears valuable as a source of fodder. It grows fairly quickly (within three months), and from one of the experimental plots 13 tons of total green matter were obtained per acre. It should be cut when the seed is at the thin milk stage (see *loc. cit.*), the total weight of the plant and the nutritive value being then at their maximum and the total sugar almost at its maximum. —J. H. L.

Hydrocyanic acid in feeding-stuffs ; Determination of ——*, and its occurrence in millet and Guinea corn.* J. R. Furlong. Analyst, 1914, 39, 430—432.

One hundred grms. of the ground material are extracted with 90% alcohol for 3 hours in a Soxhlet apparatus, and the extract, after expelling the alcohol, is distilled with 150 c.c. of 10% sulphuric acid, the distillate being collected in 5 c.c. of 10% potassium hydroxide solution. At the end of 1 hour, the receiver is changed, water is added to the distillation flask, and the distillation continued. These operations are repeated until evolution of hydrocyanic acid ceases. The distillate is concentrated to 15 c.c., boiled for 10 mins., after the addition of 1 c.c. of a 20% solution of ferrous sulphate containing also 1% of ferric chloride, cooled, acidified with hydrochloric acid, and 10 c.c. of glycerol added. After standing for about 18 hours, the mixture is transferred to a graduated cylinder, diluted to 50 c.c. with water, and the blue coloration compared in tubes of 1 in. diam. with standards prepared rom known quantities of hydrocyanic acid. When the amount of hydrocyanic acid present is not less than 0·001 grm. the standards may be made up directly, but with smaller quantities it is necessary to dilute to 150 c.c. and hen concentrate as in the preparation of the solution rom the plant material. From determinations of hydrocyanic acid in millet and Guinea corn plants of various ages, t was found that all the young plants contained a cyanogenetic glucoside, whilst the full grown plants were free rom this substance. In the case of Guinea corn, the yield of hydrocyanic acid reached a maximum (0·01%) in the 12 in. plants, and decreased as growth proceeded. With millet, the maximum amount of hydrocyanic acid (0·045%) was found in the 24-in. plants.—W. P. S.

Changes in official methods of analysis of cottonseed products. *See* XII.

Determination of carbohydrates. III. Cupric reducing power of xylose and arabinose. Daish. *See* XVII.

Patents.

Flour and flour stock ; Treatment of —— *and appliances therefor.* B. I. Levin, Manchester. Eng. Pats. 20,627, Sept. 12, and 22,366, Oct. 4, 1913.

The material is fed uniformly on to a rotating roller, travelling belt, or the like, which is maintained in a moist condition, and the product is removed by a scraper. Moisture may be supplied by means of a wick and the material may be removed from the roller by a rotary brush which also ensures intimate contact between the roller and the material.—F. Sodn.

Cream ; Method or process of homogenizing. H. N. Brawner, jun., Washington, D.C. U.S. Pat. 1,112,594, Oct. 6, 1914 ; date of appl., Aug. 28, 1912.

Cream is heated, submitted twice to a process for rendering it homogeneous, and then cooled.—W. P. S.

Food preparations or extracts ; Manufacture of ——. F. Krause, Steglitz, Germany. U.S. Pat. 1,113,021, Oct. 6, 1914. Date of appl., Jan. 24, 1914.

See Eng. Pat. 541 of 1914 ; this J., 1914, 937.—T. F. B.

Apparatus for making lard substitute [*hydrogenised oil*]. U.S. Pat. 1,113,151. *See* XII.

XIXb.—WATER PURIFICATION ; SANITATION.

Water ; Action of protozoa in the purification of stored ——. P. T. Müller. Arch. Hyg., 1912, 75, 321—352 ; Wasser u. Gas, 1914, 4, 208.

During the storage of water, the number of "foreign" bacteria present decreases, whilst the ordinary water bacteria are not affected. This is due to the activity of the protozoa. The disappearance of the bacteria is accompanied by a decided increase in the protozoa and infusoria, and this increase is proportional to the decrease of the bacteria. When the development of the protozoa is inhibited by the addition of potassium cyanide and saponin, the bacteria are no longer destroyed.—W. P. S.

Water purification by ozone—with report of the Ann Arbor plant. R. W. Pryer. J. Ind. Eng. Chem., 1914, 6, 797—800.

A brief description of the installation at Ann Arbor, Mich., U.S.A. The ozonisers are very similar to the Siemens-De Frise type, but an outer aluminium pole is used, mica tubes instead of glass and no water jacket for cooling. The filtered water is treated in wells 8—9 ft. deep, the ozonised air (containing on the average, 0·5 grm. of ozone per cb. metre) being forced upwards under a pressure of 5—8 lb., the ratio of ozonised air to water being about 1 : 2·2. During two years' working at no time was any considerable reduction of the number of bacteria observed ; usually the ozonised water contained more bacteria than before the treatment, and it was proved that *Bac. coli* was able to withstand the action of the ozonised air under the conditions described.—A. S.

Water ; The calcium hypochlorite treatment of ——. Klut. Mitt. K. Landesanst. f. Wasserhyg., 1913, 17, 94—116 ; Wasser u. Gas, 1914, 4, 420—421.

When water has been treated with a quantity of calcium hypochlorite equivalent to 0·67 mgrm. of available chlorine per litre, it has a distinct smell and taste of chlorine; the latter can be detected chemically, but may be removed by addition of an equivalent quantity of sodium thiosulphate. In the water so treated, the ammonia is oxidised to nitric acid, the chlorine is increased by 1 mgrm. per litre, and the oxygen absorption from permanganate is diminished. The treated water does not have any appreciable action on metal pipes, pumps, etc. Since commercial calcium hypochlorite varies somewhat in composition, especially as to its content in available chlorine, attention is directed to the use of liquid chlorine stored under pressure, for the purification of water supplies.—W. P. S.

Microbes suspended in water; Removal and separation of —— by means of a current of air. A. Trillat and M. Fouassier. Comptes rend., 1914, **158**, 518—520.

Microbes can be removed from water by means of a current of air to a greater or lesser degree according to their origin and age. Thus whilst *B. prodigiosus* was readily removed, *B. subtilis* under similar conditions was not carried along by the air, and between these extremes *B. coli* and the typhoid bacillus were partially removed. Experiments showed the possibility of a separation of *B. prodigiosus* and *B. subtilis* suspended in the same medium, the former alone being removed. In experiments with *B. proteus* a four months old culture was more readily carried over than a young 18 hour culture. The dimensions of the microbes and their capability for being moistened are the determining factors in their removal from the aqueous suspension.—G. F. M.

Water bacteria; The decomposing power of —— and a new method for the examination of water. W. Spät. Arch. Hyg., 1911, **74**, 237—288; Wasser u. Gas, 1914, **4**, 208.

The quantity of ammonia formed when water is incubated in a suitable medium affords some evidence of the purity of the sample. The decomposition is not always proportional to the number of bacteria present, since ordinary water bacteria, *B. coli*, and pathogenic organisms generally yield only small quantities of ammonia. When, however, the water contains soil bacteria due to contamination by surface drainage, large quantities of ammonia are produced. The samples of water need not be packed in ice during transit as the decomposing power of the bacteria is not affected by storage.—W. P. S.

Water; Rapid method for the bacteriological examination of —— and its use in the control of water supplies and filters. P. T. Muller. Arch. Hyg., 1912, **75**, 189—223; Wasser u. Gas, 1914, **4**, 186.

Ferric hydroxychloride is added to the water, the mixture is centrifuged, and the bacteria are counted, under the microscope, in a definite quantity of the sediment. The method yields results which agree with those obtained by the usual plate-culture methods.—W. P. S.

Nitric acid in water; Preparation of the hydro-strychnine reagent used for the colorimetric determination of ——. Denigès. Bull. Soc. Pharm., Bordeaux, 1914. Ann. Chim. Analyt., 1914, **19**, 221—222. (See this J., 1911, 827.)

In preparing the reagent the zinc used should be chemically pure, or if impure, it should be amalgamated, as follows: 50 grms. of zinc foil are covered with 50 c.c. of water and 20 c.c. of pure hydrochloric acid (sp. gr. 1·18), shaken, and 10 c.c. of a saturated solution of mercuric chloride added; the mixture is shaken for 2 mins., the liquid poured off and the foil washed by decantation, dried with filter paper and then in the air. The reagent should only be prepared when required. The end point of the reaction is only definite after immersion in a boiling water bath for a few minutes. The test is carried out by diluting 5 c.c. of the water to be examined, ten or more times if necessary, adding 0·3 c.c. of the reagent and mixing; then adding 2·5 c.c. of pure sulphuric acid and heating in a boiling water bath for 5 mins. The red colour produced, if nitrate is present, is compared with that given by a solution of potassium nitrate of known strength.—J. H. J.

Deposits in cast-iron and similar water mains. O. Casagrandi and R. Binaghi. Wasser u. Gas., 1914, **4**, 438.

The water supply of Cagliari, Sardinia, is conducted through iron pipes having a total length of about 18 km.; these pipes become choked periodically with a deposit. A similar deposit is formed in the aqueduct of Sinnai. The freshly formed deposit was found to be free from organisms, whilst the older deposits contained *Cladotrix aeracea*; the same growth took place both in iron and steel pipes. The formation of the deposit is affected by three factors, namely, the presence of carbon and silicon in the iron, the structure of the iron, and the character of the water; the chief factor, however, is the presence of dissolved oxygen in the water.—W. P. S.

Water; Preparation of distilled ——. Basladeau. Münchener med. Woch., 1913, 1601; Wasser u. Gas. 1914, **4**, 341—342.

Attention is directed to the importance of using pure distilled water in the preparation of solutions for subcutaneous injections. Ordinary distilled water frequently contains traces of heavy metals, iron, zinc, and alkalis derived either from the condenser or from the storage vessels, and the presence of these impurities has been noticed to have a distinct biological and physiological effect. For the preparation of pure water a platinum or silica condenser is preferable, but satisfactory results may also be obtained by the use of a condenser of Jena glass. The water must be protected from atmospheric impurities.—W. P. S.

Sewage treatment. R. Hering. J. Franklin Inst., 1914, **178**, 417—433.

Treatment is dependent upon the physical condition of the sewage and whether there is much organic matter in solution. In modern methods of treatment, use is made of those anaerobic bacteria which decompose the sewage without offence. One form of tank for this purpose is the Hampton tank as modified by Imhoff of Emscher. The tank consists of two side portions through which the sewage flows, at a reduced rate, and the solids settle out and pass through slots into a central chamber, which has no direct water outlet, and in which fat or light matter rises up a shaft and is skimmed off. The sludge accumulates at the bottom of the central chamber, and when the sulphur bacteria in it have died off it has no odour. This process of loss of odour takes 3—5 months, after which the sludge is removed automatically. It drains readily in a week, when it is in a fit condition for removal.—J. H. J.

Action of metals on water. Jorissen. *See* X.

Patent.

Air; Process of regenerating [exhaled] ——. H. R. Carveth, Niagara Falls, N.Y., Assignor to The Roessler and Hasslacher Chem. Co., New York. U.S. Pat. 1,111,055, Sept. 22, 1914; date of appl., Aug. 15, 1911.

The air is passed, in a closed circuit, over a series of masses of a regenerating agent, *e.g.*, an alkali peroxide, mixture of alkali peroxides, or mixture of alkali and alkaline-earth peroxides, and a hydrating agent, arranged alternately. —F. Sodn.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine in poppy capsules; Formation and yield of ——. G. Mossler. Pharm. Post, 1914 [53]; Pharm. Zeit., 1914, **59**, 600; Pharm. J., 1914, **93**, 525.

To improve the output of opium, and to elucidate the conditions of the formation of morphine in poppy-capsule latex, the following tests were made: An equal number, 250, poppy capsules, were treated as follows:—(1) After cutting off from the stem, dried in the air. (2) Heated for half an hour in alcohol vapour, under pressure, at 80°—83° C. (3) Crushed, while fresh, in a mortar, and air-dried. (4) Scratched, the exuded latex taken up on cotton-wool; the capsules were then cut off and air-dried together with the juice-soaked wool. (5) The same, except that the wool containing the latex and the capsules were sterilised with alcohol. (6) Capsules allowed to ripen in the ordinary manner. The amount of morphine and allied alkaloids in the material thus prepared was then determined, and, for comparison, calculated into the yield from the material dried at 100° C. In the case of the latex absorbed on wool, the average yield of extractive was found from a given number of capsules, and its alkaloidal value referred to the same source. The whole air-dried capsules gave 0·1369% of morphine, and 0·0605% of allied alkaloids; the whole sterilised capsules, 0·1301% of morphine, and 0·041% of other alkaloids; the crushed capsules, 0·0386 and 0·01443%; the scratched air-dried capsules, 0·12442 and 0·1129; the opium on the wool from the above, 0·1877 and 0·1620; the capsules and opium on the wool together, 0·3121 and 0·2991; the scratched capsules sterilised, 0·1147 and 0·0429; the opium on wool sterilised, 0·153 and 0·1293; the above capsules and opium on wool sterilised together, 0·2677 and 0·15825; the ripe capsules, 0·05327 and 0·01737%, respectively. It is evident that sterilisation with alcohol vapour causes no increase in the amount of morphine. After the exudation of the latex following scarification of the capsules, a notable quantity of morphine remains. The low yield of alkaloids obtained from the crushed capsules is noteworthy. From the point of view of the morphine output, it is evident that the capsules, as well as the opium derived from them, are valuable, and should be worked up.

Nicotine from waste tobacco plants; Improved yield of ——. E. Chuard and R. Mellet. Schweiz. Apoth. Zeit., 1914, **52**, 424, and Pharm. J., 1914, Oct. 24, 561.

At present, in Switzerland, when waste tobacco plants are utilised for the manufacture of nicotine, this is done as soon as the crop of choice leaves has been harvested for tobacco manufacture. Investigation shows this to be a mistake. If the stripped stems with buds and shoots are left in the ground, and the soil is dressed with sodium nitrate, a second growth will take place. This will ensure a much larger yield of nicotine, amounting in the authors' experiments to an increase of 77%. It was found that when the plants were pulled up at once, the average yield of nicotine per plant was 0·725 grm. When they were allowed to grow again, the yield rose to 1·284 grm. per plant. The sodium nitrate used as manure does not act directly in increasing the nicotine content, but indirectly in stimulating growth during which the base is elaborated. Of the separate parts of the plants examined, the shoots and roots contain considerably more alkaloid than the stems. Considerable loss of nicotine occurs on drying the material.

Digitalinum verum. H. Kiliani. Arch. Pharm., 1914, **252**, 26—32.

Crude *Digitalinum verum* can be purified by dissolving pt. in 3 pts. of cold methyl alcohol and adding 6 pts. of water. After two days the white granules are filtered off, washed with 10% methyl alcohol, and dried *in vacuo* and the operation repeated till tests show that not more than % of the dry powder is dissolved by shaking with chloroform for an hour, and that the m. pt. is 212°—214° C. The mother liquors are concentrated at 35°—40° C., any granules which separate are removed, and the liquid finally evaporated to dryness *in vacuo*. The residue is dissolved in 4 pts. of 95% alcohol and 5 pts. of ether gradually added to precipitate the by-products. The clear liquid is concentrated to a syrup and mixed with pts. of 10% methyl alcohol. For hydrolysis, 1 pt. of *Digitalinum verum* is added to 10 pts. of a mixture of 00 c.c. of water, 100 c.c. of 96% alcohol and 20 c.c. of concentrated hydrochloric acid, and heated under a reflux condenser in a vigorously boiling water bath for an hour. After standing for 18—24 hrs. the crystals of digitaligenin are filtered off and washed first with 30% alcohol and then with water till all acid is removed. The alcoholic washings and the first water washing are extracted with chloroform which is dried by means of sodium sulphate, and evaporated. The residue is dissolved in 50% alcohol and sown with a crystal of digitaligenin. The product is dissolved in boiling 85% alcohol, the solution decolorised with animal charcoal, and the solid precipitated by the addition of water, when pure white needles are obtained, m. pt. 212°—213° C. The liquors left after extracting with chloroform are freed from acid by means of silver carbonate, evaporated to dryness *in vacuo*, and the syrup dissolved in 1 pt. of methyl alcohol. The solution is mixed with 1 pt. of absolute ether, and sown with a crystal of dextrose
—F. Shdn.

Hydroxymethylanthraquinones in rhubarb, senna and cascara; Determination of the free and combined ——. Daels. Bull. Acad. med. Belge, 1913, 350. Ann. Chim. Analyt., 1914, **19**, 177—179.

From 2 to 5 grms. of the powdered drug are treated in a flask, with 200 c.c. of chloroform, the whole weighed, and heated under a reflux condenser, for 15 mins. The chloroform solution of the free hydroxymethylanthraquinones is filtered off and the residue washed with chloroform. The insoluble residue is washed off the filter back into the flask and made up to the original weight with chloroform. After adding about 50 c.c. of 25% sulphuric acid the whole is weighed and heated on a water bath under a reflux condenser for 2½ hrs., the powder being kept below the surface of the liquid. When cool the weight is again made up with chloroform which is drawn off and 150 c.c. filtered, and shaken with 50 c.c. of 10% sodium bisulphite solution. The chloroform solution is then filtered through kieselguhr, washed with 100 c.c. of 1% hydrochloric acid, and 100 c.c. filtered into a tared flask, evaporated to small bulk and the residue, representing the combined hydroxymethylanthraquinones of the drug, dried at 60°—70° C. The chloroform solution of the free hydroxymethylanthraquinones is shaken out successively with quantities of 50 c.c. of 5% sodium hydroxide solution till it becomes colourless or slightly yellow. The united alkaline extracts are shaken out once with chloroform, diluted with an equal volume of water, filtered, acidified with hydrochloric acid, and shaken out three times with 25 c.c. of chloroform. The chloroform solution is filtered through kieselguhr into a tared flask and evaporated to dryness. Rhubarb contains 0·10 to 0·28% of free, and 3·18 to 5·53% of combined hydroxymethylanthraquinones. Senna contains 1·98 to 2·12% and cascara 1·32 to 1·44% of combined hydroxymethylanthraquinones.—F. Shdn.

Essential oil industry in Seychelles. Rept. Collector Customs Seychelles for 1913. Bull. Imp. Inst., 1914, **12**, 464—466.

This industry is increasing, and new distillation machinery has been installed. The oils exported are chiefly those from cinnamon and clove leaves and lemon grass. In 1912, 506 galls., value 7700 rupees (1 R. = 1s. 4d.), and in 1913, 924 galls., value 16,482 rupees, of essential oils were exported to France, Germany, and the United Kingdom.—R. G. P.

Essential oils of the new British Pharmacopœia. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 376—379.

The suggestions made by C. A. Hill and J. C. Umney as to the essential oils of the British Pharmacopœia have been nearly all adopted (see this J., 1910, 295). *Oleum pimentae* and *oleum pini* (*pumilionis*) have been omitted, the latter being replaced by *oleum abietis* (*oleum pini Sibiricae*, "oil of pine"). Ajowan, lemongrass and wintergreen oils have been included. Comments on the monographs are given and the principal standards, including the sp. gr., optical rotation, and refractive index at 25° C., are summarised in the following table.

Oleum.	Sp. gr.	Opt. rot.	Ref. ind. (25°).	Other standards.
Abietis	0·900—0·920	—32° to —42°	about 1·474	Esters as bornyl acetate 30—40%.
Ajowan	0·910—0·930	+ 1° to + 2°	—	Thymol at least 40%.
Anethi	0·910—0·915	+70° to +80°	1·483—1·488	Solubility 1 in 3 of 90% alcohol.
Anisi	0·975—0·990 $\left(\text{at } \frac{20^\circ}{15{\cdot}5^\circ}\right)$	— 2° to + 1°	1·552—1·558	80 per cent. distils between 225° and 235°. Congealing about 15·5°. Liquefying not below 17°.
Anthemidis	0 905—0·915	— 1° to + 3°	1·445	Solubility 1 in less than 1 of 90%alcohol.
Cadinum	about 0·990	—	—	Test for absence of pine tar.
Cajuputi	0·919—0·930	Not more than —4°	1·460—1·467	Cineol 45% (phosphoric acid process).
Carui	0·910—0·920	+75° to +82°	1·485—1·497	Not less than 50% distils above 200°.
Caryophylli	1·047—1·065	—	1·528—1·540	Eugenol 85% (soda process)
Cinnamomi	1·000—1·030	—0°·5 to —1°	1·565—1·580	Cinnamic aldehyde 55—65%.
Copaibæ	0·896—0·910	— 7° to —35°	1·494—1·500	Distils between 250° and 275°.
Coriandri	0·870—0·885	+ 8° to +14°	1·463—1·467	Solubitity 1 in 3 of 70% alcohol.
Cubebæ	0·910—0·930	—25° to —40°	1·486—1·500	60% distils between 250° and 280°.
Eucalypti	0·910—0·930	—10° to +10°	—	Cineol 55% (phosphoric acid process). Solubility 1 in 5 of 70% alcohol.
Gaultheriæ	1·180—1·187	0° to — 1° (25°)	1·537—1·539	Esters as methyl salicylate 99%. Solubility 1 in 6 of 70% alcohol at 25°.
Graminis citrati	0·880—0·905	— 3° to + 3°	—	Aldehydes 70% minimum.
Juniper	0·862—0·890 (increasing with age)	— 3° to —15°	1·472—1·488	Soluble in 4 vols. of equal volumes 90% and absolute alcohol, becoming less soluble with age.
Lavandulæ	0·883—0·900	— 3° to —10°	—	Esters 7—11% for English oil and not less than 30% for foreign oil. Solubility 1 in 4 vols. 70% alcohol.
Limonis	0·857—0·860	+58° to +64°	1·473—1·476	Citral not less than 4%.
Menthae piperitæ	0·900—0·920	—20° to —35°	—	Total menthol not less than 50%. Esters as menthyl acetate not less than 5%. Soluble in 4 vols. 70% alcohol.
Menthæ viridis	0·925—0·940	—30° to —50°	—	Solubility 1 in 3 vols. 90% alcohol.
Myristicæ	0·870—0·925	+13° to +30°	1·474—1·484	Solubility 1 in 3 vols. 90% alcohol. Not more than 5% residue when evaporated on a waterbath.
Rosæ	*0·854—0·862	— 2° to — 4°	1·456—1·465	Melting point at 20° to 23°.
Rosmarini	0·895—0·920	— 2° to +15°	1·463—1·473	Total alcohols as borneol not less than 10%. Esters as bornyl acetate not less than 1·8%. Solubility 1 in 5 to 10 vols of equal parts 90% and 70% alcohol.
Santali	0·973—0·985	—13° to —21°	1·498—1·508	Total alcohols as santalol not less than 90%. Solubility 1 in 6 vols. 70% alcohol at 20° C.
Sinapis volatile	1·014—1·025	—	—	Distils between 148° and 156°. Allyl iso-thiocyanate not less than 92 grms in 100 c.c.
Terebinthinæ rectificatum	0·860—0·870	—	1·465—1·480	Distils almost entirely between 156° and 280°, leaving no appreciable residue.

* At $\frac{30^\circ}{15^\circ{\cdot}5}$

F. Shdn.

Oils of the Coniferae. II. The leaf and twig, and bark oils of white fir. A. W. Schorger. J. Ind. Eng. Chem. 1914, **6**, 809—810. (See also this J., 1914, 983.)

The white fir [*Abies concolor* (Gord.) Parry] grows on the mountain slopes from southern Oregon to Lower California and from Nevada, Utah and southern Colorado through Arizona and New Mexico. The oil from the leaves and twigs is usually greenish yellow in colour, with a green fluorescence, but two samples were lemon-yellow with no fluorescence. Six samples (yield 0·029—0·272, mean 0·128%) had the following characters: sp. gr. at 15° C., 0·8720—0·8777; n_D^{15}=1·4781—1·4796; a_D^{25}=—20·11° to —27·94°; acid value, 1·01—1·81; ester value, 12·52—27·34; ester value after acetylation, 47·84—55·51; esters (as bornyl acetate), 4·38—9·57 (mean 6·63)%; free alcohols,7·65—10·57 (9·39)%; total alcohols, 13·39—15·56 (14·59)%. The oil yielded the following fractions: 161°—165°, 15·5; 165°—170°, 42; 170°—180°, 18·5; 180°—195°, 3; 195°—240°, 13; and 240°—310° C. ("green oil"), 3%; and contained: furfural, trace; *l*-α-pinene, 12; *l*-camphene, 8; *l*-β-pinene, 42; *l*-phellandrene, 15; and free borneol, 9·5%. Two samples of the bark oil (yield 0·07 and 0·12% respectively) had the following characters: sp. gr. at 15° C., 0·8767, 0·8702; n_D^{15}=1·4833, 1·4809; a_D^{20}=—20·95°, —20·15°; acid value, 1·22, 0·87; ester value, 6·88, 6·43; ester value after acetylation, 23·34, 20·45; esters (as bornyl acetate), 2·41, 2·25%; free alcohols, 4·58, 3·90%; total alcohols, 6·48, 5·67%. The oil yielded the following fractions: 162·5°—170°, 65; 170°—180°, 14; 180°—192°, 8; 192°—250°, 4; 250°—300° C. ("green oil") 5%; and contained: furfural, trace; *l*-α-pinene, 9; *l*-β-pinene, 60; dipentene, 12—13; and free borneol 4·5%. The "green oil" appears to be similar to that obtained from the leaf oil of Douglas fir (see this J., 1914, 41).—A. S.

Oil of black sage. C. E. Burke and C. C. Scalione. J. Ind Eng. Chem., 1914, **6**, 804—806.

The oil was obtained by the steam-distillation of leave and twigs collected in February: yield 0·9%. It ha the sp. gr. 0·8979 at 15° C., specific optical rotation, 24·4 refractive index, 1·4729; acid value, 2·2; ester value 1·6; was insoluble in 70% alcohol and remained clear o cooling to —20° C. It was separated into its component by fractional distillation and was found to consist of pinene 6, cineol 30, dipentene, terpinene, etc. 25, thujone 8 camphor 25 and resinous material 5%. A sample of oi from material collected about 2 months later in the season contained 22·5% of cineol and 40% of camphor accordin to an analysis of the U.S. Bureau of Plant Industry (se Rabak, this J., 1912, 602).—A. S.

Oil of Artemesia arborescens, L. T. Jona. Annali Chim Appl., 1914, **2**, 63—68.

About 200 kilos. of the dried tops of the plants collecte shortly before flowering, yielded on distillation 1·14 kilos of a deep blue oil of sp. gr. 0·9458 at 15° C., which wa soluble in all proportions in 90% and in 10 vols. of 80% alcohol, and remained clear at —15° C. The oil containe neither sulphur nor nitrogen compounds. It had th saponification value, 29·3; ester value, 19·5, ester valu after acetylation, 50·0; and distilled chiefly between 185 and 310° C. at atmospheric pressure and between 90° an 210° C. at 33 mm. It contained a mixture of high boiling hydrocarbons; formic, acetic, isovaleric, pelargonic palmitic, and stearic acids, partly free and partly as esters about 13% of β-thujone, and 13·94% of alcohols, $C_{10}H_{18}$ (thujol and probably a small quantity of borneol), of whic 8·58% were in the free state and 5·36% as esters.—A. S.

Lantana Camara; An oil from the flowers and leaves of ——. D. D. Kanga. Arch. Pharm., 1914, **252**, 1—2.

The exotic *Lantana Camara* which is very abundant in southern India and is known as "Ghaneri," originally came from Central America. The oil obtained from either the dry or fresh flowers or the leaves had a strong persistent but pleasant odour of sage, the yield being 0·02% from the dry flowers and 0·2% from the leaves. The characters of the oil from the dried flowers were: sp. gr. 0·915 at 26°/15° C., refractive index 1·4987 at 26°—26·75° C., $a_D = +23{\cdot}9°$, saponification value 10, acetyl value 43·6. The oil from the leaves had the sp. gr. 0·92114 at 24°/24° C., $n_D^{27} = 1{\cdot}48933$, $a_D = +1{\cdot}96°$, and was obtained by the steam distillation of an alcoholic extract. (See also this J., 1909, 906.)—F. Shdn.

Perfumery industry; Applications of cold in the ——. C. de Chessin Cherchewsky. Z. angew. Chem., 1914, **27**, III., 42.

Artificial cold is employed in the purification of perfumes by chilling (*glaçage*), cold storage of plants and flowers, in the *enfleurage* process to keep the fat at the proper consistence, and for the condensers in the author's process of distilling flowers with a volatile solvent instead of with steam. In the manufacture of synthetic perfumes artificial cold is used in the extraction of certain constituents of essential oils (*e.g.* cineol from eucalyptus oil, safrol from camphor oil), to inhibit exothermic reactions in synthetic processes, for condensation of alcoholic distillates (heliotropin), in distillation *in vacuo* (methyl anthranilate), and in processes where ozone is used production of vanillin by treatment of eugenol solution with ozone).—C. A. M.

Perfumery and essences; Cuban trade in ——. Perfumery and Essent. Oil Rec., 1914, **5**, 374.

N 1912 the total Cuban imports under this heading amounted to 581,329 kilos. valued at approximately 120,000, and last year the imports totalled 683,179 kilos. worth approximately £125,000. France supplies about three-quarters of these goods, and Great Britain about one-fifth.—F. Shdn.

loves; Cultivation of —— *in Zanzibar.* F. C. McClellan. Bull. Imp. Inst., 1914, **12**, 415—420.

Details of methods of cultivation, fungoid and other pests, etc., are given. Clove cultivation forms the most important industry of Zanzibar and of the island of Pemba. The crop varies considerably from year to year, good crop being obtained once every three to five years. n 1912—13 the total yield was 135,386 frasilas (1 frasila= 5 lb.), of which 104,368 came from Pemba; in 1913—14 he total was 726,621 frasilas, 591,222 from Pemba. Annual market requirements are about 400,000 frasilas. Pemba has more than 2/3 of its total area under cloves, r about 35,000 to 49,000 acres. Large trees may yield 0 to 70 lb. of dry cloves, although the average yield is only about 3½ to 4 lb. per tree per annum. The cloves re picked by hand and dried in the sun; hot-air and ther driers have been tried but have been abandoned. —R. G. P.

hymol; Sources of ——. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 372—373. (See also this J., 1913, 378.)

HE only species of origanum yielding thymol exclusively *Origanum hirtum*, whilst oil from *O. Maru* yields carvacrol only. The oil obtained in the South of France from *Thymus vulgaris* contains both carvacrol and thymol. French thyme grown in Germany yields an oil containing carvacrol only, but German thyme and possibly Spanish thyme give thymol only. Essential oils from the following plants are possible sources of thymol: American horsemint, *Monarda punctata*; dittany, *Cunila mariana*; *Mosla japonica* (indigenous to Japan), and *Satureja thymbra* (a Spanish spice).—F. Shdn.

Cloves from Zanzibar. Bull. Imp. Inst., 1914, **12**, 337—340.

The following samples were examined. (A) Cloves from trees 8 to 9 years old; (B) Stems from (A); (C) Cloves picked just before buds turned pink, about 8 to 10 days before ready; trees about 45 years old; (D) Stems from (C); (E) Cloves picked when buds were pink, ready for picking; trees about 60 years old; (F) Cloves picked when in full flower; trees about 60 years old; (G) "Mother of cloves" (clove fruits) from trees about 60 years old.

	Value per lb. in London	Oil %	Eugenol in oil %
A	6d.	17·8	89
B	2½d.	5·9	—
C	7d.	19·2	88
D	2½d.	6·3	89
E	8d.	18·8	81
F	5d.	17·4	88
G	2½d.	6·5	90

The oil from (C) was the best, having an odour very similar to that of standard commercial clove oil. Next in order were (E), (A) and (F); the odour of oils from (B), (D) and (G) was decidedly inferior. All the samples of cloves, etc. were of good quality and readily saleable in London.—R. G. P.

Isoprene from commercial turpentines. C. H. Herty and J. O. Graham. J. Ind. Eng. Chem., 1914, **6**, 803—804.

The apparatus used was similar to the "isoprene lamp" of Harries and Gottlob (this J., 1911, 1074), except that the platinum wire was wound on a triangular pipe-stem to prevent short-circuiting between the coils: Each experiment was continued until condensation ceased in the receiver for the crude isoprene. The crude isoprene was fractionated, and the portion distilling at 35°—37° C. taken as pure isoprene. From commercial spirits of turpentine in 6 hours a yield of 5·5% (by vol.) of isoprene was obtained. The pinene fraction of turpentine distilling at 155°—156° C. gave in 8 hours, 8% of isoprene, whilst the higher-boiling fractions (from 169° C. upwards), containing dipentene, gave, in 2 hours, only 0·50%; hence the isoprene from spirits of turpentine must be derived from pinene rather than from dipentene as stated by Harries and Gottlob (*loc. cit.*). The volatile oil obtained from the oleoresin of *Pinus serotina*, by distilling under reduced pressure (1 mm.) and which is rich in limonene (see this J., 1908, 589), gave in 9 hours, a yield of 12% of isoprene. Pine oil obtained from resinous pine wood by steam distillation (see Teeple, this J., 1908, 346), gave in 6 hours, a yield of 4% of isoprene. No isoprene could be obtained from refined spruce pine turpentine obtained as a by-product in the manufacture of wood pulp from spruce pine, and consisting chiefly of cymene.—A. S.

Glycocoll; Metallic compounds of ——. A. Bernardi. Gaz. chim. ital., 1914, **44**, II., 257—260.

Mercury glycocollate, $(NH_2.CH_2.CO_2)_2Hg$ (see Ley and Kissel, Ber., 1899, **32**, 1357), when dissolved in water and treated with the calculated quantity of lime water, is converted into a mixture of the mercury and calcium compounds of glycocoll:

$$(NH_2.CH_2.CO_2)_2Hg + Ca(OH)_2 = \begin{matrix} CH_2.NH \\ \dot{C}O—O \end{matrix}\!\!>Hg + \begin{matrix} CH_2.NH \\ \dot{C}O—O \end{matrix}\!\!>Ca + 2H_2O.$$

The mercury compound melts with decomposition at 155° C., is almost insoluble in cold and slightly soluble in hot water, soluble in hot sodium carbonate solution and in cold hydrochloric acid and in ammonia. It is decomposed by potassium hydroxide with separation of yellow oxide of mercury. The calcium compound is a white crystalline substance, slightly soluble in cold and more soluble in hot water; it is precipitated from aqueous solution in an amorphous form by alcohol. In presence of water it is decomposed by carbon dioxide with formation of calcium carbonate and glycocoll. By the interaction of powdered mercuric sulphate and an aqueous solution of glycocoll, a double salt, $(NH_2.CH_2.CO_2)_2Hg,HgSO_4,3H_2O$, is obtained in white crystals, insoluble in the ordinary solvents. It decomposes at 102° C.—A. S.

Alanine and glycocoll; New reactions for ——. Chelle. Bull. Soc. pharm. Bordeaux, March, 1913. Ann. Chim. Analyt., 1914, **19**, 67—68.

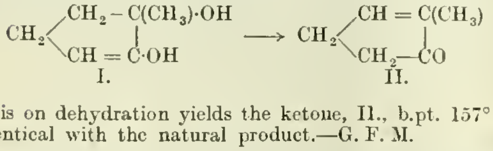
About 2—10 mgrms. of the substance are dissolved in 4 drops of water, 1 c.c. of glacial acetic acid and 0·5 c.c. of 5% sodium nitrite solution are added and the nitrous vapours boiled off. The liquid is boiled with 50—100 mgrms. of hydrazine sulphate and while still hot treated with 2 c.c. of concentrated sulphuric acid. After cooling 2 c.c. more of sulphuric acid are added. Separate portions tested with one drop of a 5% alcoholic solution of the reagent give the following colorations when alanine is present: guaiacol, red; codeine, lemon-yellow; *p*-cresol, orange. With glycocoll, guaiacol gives a reddish violet, codeine a violet, and *p*-cresol a green coloration, but the tints produced with the last two reagents are somewhat transitory.—F. Shdn.

Phenylalanine; Detection of ——. Chelle. Bull. Soc. pharm. Bordeaux, March, 1913. Ann. Chim. Analyt., 1914, **19**, 109.

Formaldehyde added to a solution of phenylalanine in concentrated sulphuric acid gives an orange coloration, rapidly turning brown. An alcoholic solution of paraldehyde added to a similar solution causes a lemon-yellow coloration to develop in a few minutes, followed by a green fluorescence in about an hour. One mgrm. of phenylalanine can be detected in this way.—F. Shdn.

Methylcyclopentenone; Synthesis of a ——. M. Godchot. Comptes rend., 1914, **158**, 506—508.

A cyclic ketone obtained by Looft (this J., 1893, 919) from wood tar, and by Bouveault (Bull. Soc. Chim., 1901, **25**, 435) from wood oils derived from the beech and oak was accorded by them the constitution of a Δ^5-1-methylcyclopentene-2-one. This is now confirmed by its synthesis from Dieckmann's cyclopentanedione-1.2 (Ber., 1897, **30**, 1470), by the action of magnesium methiodide with which it reacts in the ketone-alcohol form giving the glycol, I., b.pt. 79°—81° C. at 15 mm.; $n_D^{16} = 1{\cdot}4734$; sp. gr. at 16° C., 1·051.



I. II.

This on dehydration yields the ketone, II., b.pt. 157° C., identical with the natural product.—G. F. M.

Alcohols; Critical temperatures of solution, and hæmolytic properties of ——. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1914, **28**, 149—166.

The physiological hæmolytic method, and Crismer's method of critical temperatures of solution (this J., 1904, 451 and 1907, 32) have been applied to the distillates obtained by the fractionation of commercially pure methyl and isoamyl alcohols, and whilst the latter method was capable of differentiating between them, the hæmolytic process was not sufficiently sensitive for the purpose. From a study of the critical temperatures of solution of mixtures of methyl or isoamyl alcohols with ethyl alcohol, using beef suet, or coconut oil as solutes, the composition of mixtures possessing the same density can be determined, and further a series of alcohols having the same properties as Crismer's "absolute alcohol" (99·072%) can be prepared from less concentrated ethyl alcohol by introducing suitable quantities of isoamyl alcohol. Tables and curves are given from which the composition of alcoholic solutions whose critical temperatures of solution are appreciably raised or lowered can be very accurately determined.—G. F. M.

Tar, Guyot ——. N. Petkow. Z. öffentl. Chem., 1914, 20, 232—233.

Ordinary wood tar (*Pix liquida pini or betulae*) is heated on the water bath for three hours with 6—10% of sodium bicarbonate and two to four times its weight of water. When cold the mixture is decanted, filtered, perfumed and treated with 0·1% of codeine. Three samples were brownish-black and had the characters: sp. gr. 1·0224—1·0254; alkaline reaction; 3·176—4·15% of extract; 1·44—1·936% of ash, the alkalinity of the latter being equivalent to 17·6—19·4 c.c. of *N*/10 acid. They were miscible in all proportions with water and evolved carbon dioxide on acidifying. Tar water prepared from ordinary wood tar is lemon-yellow and acid in reaction, whilst that prepared from the Guyot tar is brownish-yellow and alkaline. As a pharmaceutical speciality Guyot tar is liable to a duty of 100 fr. per 100 kilos. on entry into Bulgaria.—F. Shdn.

Silver in collargol and liquids of animal origin; Determination of ——. P. W. Danckwortt. Arch. Pharm., 1914, **252**, 69—76.

The ash from about 1 grm. of the colloidal silver is warmed twice with 5 c.c. of 25% nitric acid, and the solution transferred to a 100 c.c. flask. The residue of silver chloride is dissolved in 30 c.c. of 10% ammonia, added to the acid solution, and the whole, which should now contain excess of ammonia, is made up to the mark. Standard potassium cyanide solution is added to an aliquot portion with a little potassium iodide as indicator, and the excess titrated back with *N*/10 silver nitrate solution. For smaller amounts, the ammoniacal solution may be treated with hydrogen sulphide solution, acidified with nitric acid and the silver determined colorimetrically. —F. Shdn.

Argentum colloidale; Simple method of valuing —— F. Lehmann. Arch. Pharm., 1914, **252**, 9—12.

About 0·2 grm. of the *Argentum colloidale* is mixed wit 10 c.c. of water and treated successively with 10 c.c of concentrated sulphuric acid and 2 grms. of finel powdered potassium permanganate in small portions After standing for 15 mins. the mixture is boiled, cooled diluted with 50 c.c. of water and excess of ferrous sulphat added. The silver is then titrated with *N*/10 thiocyanat solution.—F. Shdn.

Chemicals and drugs in Canada. Oil, Paint, and Dru Rep., Oct. 19, 1914. [T.R.]

At the present time Canada offers an excellent market fo almost all drugs and chemicals. There is already scarcity in many products, such as carbolic acid, citric oxalic, tartaric, and salicylic acids and their salts, glyceri quinol, menthol, morphine, codeine, castor oil, olive oi potassium chlorate and permanganate, shellac, sodiu benzoate, and santonin. Prices have in many case advanced from 200 to 900%. The National Drug au Chemical Co., which supplies a large part of the market depends on imported goods for many of its supplies, an will soon be unable to meet many of the demands.

Addendum.

Synthetic drugs, etc.

This J., 1914, 1028, l. 22 from top, add references a follow:—

See also Coblentz, this J., 1904, 93; and [illegible], thi J., 1910, 383.

Patents.

Sera for the cure of cancer ; Production of ——. A. P. L. van Langeraad, The Hague, Holland. Eng. Pat. 7978, March 30, 1914.

The animal which is to supply the serum (*e.g.*, a dog or rabbit) is subjected to a preliminary immunising treatment with the milk gland tissue of one or more "domestic" animals (cows, sheep, or goats), and after a few days' interval blood is drawn and the serum prepared in the usual manner.—T. F. B.

Arsenic-antimony compound and process of making same. A. Bertheim and P. Karrer, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,111,821, Sept. 29, 1914. Date of appl., Sept. 24, 1913.

Organic arsenic-antimony compounds are obtained by treating with a strong reducing agent a mixture of an aromatic arsinic acid and an antimony compound in solution. The products are insoluble in water but soluble in dilute hydrochloric acid or dilute caustic soda solution. (See also Eng. Pats. 17,533 and 19,778 of 1913 ; this J., 1913, 1030 ; 1914, 102.)—T. F. B.

Methyl chloride ; Process of manufacturing ——. B. S. Lacy, Perth Amboy, N.J., Assignor to Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,111,842, Sept. 29, 1914. Date of appl., July 7, 1913.

Methane is mixed with a larger amount of chlorine than is necessary theoretically to form methyl chloride, and the mixture is passed into a suitably heated reaction vessel made of quartz.—T. F. B.

Colloidal solutions of rare metals ; Process for preparing ——. H. Granert. Ger. Pat. 275,704, July 22, 1913.

Stable colloidal solutions of the rare metals are obtained by reducing solutions of the metallic salt with hydrazine hydrate or other reducing agent in presence of serum-albumin.—T. F. B.

Santalol compounds possessing sedative properties ; Preparation of ——. J. D. Riedel A.-G. Ger. Pat. 275,794, Aug. 14, 1913.

The esters of santalol with *a*-bromo derivatives of the higher fatty acids (such as valeric acid or diethylacetic acid) possess sedative and local anæsthetic properties. —T. F. B.

Process for extracting from woods their soluble contents. U.S. Pat. 1,112,359. *See* XIII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Aldehyde- and acetone-bisulphites of organic bases and their use as photographic developers. G. Pellizzari. Annali Chim. Appl., 1914, 2, 129—132.

The bisulphites of organic bases such as are used as photographic developers form addition compounds with aldehydes and acetone, which are stable when dry, readily soluble in water, and furnish a developing bath ready for use simply by treating their solutions with sodium carbonate, which decomposes them into their components. p-Aminophenol-acetonebisulphite,

$$HO.C_6H_4.NH_2.H_2SO_3.(CH_3)_2CO,$$

is obtained by suspending 100 grms of the base in 200 c.c. of water, passing in a current of sulphur dioxide and adding gradually 50 c.c. of acetone. When the solution is clear, a further 20 c.c. of acetone is added. The compound separates in minute glistening crystals. The corresponding compound of methyl-*p*-aminophenol (metol) is prepared in a similar manner.—A. S.

XXII.—EXPLOSIVES ; MATCHES.

Permissible explosives [United States] ; Supplementary list of ——. U.S. Bureau of Mines, October, 1914. [T.R.]

The following list contains the names of all permissible explosives tested by the Bureau of Mines between January 1 and August 1, 1914.

Brand	Class	Manufacturer.
Aetna coal powder No. 2	1a	Aetna Powder Co., Chicago, Ill.
Coal special Nos. 1-A and 1-L. F...	4	Keystone National Powder Co., Emporium, Pa.
Mine-ite No. 6-D	1a	Burton Powder Co., Pittsburgh, Pa.
Miners' Friend Nos. 2, 3, 4, 5, and 6	1a	Atlas Powder Co., Wilmington, Del.
Vigorite Nos. 2, 3, 4, and 5	4	Atlas Powder Co., Wilmington, Del.

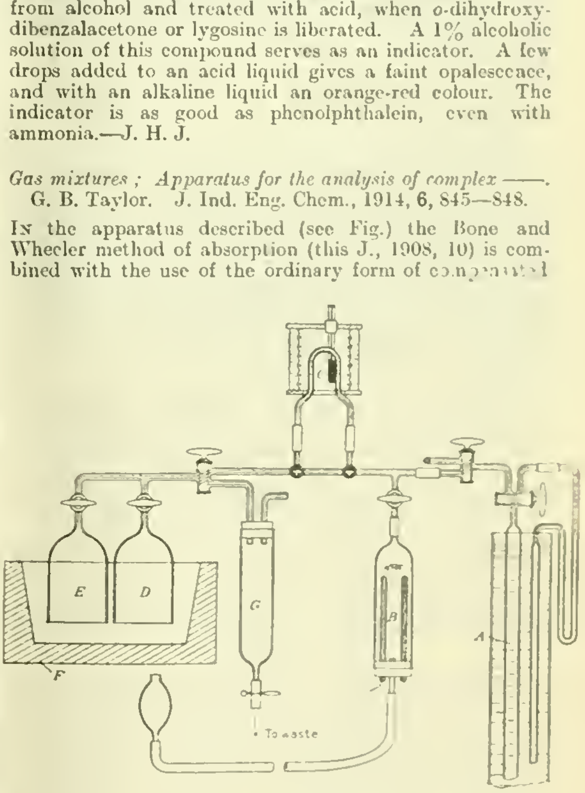
XXIII.—ANALYTICAL PROCESSES.

Indicator ; Dihydroxydibenzalacetone (lygosine) as a new ——. A. Ferencz. Pharm. Post, 1913, 521. Ann. Chim. Analyt., 1914, 19, 232.

Two mols. of salicylic aldehyde and 1 mol. of acetone are condensed in alcoholic solution by means of strong caustic soda. The substance which separates is recrystallised from alcohol and treated with acid, when *o*-dihydroxydibenzalacetone or lygosine is liberated. A 1% alcoholic solution of this compound serves as an indicator. A few drops added to an acid liquid gives a faint opalescence, and with an alkaline liquid an orange-red colour. The indicator is as good as phenolphthalein, even with ammonia.—J. H. J.

Gas mixtures ; Apparatus for the analysis of complex ——. G. B. Taylor. J. Ind. Eng. Chem., 1914, 6, 845—848.

In the apparatus described (see Fig.) the Bone and Wheeler method of absorption (this J., 1908, 10) is combined with the use of the ordinary form of compensated burette (A), an electrically heated, inverted U-tube, C, containing copper oxide for the combustion of hydrogen and carbon monoxide, and a slow-combustion pipette, B, for burning hydrocarbons. Small quantities of fresh absorbing reagents are used and the absorption vessels, D, E, dip into mercury in a wooden trough, F; the spent reagents are discharged through G. In the analysis of coal gas, for example, carbon dioxide is determined by absorption with caustic potash, then "illuminants" with fuming sulphuric acid, oxygen with alkaline pyrogallate, carbon monoxide



and hydrogen by combustion with copper oxide in the tube, C, at about 275° C., and paraffin hydrocarbons in the usual way by slow combustion in B.—A. S.

Sulphuric anhydride and chlorine; Chief cause of the loss of —— by incinerating substances containing these constituents. J. O'Sullivan. Analyst, 1914, **39,** 425—428.

Although chlorides are decomposed and chlorine is lost on incinerating substances containing chlorides, the quantities of calcium, potassium, and sodium sulphates which may be present, are not appreciably reduced. Magnesium sulphate undergoes decomposition on ignition unless a carbonate is present; in the absence of a carbonate, any magnesium sulphate present is converted entirely into magnesium oxide. When present in sufficient quantity in a substance containing chlorides, magnesium sulphate may cause the whole of the chlorine to be lost on ignition.—W. P. S.

Halogen determination in organic compounds. M. Busch and H. Stöve. Z. angew. Chem., 1914, **27,** III., 432.

The substance is dissolved in alcohol, dilute sodium hydroxide solution (containing about 0·2 grm. of $NaOH$) added, and the mixture introduced, with 1—2 grms. of calcium carbonate impregnated with palladium as catalyst (Paal and Karl, this J., 1913, 1089), into a vessel which is filled with hydrogen under pressure and mechanically shaken. Reduction is rapidly effected, and when complete, the solution is filtered and halogen estimated in the usual way. The palladium preparation may be used more than once.—F. Sodn.

Albumin; Colour reaction of —— with triformoxime. L. Lewin. Med. Klinik, 1913, 1122. Ann. Chim. Analyt., 1914, **19,** 281.

A solution of 0·10—0·15 grm. of triformoxime in 100 grms. of sulphuric acid gives a violet colour which is permanent with egg albumin, serum albumin, casein, peptone, papain and other proteins. At the point of contact of the two solutions, coagulation occurs. On shaking the violet colour spreads into the liquid. The violet solution has an absorption line $\lambda=536\ \mu\mu$. The reaction is very delicate; 0·2% albumin can be plainly detected. Selenious acid, arsenious acid and indole give the reaction. A solution of paraformaldehyde in sulphuric acid reacts as triformoxime, but less satisfactorily.—J. H. J.

Patents.

Temperature; Devices for measuring ——. M. L. Mellin, London. Eng. Pat. 5460, Sept. 4, 1913.

The movement of a body of mercury or of a Bourdon tube or similar device under the influence of change of temperature is transmitted to a resistance coil apparatus interposed in an electric circuit. The movement causes more or less resistance to be introduced into the circuit and the consequent variation of current is indicated by a galvanometer.—W. H. C.

Carbon dioxide gauge. E. A. Cunningham, Philadelphia, Pa. U.S. Pat. 1,111,565, Sept. 22, 1914; date of appl., Sept. 6, 1913.

Flue-gases are passed through a chamber containing a reagent for absorbing carbon dioxide. Normally the velocity of the gases is sufficiently high to prevent substantial absorption of carbon dioxide, but the flow is interrupted periodically and the fall in pressure due to absorption is indicated by a manometer and recorded automatically.—A. T. L.

Organic analysis ; Apparatus for use in elementary ——. H. Brach, Vienna. U.S. Pat. 1,112,432, Oct. 6, 1914. Date of appl., March 5, 1914.

See Ger. Pat. 263,680 of 1913 ; this J., 1913, 1035.—T.F.B.

Trade Report.

Competition with Germany and Austria-Hungary.

The Board of Trade has now issued a fourth list of articles which inquirers desire (A) to purchase, and (B) to sell. It may be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, London, E.C. The first three lists are referred to in this Journal, 1914, pp. 896, 945, and 1037.

Contraband of war.

A supplement to the London Gazette, dated Oct. 29th, contains a Proclamation making the following articles absolute contraband :—Projectiles, charges, and cartridges and their component parts. Powder and explosives specially prepared for use in war. Sulphuric acid. Armour plates. Hematite iron ore and hematite pig-iron. Iron pyrites. Nickel ore and nickel. Ferrochrome and chrome ore. Unwrought copper. Lead, pig, sheet, or pipe. Aluminium. Ferro-silicon. Mineral oils and motor spirit, except lubricating oils.

The following are made conditional contraband :—Foodstuffs. Forage and feeding stuffs for animals. Fuel, other than mineral oils. Lubricants. Powder and explosives not specially for use in war. Sulphur. Glycerin. Hides, pigskins, and leather.

France ; Exportation of certain articles prohibited from ——. Board of Trade J., Oct. 29, 1914.

The French "Journal Officiel" for the 15th October contains a Presidential Decree which prohibits the exportation and re-exportation of the undermentioned articles from France :—

Acetone : acetic acid and medicinal salts thereof ; carbolic acid ; salicylic acid ; methyl and ethyl alcohol ; anhydrous alumina ; aluminium ; antipyrin ; aspirin ; bauxite ; bismuth and bismuth salts ; bromine and bromides ; caffeine ; indiarubber, balata, gutta-percha, crude or melted down ; chloral ; chloroform ; chloride of lime ; scrap iron and steel ; wood creosote ; coal creosote ; cresol and derivatives thereof ; hydrogen peroxide ; sulphuric ether ; ferro-chrome ; ferro-nickel ; formol ; glycerin ; mineral tar ; iodine ; iodides ; iodoform ; iron filings and forge-scales ; filings and waste of copper, tin, zinc, pure or alloyed ; nickel (ore and metal), pure or alloyed ; sodium nitrite ; potassium, potash and potash salts ; amidopyrine ("*pyramidon*") ; caustic soda ; sulphonal ; theobromine ; trioxymethylene.

Exemptions from the prohibition may be accorded under conditions to be determined by the Ministers of War and Finance.

Netherlands contraband. Times, Nov. 2, 1914.

The latest lists of conditional contraband issued by the Netherlands Government contain the following :—On the French side.—Iron, steel, iron oxide, sulphate, and carbonate, copper, lead, nickel, ferrochrome, glycerin, hides, leather. On the German side.—Crude copper, block lead, lead plates, and lead tubes.

Chemicals and Dyestuffs Committee of the American Chemical Society. Oil, Paint, and Drug Rep., Oct. 19, 1914.

The New York Section of the American Chemical Society, on October 9, voted a committee to examine into the feasibility of expanding the manufacture of chemicals and dyestuffs in the United States and to report to the Section on November 6. This committee is composed of H. A. Metz, I. F. Stone, J. B. F. Herreshoff, David Jayne, J. M. Matthews, Allen Rogers, with B. C. Hesse, chairman. The committee will welcome any suggestions as to specific chemicals or dyestuffs that should be made in America. General suggestions will not be useful. Specific suggestions should be accompanied by a statement of the U.S. consumption, production, and prices, and may be sent to the chairman, B. C. Hesse, 90, William Street, New York City.

Books Received.

Glue and Glue Testing. By S. Rideal, D.Sc. (Lond.). Second Edition, revised and enlarged. Scott, Greenwood and Son, 8, Broadway, Ludgate, London, E.C 1914. Price 10s. 6d. net.

Volume, 8¾ by 5⅝ ins., containing 179 pages of subject matter, with 14 illustrations, and also an alphabetical index. The text is arranged under the following headings : I. Constitution and properties. II. Raw materials and manufacture. III. Uses of glue. IV. Gelatin. V. Glue testing. VI. Commercial aspects.

Methods of Quantitative Organic Analysis. By P. C. R. Kingscott, D.I.C., A.R.C.Sc., A.I.C., B.Sc. (Lond.), and R. S. G. Knight, D.I.C., A.R.C.Sc., A.I.C., B.Sc. (Lond.). Longmans, Green & Co., 39, Paternoster Row, London ; Fourth Avenue and 30th Street, New York ; Bombay, Calcutta, and Madras. 1914. Price 6s. 6d. net.

Volume (8¾ by 5⅝ ins.), containing 276 pages of subject matter, with 51 illustrations, and also alphabetical indexes of authors' names and of subjects. A table of International atomic weights, 1914, and a list of abbreviations, are followed by Chápters on : I. Determination of molecular weight by physical methods. II. Ultimate analysis. III. Estimation of typical groups. IV. Estimation of some compounds of technical importance. References to the original sources of the methods are given.

Saponi da Toeletta. Del C. Franchi. U. Hoepli, Milan. 1915. Price Lire 5.50.

Volume (6 by 4½ ins.) containing 467 pages of subject matter, including sections on : Raw materials for the manufacture of toilet soaps. Perfumes. Essential oils. Animal perfumes. Artificial perfumes. Perfumes for soaps. Colouring soaps. Filling (loading) soaps. Apparatus for the manufacture of toilet soaps. Processes of manufacture. Lanoline in toilet soaps. Transparent soaps. Soaps for the hair. Liquid soaps. Soap creams and powders. Soaps soluble in sea-water and hard water. There are 59 illustrations.

Catalysis in the Gas Industry. William Young Memorial Lecture delivered before the North British Association of Gas Managers, Glasgow, Sept. 3, 1914. By R. Lessing, Ph.D., F.C.S. Reprinted from Journal of Gas Lighting. W. King, 11, Bolt Court, Fleet Street, London, E.C.

The Chemical Examination of Water, Sewage, Foods, and other Substances. By J. E. Purvis, M.A., and T. R. Hodgson, M.A. Cambridge, at the University Press. 1914. Price 9s. net.

Volume (8¾ by 5⅝ ins) containing 215 pages of subject matter, and an alphabetical index. It forms one of the Cambridge Public Health Series, under the editorship of G. S. Graham-Smith, M.D., and J. E. Purvis, M.A. The text is subdivided as follows :—I. Water ; sewage ; and sewage effluents. II. Milk ; cream ; and condensed milk. III. Butter ; margarine ; lard ; dripping ; suet ; cheese ; cream cheese ; and edible oils. IV. Tea ; coffee ; chicory ; cocoa. V. Wheat flour : self-raising flour : baking powder ; bread ; rice ; starches. VI. Pepper ; cayenne ; mustard ; nutmeg ; cinnamon ; ginger. VII. Cane sugar ; golden syrup and treacle ; honey ; jam. VIII. Alcoholic beverages. IX. Vinegar ; lime and lemon juice. X. Poisonous metals in foods. XI. Preservatives ; Disinfectants. XII. Air ; coal gas ; other gases. XIII. Rag-flock. Urine. A bibliography is given on page 211.

The Electrical Conductivity and Ionization Constants of Organic Compounds. By H. Scudder, B.A., M.D., etc. Constable & Co., Ltd., 10, Orange Street, Leicester Square, London, W.C. 1914. Price 12s. net.

Volume (9½ by 6¼ ins.), containing 568 pages of subject matter. It is a bibliography of the periodical literature from 1889 to 1910 inclusive, including all important work before 1889 and corrected to the beginning of 1913. It gives numerical data for the ionization constants at all temperatures at which they have been measured; and some numerical data of the electrical conductivity. The text is classified as follows:—I. Abbreviations of words. II. Abbreviations of journal titles. III. Cyclic formulæ. III. Tables (compounds arranged alphabetically, with the ionization constant, some data of conductivity, and all bibliographical references given under each compound). IV. Formula index. V. List of authors (names arranged alphabetically). VI. Subject list. VII. Journal list. VIII. Addenda.

Van Nostrand's Chemical Annual, 1913. A Handbook of Useful Data for Analytical, Manufacturing, and Investigating, Chemists, and Chemical Students. Third Issue. Revised with addition of new tables and a section on Stoichiometry. Edited by John C. Olsen, M.A., Ph.D., Prof. of Analytical Chemistry, Polytechnic Institute, Brooklyn. Assistant Editor, Alfred Melhado, Brooklyn, N.Y. Constable & Co., Ltd., 10, Orange Street, Leicester Square, London, W.C. 1914. Price 12s. 6d.

Volume (8 by 5 ins.), containing frontispiece (Henri Moissan), 663 pages of subject matter, and an alphabetical index. The text is subdivided as follows:—I. General contents. II. Calculation of volumetric analyses. III. Calculation of gas analyses. IV. Physical constants of chemical compounds. V. Specific gravity tables. VI. Alcohol tables of the Bureau of Standards. VII. Equivalents of Weights and Measures. VIII. Thermochemistry. IX. Stoichiometry. X. New Books. List of the more important ones, published since July, 1909. American and English books. Foreign books, mostly German.

Nutrition. A Guide to Food and Dieting. By Chas. E. Sohn. Henry Kimpton, 263, High Holborn, London, W.C. 1914. Price 3s. 6d. net. Also 40 and 42, University Avenue, Glasgow.

Volume (7½ by 5 ins.), containing 246 pages of subject matter, seven illustrations, and an alphabetical index. The text is classified as follows:—I. General principles. II. Human body structurally regarded, chiefly with respect to the digestive system. III. Human body, chemically considered. IV. Classification of the constituents of foods. V. Digestion; assimilation; metabolism; respiration. VI. The body requirements. VII. Infant feeding. Proprietary infant foods. VIII. Meats, &c. IX. Dairy produce, eggs, &c. X. Bread and cereals generally. XI. Peas, beans, and other leguminous foods. XII. Starchy seeds, nuts, roots, &c. XIII. Oily seeds, nuts, &c. XIV. Fresh roots, &c. Fruits, green vegetables, mushrooms, algæ, &c. XVI. Sugars, jams, confectionery, pastry, &c. XVII. Food adjuncts, drinks, condiments. XVIII. Cooking. XIX. Seasons for foods.

The Purification of Gas by Heat. A Century's Progress and its Lessons. Lecture delivered by Charles Carpenter, D.Sc. M.Inst.C.E., before the Institution of Gas Engineers at Liverpool, June 17th, 1914. South Metropolitan Gas Company, 709, Old Kent Road, London, S.E. 1914.

Volume (8¾ by 5½ ins.), with 49 pages of subject matter, with 7 illustrations.

Thirty-Eighth Annual Report of His Majesty's Inspectors of Explosives; being their Annual Report for the year 1913. [Cd. 7650.] Wyman & Sons, Fetter Lane, E.C. Price 5½d.

This report deals with the work of H.M. Inspectors of Explosives under the Explosives Act of 1875 in connection with the manufacture, storage, packing and conveyance, and importation, etc. of explosives. The appendices to the Report include *inter alia* a list of explosives authorised for manufacture or importation, and details of the importation of explosives during 1913.

Bulletin of the Imperial Institute. Vol. XII. No. 3. July–September, 1914. Price 2s. 6d.

This issue of the Bulletin contains the results of investigations in connection with the quality of rubber from various sources, the economic products of the Zanzibar Protectorate. Sudan wheat, Burma pulse, and timbers from various countries. Information is also given respecting the utilisation of fish and marine animals as fertilisers, the tin resources of Australia, South Africa and Nigeria, the trade in palm kernels, etc.

Journal of the Society of Chemical Industry.
No. 22, Vol. XXXIII. NOVEMBER 30, 1914. No. 22, Vol. XXXIII

Official Notices.

APPOINTMENT OF NEW EDITOR.

The Council of the Society of Chemical Industry has pointed Mr. Tom F. Burton, B.Sc., of 63, Melbury Gar- West Wimbledon, S.W., to be Editor of the Society's Journal in place of Mr. Watson Smith, who has resigned. Mr. Burton will take up his duties at the new year.

BOARD OF TRADE BULLETINS.

Attention is directed to the notice inserted in this issue of the Journal, relative to the Bulletins on various industries which have recently been issued by the Board of Trade.

Journal and Patent Literature.

TENT SPECIFICATIONS may be obtained by post by remitting as follows :—
English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 05 c. each, as follows : Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.) ; Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL PLANT ; MACHINERY.

ler control ; Scientific ——. F. D. Harger. Amer. Brewer's Review, 1914, **28**, 391—392. J. Inst. Brew., 1914, **20**, 557—560.

minimise waste of the heating power of the fuel (see ble I.) continuous records of the temperature of the flue es and of their content of carbon dioxide should be de. The temperature should be the lowest possible th a good draught. An average of more than 7% CO_2 the flue gases is rarely attained without the constant of a carbon dioxide indicator. Carbon dioxide indi- rs are inexpensive to maintain (about 50 cents, or 1d. a month), their life is long, and they give trust- rthy results. The chief factor affecting the percentage carbon dioxide in the flue gases, is the air supply. excess of air over that theoretically required for the plete combustion of the fuel should be kept as low as sible. A draught gauge should be used, especially en working with forced draught. The thickness of the -bed, and the intervals between firing, especially with nd-fired boilers, also exert an influence. The thickness the fire-bed may vary with the draught available, the ty required of the boiler, and the class of fuel used, but eneral it should be as even as possible and free from les through which large volumes of air can enter. cumulations of soot in the tubes diminish the draught, l reduce the conductivity of the boiler plates ; a layer soot ⅛ in. thick will reduce the conductivity by about [illegible]

TABLE I.

g the percentage losses of coal corresponding to rious percentages of carbon dioxide in the flue gases. or different flue gas temperatures. The air entering he furnace is assumed to be at 60° *F.* (15·5° *C.*).

Boilers ; Serious corrosion of ——. A. Heinzelmann. Der Klein- u. Mittelbrauer, 1914, 238. Chem.-Techn. Rep., 1914, **38**, 376.

THE feed-water was very soft having a total hardness of only 3·5 degrees (German), the temporary hardness being only 1 degree. It contained 3 grms. SiO_2 and 3 grms. of nitrates per 100,000. Chlorides were present in very small amount. Boilers were worked at about 4 atmospheres pressure for many years without trouble, but when they were replaced by boilers working at 10 to 12 atmospheres, considerable corrosion was produced. After 2 months a hard crust, 6 mm. thick, had formed, and the water blown off was found to be strongly acid. The crust contained 80% Fe_2O_3 and 6% of alkali silicates. On the surface was a layer, 1 mm. thick, of calcium sulphate. The action was due to the decomposition under pressure of the chlorides and nitrates by the silicic acid. The liberated mineral acids attacked the iron, and the resulting salts becoming hydrolysed, a progressive rusting of the boiler took place. The trouble was overcome by adding sufficient sodium hydroxide to the feed water to keep the water in the boilers alkaline to phenolphthalein. This reaction between silicic acid and nitrates in boilers is considered to occur only at a pressure of nearly 10 atmospheres.

—T. St.

Lubrication with oils and with colloidal graphite. C. F. Mabery. J. Ind. Eng. Chem., 1913, **5**, 717—723.

COMPARATIVE tests were made under varying conditions in a Carpenter's machine (this J., 1910, 614) fitted with hard Babbitt metal bearings, run at a speed of 450 revolutions per min., and at a pressure of 200 lb. per sq. in. When the bearings were lubricated with one of the best motor lubricants (8 drops per min.), for 2 hours, and the supply then stopped, the oil film broke in 17 mins., whereas when the oil contained 0·35% of colloidal graphite, an extremely low and even coefficient of friction continued unchanged for 5 hours after lubrication was stopped. Oil containing respectively, 0·1% and 0·5% colloidal graphite did not give satisfactory results. When once established, a suitable surface could be maintained with a smaller proportion of graphite in the oil or a reduced quantity of oil containing the normal proportion. The same lubricating effect was obtained by the use of 1/16th of the quantity of oil required in the absence of colloidal graphite. In one experiment the pressure was supported for nearly 10 hours without the addition of fresh lubricant. This property of colloidal graphite is attributed to its saturating the metallic surfaces to form a "graphoil" surface in contradistinction to the film formed by oil. In all cases the temperature increased with the duration of the test up to a constant value not exceeding 65° F. (18° C.).

In general, the lower the friction coefficient, the lower the temperature. The advantages of the use of colloidal graphite for motor car engines are that it forms a graphoid surface on the bearings, which wears indefinitely, that it eliminates any chance of heating through irregular supply of the lubricant, and that it affords greater protection than an oil-film against sudden variations of strain on the bearings.—C. A. M.

Explosibility of mixtures of air and ammonia (Refrigerators). Schlumberger and Piotrowski. *See* VII.

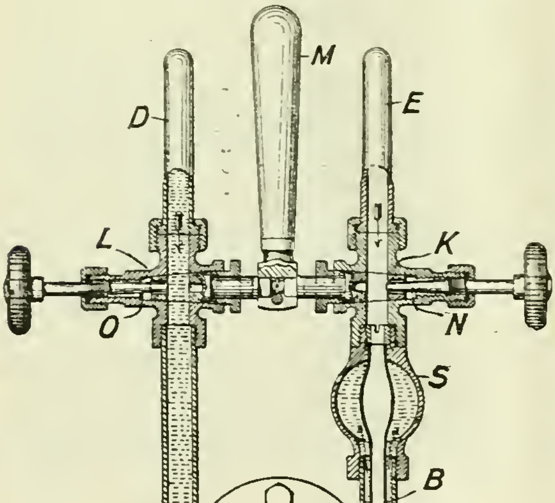
PATENTS.

Discharging compressed gases from storage vessels. J. B. Spurge, London. Eng. Pat. 22,032, Sept. 30, 1913.

To obtain a more regular flow from a cylinder of compressed or liquefied gas a heating coil is interposed between the cylinder and the expansion valve, and to keep back particles of liquid an intermediate vessel is interposed between the cylinder and the heating coil.—W. H. C.

Heating and cooling fluids; Apparatus for ——. W. Adams, Manchester. Eng. Pat. 27,499, Nov. 29, 1913.

A DOUBLE coil is placed in a casing, *U*, and surrounded with non-conducting packing. The liquid to be heated (or cooled) enters through the branch, *D*, passes through the annular space, *C*, between the pipes, to the globular expansion, *S*, and is discharged through a lateral branc not shown. The heating (or cooling) agent ente through the branch, *E*, passes through the inner pipe, . and is discharged through a branch which passes from t lower end, *G*, through the side or bottom of the casin The flow of liquid and heating (or cooling) agent is regulat by the two plug-cocks, *K*, *L*, coupled together and operat by the handle, *M*. Two pin-valves, *N*, *O*, are provid to adjust independently the quantity of liquid flowi through each of the plug-cocks.—W. H. C.



Briquetting-machines. C. Korte, Leeds. Eng. Pa 22,277, Oct. 3, 1913.

THE briquetting press is operated mechanically by a syste of lever devices so arranged that when the desired pressu has been attained, the action of the levers, etc., is aut matically stopped and reversed.—W. H. C.

Steam boilers, surface condensers and the like; Means f preventing formation of hard scale in —— and f removing such scale. G. C. Jones, London. Eng. Pa 22,767, Oct. 9, 1913.

IN using the process described in Eng. Pat. 19,637 1911, in which a current of electricity is passed betwe insulated anodes immersed in the water in the boil and that portion of the boiler which is in contact with t water, the prevention of scale is only effective when t amount of alkali chloride present in the water is equivale to the amount of calcium sulphate present. The cla is for adding a quantity not exceeding 1% of alkali chlori to the water.—W. H. C.

Steam boilers; Prevention of pitting and corrosion in — C. Haythorpe, London. Eng. Pat. 25,893, Nov. 12, 19

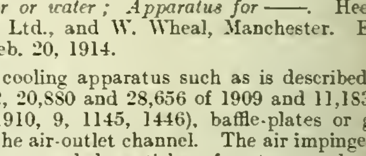
GRAPHITE plugs are inserted into the carbon plates compound zinc-carbon elements which are in meta connection with the boiler shell below the water li A fine deposit of graphite is formed on the boiler pla that come in contact with the heated water.—W. H. C.

Cooling air or water; Apparatus for ——. Heenan a Froude, Ltd., and W. Wheal, Manchester. Eng. P 4369, Feb. 20, 1914.

IN rotary cooling apparatus such as is described in E Pats. 6452, 20,880 and 28,656 of 1909 and 11,183 of 1 (this J., 1910, 9, 1145, 1446), baffle-plates or grids placed in the air-outlet channel. The air impinges agai these and suspended particles of water are deposited —W. H. C

Still. J. A. Ullman, New York. U.S. Pat. 1,113,5 Oct. 13, 1914; date of appl., Dec. 23, 1913.

THE side of the still is formed with a flange, 10, projecti inwards and having on its upper surface a groove, into which the flange, 6, of the still bottom, fits. T joint is made tight by means of angle pieces and bo 13.—W. H. C.

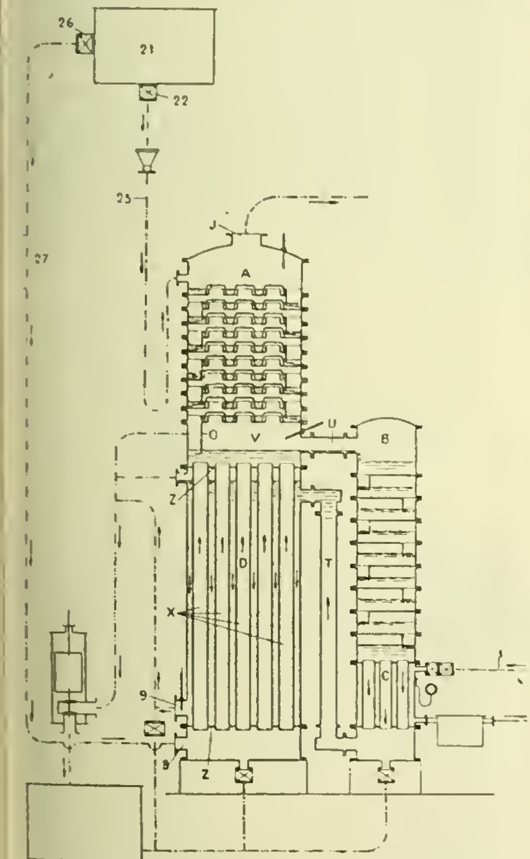


Refrigerating apparatus ; Condensers for ammonia gas ——. J. Dwyer, Montclair, N.J., U.S.A. Eng. Pat. 25,585, Nov. 8, 1913. Under Int. Conv., Dec. 30, 1912.

Groups of "trombone" coils disposed vertically and connected above and below with suitable headers, are arranged in a horizontal series, the bottom header of one group being connected with the top header of the next. The number of coils in each group and hence the condensing capacity is decreased from the inlet to the outlet of the series.—W. H. C.

Stills for the dissociation of chemical solutions by heat ; Continuous ——. R. Fabry, Sheffield. Eng. Pat. 337, Jan. 6, 1914.

The solution to be dissociated, *e.g.* crude ammoniacal liquor, sodium bicarbonate solution, etc., passes from the tank, 21, in regulated quantity, through the cock, 22, nd the pipe, 25, into the upper portion of the dephlegnator, A, where it serves to cool and condense the water apour accompanying the dissociated gases. Another egulated portion of the cold liquid is fed through the ock, 26, and pipe, 27, into the bottom of the tubular reheater, D, through the opening, 8; rises through the ubes, X, and mixes in the chamber, V, with the liquor lowing down the dephlegmator, A. The hot mixed iquid then overflows by the pipe, U, into the dissociator, B, lown which it flows to the tubular superheater, C, where t is heated by steam introduced through the pipe, 1. he liquor is completely dissociated in the vessel, B, nd the spent residue rises through the pipe, T, flows own the pipes, Z, of the preheater, D, parting with its heat o the incoming liquor, and is discharged through the pipe, . By suitably apportioning the flow of liquor between he two directions a nearly pure and dry gas is discharged hrough J, and the liquid is at the same time completely issociated with a minimum amount of steam.—W. H. C.



Distilling apparatus. A. G. Waterhouse, Assignor to Atlas Still Mfg. Co., New York. U.S. Pat. 1,113,521, Oct. 13, 1914 ; date of appl., Oct. 31, 1910.

The supply of liquid to a still is regulated by a valve which is operated by means of a thermal "actuator" (thermostat) placed in the still.—W. H. C.

Centrifugal machine actuated by fluid pressure. A. F. Dunsmore, Glasgow. Eng. Pat. 12,505, May 21, 1914.

The supply of motive fluid is regulated by a spring-controlled valve operated by means of levers by the action of a governor mounted on the spindle of the basket.
—W. H. C.

Separating liquid from solid matter ; Apparatus for ——. H. C. Colburn, Victor, Colo. U.S. Pat. 1,112,119, Sept. 29, 1914 ; date of appl., July 23, 1913.

A horizontal screw conveyor working in the trough-shaped bottom of a containing vessel forces the material against an abutment or projection and thence into an outlet pipe placed in line with the axis of the screw.—W. H. C.

Dehydrating apparatus. I. S. Joseph, Rahway, N.J. U.S. Pat. 1,112,454, Oct. 6, 1914 ; date of appl., Jan. 14, 1914.

The materials to be dehydrated are carried by flat trucks, running on rails, through a shallow dehydrating chamber constructed parallel with and above the longitudinal combustion chamber of a glass furnace, and heated by radiation from the roof thereof.—W. H. C.

Gas-desiccation. J. F. M. Patitz, Milwaukee, Wis., Assignor to Allis-Chalmers Manufacturing Co. U.S. Pat. 1,113,682, Oct. 13, 1914 ; date of appl., Dec. 21, 1908.

The gas is successively compressed, cooled and expanded, and the condensed moisture removed. The dried gas is then again compressed.—W. H. C.

Dust from exhaust gases ; Apparatus for removing ——. F. Valeur, Gmunden, Austria-Hungary. U.S. Pat. 1,113,848, Oct. 13, 1914 ; date of appl., April 10, 1914.

The gases are passed through a flue which enters tangentially into the base of the chimney. Screens are fixed across the flue at intervals and the cross-section of the flue is contracted at these points to cause a momentary compression and reduction of velocity to allow the dust particles to deposit.—W. H. C.

Filter-press. A. Burger, New Brighton, N.Y. U.S. Pat. 1,112,674, Oct. 6, 1914 ; date of appl., April 8, 1911.

The outlet cocks of the chambers of the filter-press are provided with pneumatic opening and closing devices and are connected by flexible pipes with an apparatus for producing suction or pressure. The pressure or suction causes a piston in the pneumatic device to move in one direction or the other and in doing so to open or close the cock. All the cocks are connected together so that they can be opened or closed simultaneously.—W. H. C.

Distribution of liquids ; Apparatus for the even ——. A. Jonas, Leverkusen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,113,643, Oct. 13, 1914. Date of appl., Dec. 28, 1910.

See Fr. Pat. 421,952 of 1910 ; this J., 1911, 526.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Carbon monoxide in mine air ; Methods of determination and a suggested method of removing it from air. J. Harger. Trans. Inst. Min. Eng., 1914, 533. J. Chem., Met. and Min. Soc., S. Africa, 1914, 15, 59—60.

The determination is based on the reaction $I_2O_5+5CO=5CO_2+I_2$. The sample is collected and measured in the metal cylinder of an apparatus resembling a garden-syringe, the piston-rod of which is graduated to show

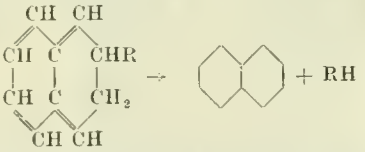
percentages of carbon monoxide. It is passed successively through a solution of bromine, over solid alkali hydroxide, over iodine pentoxide (contained in a coil of glass or silica maintained at about 170° C. in the upper part of a special safety lamp) and (a) through a standard solution of arsenious acid containing sodium bicarbonate and starch, until the latter attains a blue colour, or (b) over metallic copper (to absorb iodine), through a standard solution of alkali hydroxide, and through water containing phenolphthalein tinted by a trace of baryta, until the colour of the last solution is discharged. The volume of the cylinder and the quantity of standard arsenious acid or alkali hydroxide are adjusted so that no indication is obtained unless the air contains more than 0·01% CO; while a dangerous percentage of the latter is indicated within a minute. Carbon monoxide in air is converted into dioxide, at ordinary temperature, by contact with finely divided platinum or palladium; and the use of these or similar catalysts is suggested as the basis for a respirator.
—W. E. F. P.

Firedamp; Electrical detection of ——. G. J. Ralph. Times Eng. Suppl., Oct. 30, 1914, 137.

A PORTABLE apparatus is described for detecting firedamp, and comprises a Wheatstone bridge, of which two of the arms are heated platinum wires, one being in a closed space and the other exposed to the atmosphere. In the presence of firedamp, the resistance of the exposed arm varies. The apparatus can be used with a separate battery or in conjunction with a miner's electric lamp.
—A. T. L.

Coal; The composition of ——. Part II. D. T. Jones and R. V. Wheeler. Chem. Soc. Trans., 1914, **105**, 2562—2565. (See also this J., 1914, 192.)

THE products obtained in the destructive distillation of bituminous coal in a vacuum at not above 350° C. were examined. The occurrence of aromatic hydrocarbons in the oils which were obtained cannot be reconciled with the theory which assumes a breaking off of hydrogen from hydrogenated aromatic nuclei, since this reaction does not take place much below 400° C. An alternative theory according to which complex hydrogenated groups are broken down into a paraffin and naphthalene derivatives, as shown in the equation:—



was supported by the results of the experiments. The neutral oils which were obtained in the distillate were found to consist of mixtures of naphthenes, olefines, and liquid paraffins, such as are obtained by distillation at higher temperatures.—J. N. P.

Briquettes; Rhenish lignite —— in domestic and industrial use. W. Oellerich. Braunkohle, 1913, **11**, 649—655, 665—671, 733—740, 750—755. Chem.-Techn. Rep., 1914, **38**, 193.

LIGNITE in briquettes is found to be as effective as an equal weight of coal, in spite of its lower calorific value, and gives a producer gas better than that from coal, since it contains more carbon monoxide and hydrocarbons, and less nitrogen.—O. E. M.

Bituminous rocks of Estland; Composition of the —— and their decomposition products. Fokin. Gorny Journ. (Russ. Mining J.), 1913, 117. Chem. Techn. Rep., 1914, **38**, 391.

THE bright yellow organic matter of the bituminous rocks of Estland cannot be extracted by organic solvents. It is obtained by leaching out the mineral constituents with different reagents, and contained: H 8·31—9·02, C 72·37—72·82, N 0·56—0·68, O 14·1—16·24, and S 1·6—1·92%; sp. gr. 1·14. The material is slightly hygroscopic, and on dry distillation, yields up to 80% of gas and oil and 20% carbon. Th oil distillate, amounting to about 60%, is readily solubl sp. gr. 0·920—0·945, coefficient of expansion 0·00057 in benzene, but only slightly in petroleum spirit (benzin) It has the viscosity 7·15; and contains: C 80·1—81·85 H 8·71—10·50, O 7·25—8·71, S 0·29—0·40%. Repeate distillation up to 150° C. gives 7·6% petroleum spirit The residues are only suitable for fuel.—J. N. P.

Vaseline oil for internal use. A. Vicario. J. Pharm Chim., 1914, **9**, 149—154.

VASELINE oil or liquid paraffin is obtained from petroleun oils poor in vaseline, and is expressed in the process o preparing solid paraffin. As required by the Frencl Codex it should be of Caucasian origin and consist o hydrocarbons of the series C_nH_{2n}. By comparison of th rate of flow through a fine tube at the ordinary temperatur it should have a viscosity 8—19 times greater than tha of water. The sp. gr. varies between 0·840 and 0·890 Acids and fatty bodies should be absent. American oil which are less pure and limpid than the Russian oils hav a sp. gr. of 0·870—0·945, and give a yellow to a blacl coloration when shaken with concentrated sulphuric acid although they may be satisfactory when tested with 60° acid. The oil can be purified by shaking a litre repeatedl with 50 grms. of concentrated sulphuric acid till the latte ceases to be coloured, then washing with sodium carbonat solution, dehydrating with anhydrous sodium carbonatc and filtering. When subjected to artificial digestio experiments under varying conditions, the oil was un attacked.—F. SHDN.

Lubrication with oils and with colloidal graphite. Maber *See* I.

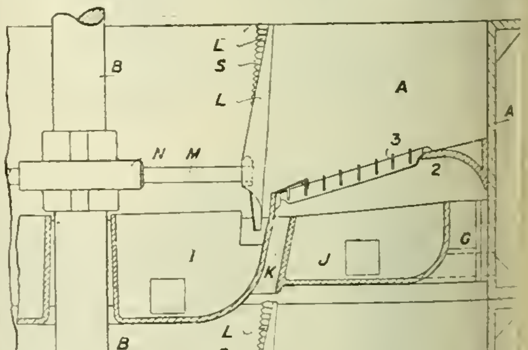
Antiseptic properties of petroleum and its derivative Charitschkow. *See* XIXB.

PATENTS.

Washing gases; Apparatus for —— and for analogo purposes. W. B. Davidson, Birmingham and A. Liversedge, Croydon. Eng. Pat. 9302, April 15, 191

THE gas passes up the passages, *G*, *H*, and is deflecte towards the centre of the vessel, *A*, by the curved baffle. It then passes upwards through the spaces between tl



annular plates, 3, and through the spray to the passage, *G*, next above. The washing liquid in the annular trough, *I*, is lifted by the lower ends of the curved spraying devices, *L*, which are attached by the arms, *M*, and the blocks, *N*, to the central rotating shaft, *B*, and is thrown off as spray from the serrations, *S*. The spray is prevented from passing into the gas passage, *G*, by the annular plates, 3, and collects in the outer annular trough, *J*, from which the liquid overflows through passages, *K*, to the inner trough next below.—W. H. C.

Fuel block or briquet. A. F. van Hall, F. Basenau, and R. C. J. van Haagen, Assignors to Naamlooze Vennootschap Briquet Co. (Briket Maatsch.), Amsterdam. U.S. Pat. 1,114,715, Oct. 20, 1914. Date of appl., Aug. 5, 1910.

See Fr. Pat. 428,900 of 1911; this J., 1911, 1243.—T. F. B.

Coking process. L. L. Summers, Chicago. U.S. Pat. 1,114,065, Oct. 20, 1914. Date of appl., May 13, 1913.

See Eng. Pat. 2069 of 1914; this J., 1914, 1001.—T. F. B.

Gas; Apparatus for generating or producing ——. W. R. Degenhardt, Kalgoorlie, Western Australia. Eng. Pat. 22,618, Oct. 7, 1913.

See Fr. Pat. 464,265 of 1913; this J., 1914, 472.—T. F. B.

Gas-producer. A. von Kerpely, Vienna. U.S. Pat. 1,114,072, Oct. 20, 1914. Date of appl., Oct. 11, 1911.

Manufacture of fireclay gas retorts and the like. Eng. Pat. 25,590. *See* VIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood alcohol. C. Baskerville. J. Ind. Eng. Chem., 1913, 5, 768—772.

Purified wood alcohol is sold in America under the names of "Columbian Spirits," "Colonial Spirits" and "Manhattan Spirits"; in Canada as "Green Wood Spirits" and "Standard Wood Spirits"; and in Germany as "Pro Spirit." Crude commercial methyl alcohol ("wood spirit," "wood naphtha" or "pyroxylic spirit") contains variable proportions of methyl alcohol, acetone, methyl acetate and formate, dimethylacetal, allyl alcohol, aldehyde, methylamine, oil, water, etc. The "tailings" contain furfural, methyl-ethyl ketone, and allyl acetate, with small quantities of paraxanthine. The best commercial wood spirit contains 95% or more methyl alcohol, the common varieties 75 to 95%, and some only 35 to 40%. The crude alcohol as sold usually has a sp. gr. of 0·796 to 0·875 at 15·5° C. In the United States hard woods, especially birch, beech, maple, oak, elm and alder, are preferred for the distillation, though processes for the destructive distillation of sawdust and wood waste have been developed. The wood is seasoned for 1 to 2 years and cut into lengths of 50 in., which are distilled in iron retorts at 400° to 500° F. (200°—260° C.). The volatile products are condensed, the uncondensable portion returned and burned below the retorts. The pyroligneous acid (containing acetic acid, methyl alcohol, acetone, allyl alcohol, phenols, etc.), which separates on the top of the condensed products has a sp. gr. of 1·02 to 1·05. It is used to a small extent in the preparation of an impure iron acetate known as "black iron liquor" or "pyrolignate of iron," but is usually treated to separate the methyl alcohol (about 4%), acetone and acetic acid by neutralisation with lime and fractional distillation. Three stills (2500 galls. each) are commonly used, and the respective distillates contain about 15, 42 and 82% wood alcohol. The residue of gray acetate of lime is exported for the manufacture of acetic acid, whilst the crude wood spirit is sent to a refinery for purification and rectification by distillation from lime or caustic alkalis. Acetone cannot be separated by simple distillation and various methods of separating it have been devised, such as conversion into chloracetones of high b. pt.; conversion into chloroform and distilling the mixture with chloride of lime; crystallisation of the methyl alcohol with calcium chloride; formation of a methyl ester followed by distillation. During 1909—1910 there were in U.S.A. 147 works distilling wood, employing 3039 workmen, and making products (including 8,168,083 galls. of wood alcohol) of the value $9,737,000. In 1913 there were 63 manufacturers of wood alcohol. The exports of wood alcohol (mainly to Germany, Great Britain and Belgium) in 1911 were 2,040,000 galls. valued at $898,000. The crude wood spirit imported into Germany in 1911 amounted to 8,759,300 kilos., of which 4,168,700 kilos. came from Austria, 268,700 kilos. from Sweden, and 4,318,800 kilos. from the United States, whilst in the same year Germany exported 1,739,200 kilos. of purified wood spirit, mainly to France, Italy and Holland. Methyl alcohol is less toxic to lower plants and infusoria but is much more toxic to higher animals and man than ethyl alcohol. Its use should therefore be prohibited in any liquid capable of being taken internally, whilst precautions should be taken to protect workmen from the toxic effects of the vapour.—C. A. M.

Tungsten wire filaments; Preparation of ——. O. Ruff. Z. Ver. deutsch. Ing., 1913, 57, 1615. Chem.-Techn. Rep., 1914, 38, 146.

To prepare a dense, ductile wire suitable for electric lamps, pure tungsten is first obtained by reducing the trioxide in hydrogen, and it is then compressed into rods which are hardened by heating gradually in a current of hydrogen in a tube furnace to 1000° C. for 1 hour. The rods are sintered by heating electrically up to 2850° C., the heating being carried out very carefully and slowly, as the quality of the final product largely depends on this process. The rods are then hammered and rolled at 1200°—1300° C. in a current of hydrogen in a special machine, the operation being repeated until the rods are reduced to the desired diameter. To point the rods before inserting them in the wire-drawing machine the ends of the thicker rods are dipped into molten potassium nitrite, and the thinner ones are made the anode in an electrolytic cell containing potassium cyanide. The finished tungsten wire is silvery white, malleable, tough, ductile and non-magnetic. It is stable in air at ordinary temperatures but oxidises at a red heat so that electric lamps with tungsten filaments have to be exhausted.—T. C.

Coconut and its products, with special reference to Ceylon. Pratt. *See* XII.

Patents.

Coal or other solid material; Apparatus for the distillation of ——. T. Hughes, London. Eng. Pat. 23,418, Oct. 16, 1913.

A vertical metal retort is formed with a central hollow wall containing the heating flues, and intermediate louvred walls arranged so as to support a thin layer of the coal on either side of the central wall, and to provide a collecting chamber for the distillation products adjacent to the outer wall of the retort. The retort may be circular in plan, the walls and chambers being of annular form. The floor of the retort is carried on rails on a base-plate which can be lowered for withdrawing the charge.—A. T. L.

Absorbent or decolorising substance; Manufacture of an ——. Aktiebolaget Kolm. Ger. Pat. 276,343, Oct. 1, 1913.

The bituminous concretions containing uranium, which are found in certain alum shales in Sweden and elsewhere, known as "kolm," are subjected to dry distillation, preceded or followed by extraction with water or acids. The product may be used for decolorising saccharine juices and other liquids.—T. F. B.

Apparatus for the treatment [destructive distillation] of nitrogenous waste, sewage sludge and the like. Eng. Pat. 21,656. *See* XIXb.

Recovery of valuable products [oil and combustible material] from clay and the employment of such products in the manufacture of bricks. Eng. Pat. 28,191. *See* VIII.

III.—TAR AND TAR PRODUCTS.

Benzoic acid ; Quantitative study of the sulphonation of ——. J. Maarse. Rec. Trav. Chim. Pays-Bas. 1914, **33**, 207—238.

Benzoic acid was sulphonated by heating with 4 to 16 times its weight of 93—100% sulphuric acid at from 140° to 209° C. and for from 6 to 91 hours. *o*-Sulphobenzoic acid was not produced under any of the above conditions. The principal product was the *m*-acid together with a small proportion, generally less than 10%, of the *p*-acid. Prolonged heating or high temperatures favoured the formation of the latter. The benzoic acid was incompletely sulphonated when heated to 140° C. with 4 times its weight of 93% acid for not more than 24 hrs. With larger proportions of acid, or more concentrated acid, or at higher temperatures, the whole of the acid was sulphonated.—F. Shdn.

Patent.

Coal-tar or its products ; Treatment of —— *for the removal of the properties therein tending to induce pitch-cancer.* H. W. Robinson, Sedgley. U.S. Pat. 1,114,045, Oct. 20, 1914. Date of appl., Feb. 11, 1914.

See Eng. Pats. 4159 and 10,156 of 1913 ; this J., 1914, 412.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Supply of dyestuffs and colours. Board of Trade Announcement, Nov., 1914.

The Board of Trade has had under consideration the question of the supply of dyestuffs and colours, the deficiency of which at the present time, owing to the cessation of supplies from Germany, is causing great apprehension in the textile trades and in other important British industries. After consultation with the Committee on Chemical Manufactures, appointed in August last under the chairmanship of the Lord Chancellor, it appeared to the Board advisable to take such steps as were possible to develop the immediately available sources of supply, and also to encourage the permanent manufacture of dyestuffs and colours in the United Kingdom on a large scale, so as to guard against any recurrence of the present difficulty. As regards interim steps, arrangements have been made to encourage the immediate expansion of the various existing sources of supply. As regards the permanent supply, after preliminary consultations with representatives of some of the principal bodies of consumers, a meeting was held at the offices of the Board of Trade on Tuesday, November 10, which was attended by representatives of 22 important associations and firms engaged in the colour-using industries. There was laid before the meeting a scheme for the formation of a limited company with a large capital of which the bulk would be subscribed by the consumers of dyestuffs and colours and others interested, the Government indicating their willingness conditionally on this being done to subscribe a certain proportion of the share capital and to guarantee the interest on a large debenture issue for a term of years. Precautions would be taken to preserve the British control of the enterprise and to prevent undue encroachment on other branches of the chemical trades. The meeting was informed that preliminary arrangements had been made enabling the Government to acquire important dye-producing works in this country for the purposes of the new company if established, and that the Government would be prepared to take all necessary steps to secure the acquisition of any other concerns in the United Kingdom whose transfer to the new company might be desirable. The meeting unanimously adopted a resolution approving in principle of a national effort being made by the trade to increase the British supply of synthetic colours and welcoming the assistance of the Government for that purpose. A small committee representing the trades concerned was appointed to confe with the Board of Trade with a view to the elaboration of a scheme on the lines discussed at the meeting.

A further announcement as to the proposed company will be made at an early date.

Phthalein dyestuff of the naphthalene series ; New ——. [*Indicator.*] E. König. Chem.-Zeit., 1914, **38**, 483.

A new dihydroxynaphthophthalein is formed by meltin 2 mols. of 1.6-dihydroxynaphthalene with 1 mol. of phthali anhydride. It forms a scarlet chloride and blue-gree alkali salts. Methylation gives a colourless ether, solubl in sulphuric acid with a scarlet colour and intense fluorescence. It gives dibromo- and di-iodo-compounds and a disulphonic acid, the latter forming a colourless dipotassium salt and a blue-green fluorescent tetra-potassium salt The new phthalein is too sensitive to alkalis to be used in dyeing ; in fact it serves as an indicator and can advantageously replace phenolphthalein in titrating yellow o red solutions.—J. B.

N-Methyl-α-acetylindole. Diels and Dürst. *See* XX

Patents.

Vat dyestuffs of the naphthalene series ; Process for preparin ——. M. Kardos. Ger. Pat. 276,956, Oct. 10, 1913 Addition to Ger. Pat. 276,357 (see this J., 1914, 1045).

Naphthalenedicarboxylic acid imine or acenaphthene quinone oxime, in either of which the NH-group contain an alkyl, aryl, or similar substituent, is fused with a alkali hydroxide, or the dyestuffs obtained according t the principal patent are treated with alkylating or arylatin agents. The dyestuff from N-methylnaphthalenedicar boxylic acid imine dyes cotton pure red shades fast t chlorine and light.—T. F. B.

Azo dyestuff which may be developed on the fibre ; Manufac ture of an ——. C. Müller, Assignor to Kalle und C A.-G., Biebrich on Rhine, Germany. U.S. Pat. 1,113,46 Oct. 13, 1914. Date of appl., Nov. 13, 1913.

See Ger. Pat. 275,660 of 1912 ; this J., 1914, 828.—T. F. B

Azo dyes for wool. P. Hauptmann and A. Rehde, Lever kusen, Germany, Assignors to Synthetic Patents Co. New York. U.S. Pat. 1,113,622, Oct. 13, 1914. Dat of appl., Sept. 4, 1913.

Sulphur [sulphide] dye ; Green ——. J. Flachsländ Assignor to Farbenfabr. vorm. F. Bayer und C Elberfeld, Germany. U.S. Pat. 1,113,766, Oct. 13, 191 Date of appl., Aug. 9, 1911.

See Eng. Pat. 30,104 of 1910 ; this J., 1912, 66.—T. F.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Cellulose ; The methylation of ——. *Part II. Hydroly of methylated cellulose.* W. S. Denham and H. Woo house. Chem. Soc. Trans., 1914, **105**, 2357—2368.

The formulæ given in the previous paper (this J., 191 974) are not to be taken as representing the compositio of definite homogeneous methylcelluloses. Methylation progressive without definite stages ; the percentage combined methoxyl increases with the number of successi treatments ; after six methylations products containi

23·89 and 25·97% OCH_3 were obtained. All the operations were attended by loss of weight, particularly the sixth methylation which was carried out with more concentrated sodium hydroxide (38·3 grms. per 100 c.c.). The highly methylated preparations were hydrolysed at 0° C. by means of hydrochloric acid saturated with the gas at that temperature (cf. Willstätter and Zechmeister, this J., 1913, 822); solution and hydrolysis took place without evidence of profound decomposition. The products of hydrolysis were resolved by a complex series of fractionations with solvents (ether and acetone) and by distillation of methylglucosides prepared from them, into a mixture of methylhexoses; no disaccharide was detected. The substances actually isolated may be classified as follows:—an amorphous monomethylglucose or mixture of several; an amorphous dimethylglucose or mixture of several; a crystalline trimethylglucose; a trace of a crystalline compound, possibly tetramethylglucose. No dextrose was isolated but strong presumption of the presence of unmethylated hexose was obtained. The presence of small traces of tetramethylglucose may be due to the depolymerisation of the cellulose during the methylation treatments or else to the existence of terminal dextrose residues in the cellulose molecule. Substantially the highest product of the methylation of cellulose is represented by trimethylglucose after hydrolysis, which confirms the existence of three free OH groups in the C_6 unit. As the trimethylglucose crystallised readily and was apparently a homogeneous substance, occurring in the a form, there is a presumption in favour of the symmetrical linkage of the dextrose residues in the cellulose molecule. The trimethylglucose isolated in the crystalline form amounted to 10% of the crude product and a further quantity remained in the mother liquors; it did not yield an osazone, and its constitution has not been definitely determined.—J. F. B.

Coconut and its products, with special reference to Ceylon. Pratt. *See* XII.

Paper, pasteboard, and cardboard. Board of Trade Bulletin No. 90.

May be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Patents.

Paper pulp; Apparatus for straining ——. W. W. Beaumont, London. Eng. Pat. 22,094, Oct. 1, 1913. Addition to Eng. Pat. 23,191, Oct. 10, 1912.

The gradual rotation of the straining drum is produced by the action of vibro-motors applied to the cradle arms in which it is mounted, the vertical and horizontal movements of the vibro-motors being compounded to produce a circular or elliptical motion of the drum.—J. F. B.

Pulp-mixing chests and the like. S. Milne, Edinburgh. Eng. Pat. 10,154, Apr. 24, 1914.

The floor of the chest slopes towards the centre and the corners between floor and side are rounded. At the bottom of the central vertical shaft is fixed an agitator with flat vertical blades arranged to force the pulp outwards only. Higher up on the shaft a propeller is fitted with helical blades arranged to force the pulp downwards into the sphere of action of the agitator.—J. F. B.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Adsorption and stabilisation. [*Theory of dyeing.*] J. C. Blucher and E. F. Farnau. J. Phys. Chem., 1914, **18**, 629—640.

To account for certain apparent anomalies in the dyeing of silk, as viewed from the standpoint of the adsorption theory, Bancroft (see this J., 1914, 197, 349, 589) advanced the view that substances when adsorbed may be rendered more stable. Blue hydrous copper oxide, for example, is readily transformed into the black oxide at 100° C., but is stable when adsorbed on wool and also in presence of small quantities of manganous sulphate, and, according to the present investigation, many other salts ($ZnSO_4$, $NiSO_4$, $CoCl_2$, $Al_2(SO_4)_3$, $Cr_2(SO_4)_3$, $MgCl_2$) behave similarly. The stability of blue hydrous cobalt oxide is increased by hydrous nickel oxide (Benedict, J. Amer. Chem. Soc., 1904, **26**, 695) and by adsorbed cobalt sulphate (Hantzsch, Z. anorg. Chem., 1912, **73**, 304); and the effect of the former has been made to serve as a very delicate test for nickel, the rapid change of freshly precipitated blue hydrous cobalt oxide into the normal pink hydroxide being retarded in presence of nickel. The red dyeing of hydrous aluminium oxide from a blue colloidal solution of Congo acid, regarded by Bayliss (this J., 1911, 1093) as evidence of the formation of a red aluminium salt, is considered to be due to the stabilisation by the hydrous aluminium oxide of a red Congo acid unstable in aqueous suspension. Certain anomalies in the dyeing of silk with picric acid dissolved in organic solvents are probably to be accounted for by tautomerism and the slowness with which equilibrium is attained.—A. S.

Patents.

[*Washing*] *Treating textiles, pieces, warps, etc., with liquids; Machine for* ——. J. S. Ainley, Huddersfield. Eng. Pat. 29,928, Dec. 30, 1913. Addition to Eng. Pat. 6970, March 22, 1913 (this J., 1914, 251).

The fabric is cuttled on to an endless apron which travels intermittently over a solid supporting table whereon it is pressed or "possed" by the action of rollers moved intermittently towards and away from the portion of fabric lying on the apron.—J. B.

Cop-dyeing and like machinery. F. Riley and J. H. Riley and Co., Ltd., Bury, Lancs. Eng. Pat. 30,025, Dec. 31, 1913.

The gauze envelope which encloses the cops disposed radially on the outside of a vertical cylinder with deep projecting flanges, top and bottom, and which beds against low projections on the inner faces of the periphery of these flanges, is held in position by rods having reduced shouldered ends passing through holes in the flanges. One of the reduced ends of the rod, considerably longer than the other, is surrounded by a helical spring and the rod may be removed by lifting it against the pressure of the spring.—J. F. B.

Dyeing process. J. J. Fearon, Assignor to C. J. Fox, Philadelphia, Pa. U.S. Pat. 1,113,765, Oct. 13, 1914; date of appl., May 2, 1913.

In dyeing sulphur colours on skein yarn the hanks are first dyed in the usual way and then washed in the same vessel, air being circulated through the mass of yarn during washing, or air may be forced directly into the dye-bath after the dyestuff has been exhausted.—J. B.

Dyeing apparatus and process. A. J. and J. A. Rau, Clifton, N.J., U.S.A. Eng. Pat. 22,595, Oct. 7, 1913. Under Int. Conv., Oct. 17, 1912.

Dyeing machine. R. D. Booth, Philadelphia, Assignor to The Psarksi Dyeing Machine Co., Cleveland, Ohio. U.S. Pat. 1,113,405, Oct. 13, 1914. Date of appl., Oct. 16, 1911.

See Fr. Pat. 436,936 of 1911; this J., 1912, 430.—T. F. B.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Iron, mercury and arsenic ; Determination of —— in sulphuric acid. H. Nisjenson. Chem.-Zeit., Sept. 29, 1914. Pharm. J., Nov. 14, 1914.

In an Erlenmeyer flask 60 grms. of pure zinc are placed, and 100 c.c. of sulphuric acid, freed from HNO_2 by heating, are added by means of a burette. The hydrogen is passed into a small Erlenmeyer flask, containing 1 c.c. of bromine, 100 c.c. of water, and a few drops of sulphuric acid. After about an hour and a half nearly all the zinc will be in solution. The rest of the zinc, which contains mercury, as an amalgam, is filtered, washed and dried. After being mixed with freshly burnt calcium oxide, it is placed in a porcelain crucible, covered with a weighed cover. The upper hollow of the cover is filled with cold water and the crucible is cautiously heated for ten minutes ; the cover is washed with alcohol, dried in a stove, and weighed. The iron will be in the filtrate and is titrated with $N/100$ permanganate. The arsenic is absorbed as AsH_3 by the solution of bromine. The bromine is evaporated by heating the solution. The colourless liquid is reduced by boiling with Na_2SO_3 after which hydrochloric acid is added. The arsenic is titrated with a $N/10$ $KBrO_3$ solution, using indigo as an indicator. One c.c. of $KBrO_3$ solution corresponds with 0·00375 grm. As. This analysis of technical sulphuric acid can be done in about five hours.

Potassium-phosphoric acid-water and ammonia-phosphoric acid-water ; The ternary systems ——. E. G. Parker. J. Phys. Chem., 1914, **18**, 653—661.

Study of the systems mentioned in the title showed that at 25° C. the stable solid phases in contact with solutions containing ortho-phosphoric acid and potassium or ammonium are KH_2PO_4,H_3PO_4 ; KH_2PO_4 ; K_3PO_4 ; $K_3PO_4,3H_2O$; $KOH,2H_2O$; $(NH_4)H_2PO_4$; $(NH_4)_2HPO_4$, and $(NH_4)_3PO_4,3H_2O$. Some experiments were also made with solutions containing both potassium hydroxide and ammonia in addition to phosphoric acid, and the results are tabulated. One of the solutions was allowed to stand over sulphuric acid at 25° C., until both the sulphuric acid and the solution were constant in weight and a solid had separated from the solution. The solution then contained NH_4 1·81, K 4·95 and PO_4 3·96 mols. per 1000 grms., and in the solid which separated, substances having similar optical properties to KH_2PO_4 and K_3PO_4 were recognised ; two double salts, one or both of which was unstable in the air (with liberation of ammonia), or an unstable double salt and a solid solution were also probably present. To obtain a compound containing potassium, ammonia, and phosphoric acid, stable at the ordinary temperature—the chief object of the investigation—it will be necessary to use more acid solutions.—A. S.

Ammonium phosphomolybdate ; Behaviour of —— with ammonium hydroxide. P. B. Sircar. J. Amer. Chem. Soc., 1914, **36**, 2372—2374.

In Woy's method of determining phosphates (Chem.-Zeit., **21**, 442) the phosphoric acid is precipitated as ammonium phosphomolybdate and this is dissolved in ammonia, and the phosphoric acid re-precipitated with magnesia mixture. According to Gibbs (Amer. Chem. J., 1891, **5**, 361, 391) crystals of $2(NH_4)_3PO_4,5MoO_3,7H_2O$, separate when the ammoniacal solution of the phosphomolybdate is allowed to stand. The author finds that when ammonium phosphomolybdate is treated with a moderate quantity of strong ammonia solution, white crystals of $(NH_4)_2Mo_2O_7.3NH_3$, are formed, whilst with a large excess of ammonia the crystals which separate at first, re-dissolve, and subsequently a flocculent precipitate of $(NH_4)_2HPO_4$, is produced, which is very hygroscopic. The compound, $(NH_4)_2Mo_2O_7.3NH_3$, loses ammonia on standing and yields $(NH_4)_2Mo_2O_7$. It sometimes contains 0·1—0·2% of phosphoric acid, probably adsorbed. In a very few cases the salt described by Gibbs (*loc. cit.*) was obtained.—A. S.

Ammonium chloride ; Crystallisation of —— in cubes. A. Dubosc. Bull. Soc. Ind. Rouen, 41, 335. Pharm. J., Nov. 14, 1914.

Cubical crystals of ammonium chloride may be obtained by adding small amounts of copper or iron salts to the crystallising solution. The best results, however, are got by using 1 of ammonium acetate per 1000, added to the solution in the concentration bath at 100° C. The ammonium acetate is probably decomposed to acetamide, and it is to the latter compound that the modification of the crystalline form is due.

Potassium chloride from freshly-cut kelp ; Leaching of ——. A. R. Merz and J. R. Lindemuth. J. Ind. Eng. Chem., 1913, **5**, 729—730.

Large samples of the alga *Macrocystis* were towed through sea-water, and portions subsequently analysed in the wet condition and after drying before and after this treatment. The ash ranged from 2·76 to 3·40 ; KCl 16·97 to 27·87, N 0·79 to 1·07, and I 0·06 to 0·16%. Another sample contained from 16·29 to 32·05% KCl. The stems contained more potassium than the leaves, and the variations were due solely to the difficulty of obtaining an average sample. These results show that freshly-cut kelp does not lose its potassium chloride when immersed in sea-water, at all events for periods up to 135 hours A sample of the rock weed "sea-lettuce" contained 47·41% KCl. Hence its presence in kelp is not detrimental ; but its collection would prove too expensive for it to be an economic source of potash.—C. A. M.

Potassium iodate ; Photolysis of ——. J. H. Mathews and H. A. Curtis. J. Phys. Chem., 1914, **18**, 641—652

A mixture of potassium iodate and iodide in solution is decomposed much more rapidly under the influence of ultra-violet light than is a solution of either salt alone The rate of decomposition of potassium iodate by light decreases slowly when the solution is exposed to the air The decomposition is inhibited when the solution is kept saturated with oxygen, but is greatly accelerated by carbon dioxide. In the photolysis of potassium iodate the two reactions :

$KIO_3=KI+3O$;

$5KI+KIO_3+6CO_2+3H_2O=6KHCO_3+6I$. probably occur, the second with a much higher velocity than the first.—A. S.

Silver nitrate solutions ; The solvent properties of ——. The silver voltameter. III. T. M. Lowry. Roy. Soc Proc., 1914, **A91**, 53—71.

Among impurities which may influence the weight of the deposit in the silver voltameter are substances which although almost insoluble in water dissolve in silver nitrate solutions and are thus precipitated when such solutions become impoverished during electrolysis. The influence of dilution and of temperature upon the solubility of silver chloride, silver bromide and silver sulphide in silver nitrate solutions is indicated in a series of solubility curves.. The solubility of silver chloride in solutions of hydrochloric acid and of sodium chloride is also similarly recorded. Black silver sulphide was permanent in contact with silver nitrate solutions up to 10% strength but with increasing concentration the change to the yellow variety was more and more rapid.—J. R.

Hydrogen peroxide ; Preservation of ——. J. H. Walton jun., and R. C. Judd. Z. physik. Chem., 1913, **83**, 315. Chem.-Techn. Rep., 1914, **38**, 85.

Concentrated solutions of sodium chloride will preserve hydrogen peroxide ; the time required for the decomposition of half the peroxide in a solution is approximately doubled by the addition of 1 mol. NaCl per litre. Sulphuric acid even in a concentration of 0·00066 grm. per litre has a pronounced retarding influence on the decomposition. A still better preservative is acetanilide, which is effective even in solutions containing positive catalytic agents, such as sodium hydroxide, and also soluble matter from glass.—C. A. M.

Sulphur; A new modification of ——. A. H. W. Aten. Z. physik. Chem., 1913, **83**, 442. Chem.-Techn. Rep., 1914, **38**, 247.

The enhanced solubility in sulphur monochloride of sulphur previously heated to 170° C. points to the presence of a maximum of 5% of the new allotrope ($S\pi$), which, however, has not been isolated. Similar solubility relationships hold for carbon bisulphide and toluene; and all the solutions are yellow.—J. R.

Glucinum (beryllium) sulphate and its hydrates. F. Taboury. Compt. rend, 1914, **159**, 180—182. J. Chem. Soc., 1914, **106**, ii., 728.

The progressive dehydration, by heating, of the tetrahydrate of glucinum sulphate confirms the existence of the di- and mono-hydrates, the former being obtained at 55°—60° C. and the latter at 100° C., and indicates the existence of a hemihydrate obtainable at 150°—160° C. The anhydrous salt obtained at 250° is stable up to 530°—540° C., and thus allows of the estimation of glucinum in the form of its sulphate. Glucinum sulphate does not form acid salts even when dissolved in sulphuric acid.

Terbium. C. James and D. W. Bissel. J. Amer. Chem. Soc., 1914, **36**, 2060—2066.

Terbium was rapidly separated from gadolinium by fractional crystallisation of the bromates, about 30 grms. of very pure terbium oxalate, giving a black oxide, being obtained from some kilos. of mixed bromates of gadolinium, terbium, dysprosium, holmium, and, in traces, yttrium and erbium. The absorption spectrum given by a strong solution of terbium nitrate consisted of a single band in the blue, and the authors conclude from their investigation that there is only one terbium. A mixture of air and gas directed upon terbium peroxide or upon gadolinium oxide containing terbium peroxide, heated almost to redness, caused incandescence, the gas usually taking fire.—F. Sodn.

Neoytterbium; Isolation of ——. J. Blumenfeld and G. Urbain. Compt. rend., 1914, **159**, 323—326. J. Chem. Soc., 1914, **106**, ii, 731.

The authors have submitted the earths of the ytterbium group, in the form of their nitrates, to a process of fractional crystallisation (compare Urbain, J. Chem. Soc. (Abs.), 1907, ii, 956; 1908, ii, 108), following the stages in the purification by measuring the coefficients of magnetisation of each fraction. After four thousand crystallisations they have obtained eight successive fractions having the same coefficient, indicating the isolation of a definite compound. The metal of the nitrate corresponding with these fractions they call "neoytterbium." The paramagnetism of its oxide is 33·6, and the atomic weight of the metal is 173·54. The spectra of these fractions show but very feebly the strongest rays of luteeium (compare Urbain, *loc. cit.*), or of thulium (compare Soret, J. Chem. Soc. (Abs.), 1880, 7, and Cleve, *ibid.*). The spectra do not contain the rays of aldebaranium, as indicated by Auer von Welsbach (compare this J., 1914, 21).

Radium: uranium ratio in carnotites. S. C. Lind and C. F. Whittemore. J. Amer. Chem. Soc., 1914, **36**, 2066—2082.

Samples of carnotite representing large quantities (a few hundred pounds to several tons) of ore showed a Ra : U ratio identical with that of pitchblende, $3{\cdot}33 \times 10.^{-7}$ whereas those from a few pounds of ore tended to exhibit abnormal (high or low) ratios. This is explained by supposing that "transposition" of radium has occurred within the ore bed, producing local differences which are equalised in mixing large quantities of ore. Radium was determined by the emanation method in one operation, either by solution or by ignition, and always after attainment of equilibrium in sealed glass tubes, for a month or more; fusion with carbonate or fusion followed by solution gave low results. The "emanating power" of carnotite was found to be 16–50%.—F. Sodn.

Neon and helium; Production of ——, *by the electrical discharge.* J. N. Collie, H. S. Patterson, and I. Masson. Roy. Soc. Proc., 1914, A **91**, 30—45. (See also this J., 1913, 231.)

Various forms of apparatus employed for the passage of the electrical discharge through hydrogen at low pressure are described. With every precaution against atmospheric contamination by leakage the formation of neon and helium was repeatedly observed, although occasionally negative results were obtained. The absolute and relative amounts of neon and helium varied considerably in the different experiments. The possibilities of leakage, permeation, and occlusion are dismissed in favour of the actual production of the inert gases through the agency of the discharge.—J. R.

Charcoal; Absorption of gases by —— *at low temperatures.* G. Claude. Comptes rend., 1914, **158**, 861—864.

Hydrogen forms an exception to the general rule that the absorption of a gas by charcoal at low temperatures depends upon the ease of liquefaction of the gas. In comparative experiments on the absorption of nitrogen, neon, helium and hydrogen by coco-nut charcoal at —195·5° and —182·5° C., using an arrangement similar to that employed by Dewar (Proc. Roy. Inst., 1907, June 7), at the same pressures the absorption of hydrogen was enormously greater than that of either helium or neon, although, in accord with Dewar's observation, not so great as that of nitrogen.—G. F. M.

Air and ammonia; Explosibility of mixtures of ——. E. Schlumberger and W. Piotrowski. J. Gasbel., 1914, **57**, 941—943. J. Gas Lighting, 1914, **128**, 365.

An explosion at an ice-factory by which damage to the factory and injury to the stoker occurred, was investigated by H. Bunte, who found that the explosion must have been one of a mixture of air with ammonia that had escaped from the refrigerator. The authors have further investigated the subject. They find that the chief reason why mixtures of air and ammonia in experimental trials have not exploded hitherto, is that narrow tubes like burettes, etc., have been used, and the cooling effect of their walls is proportionately great in the case of such explosive mixtures. The mode of ignition, too, is known to have an effect in such cases. A spherical vessel is most favourable to complete combustion, and ignition should take place at the centre of the vessel. In the present research, the authors produced a spark of the same strength for all the ignitions by employing a ten-volt accumulator with induction-coil of special construction and a long pendulum contact-breaker. This pendulum, liberated each time from the same position, made contact for precisely the same period through a platinum point attached to its bob, passing over the surface of mercury which was forced from a levelling vessel to the top of a tube slightly over an inch in diameter. The pendulum was connected with one pole and the mercury with the other pole of the coil. The electrodes in the explosion vessel were of 0·3 mm. platinum wire, the ends being 6 mm. apart. It was found that explosion occurred with perfectly dry ammonia, and air dried only by passing it over concentrated sulphuric acid, whereas if the air were further dried by passage over phosphorus pentoxide, no explosion occurred. A state of constant humidity was then secured for the further experiments by passing the air through dilute sulphuric acid of sp. gr. 1·340, having an aqueous vapour tension at 20° C. of 8·494 mm. Using as explosion-vessel a spherical bulb of 110 mm. diam. and with a capacity of about half a litre, it was found that under these conditions the explosive mixtures of air and ammonia ranged from 16·5 to 26·8% by vol. of ammonia in the mixture. In a Bunte burette (19 mm. diam.), with a spark-gap of 2 mm., no explosion could be obtained, but continuous combustion was observed between the limits of about 19 and

25% NH_3. The mixture corresponding with the combining proportions of ammonia and oxygen is 21·9% by vol. of NH_3 with air.

Patents.

Phosphoric acid; Method of manufacturing ——. I. Hechenbleikner, Charlotte, N.C., Assignor to Southern Electro-Chemical Co., New York. U.S. Pat. 1,112,211, Sept. 29, 1914; date of appl., Feb. 7, 1914.

Natural phosphate rock, silicious material, and carbon are heated so as to produce vapours of phosphorus which are withdrawn with the furnace gases, the current of gases being broken up and mixed with oxygen (*e.g.*, by admitting this gas as a counter-current), and the phosphoric acid absorbed by an aqueous liquid in towers operated on the counter-current system. The spent gases may be passed through a scrubber.—F. Sodn.

Barium oxide; Method of preparing ——. L. E. Saunders, Niagara Falls, N.Y. U.S. Pat. 1,112,721, Oct. 6, 1914; date of appl., Feb. 5, 1912.

Barium sulphate is decomposed by the heat of an electric arc under non-reducing conditions, obtained by maintaining the material out of contact with the arc.—O. R.

Epsom salts; Process of making ——. G. Clarke, Assignor to The Ohio Chemical and Manufacturing Co., Cleveland, Ohio. U.S. Pat. 1,112,770, Oct. 6, 1914; date of appl., Aug. 2, 1913.

A hot solution of ferrous sulphate is partially neutralised with a double oxide of calcium and magnesium, and the neutralisation completed with magnesium oxide. The precipitated ferrous hydroxide is removed, and magnesium and calcium sulphates are recovered from the solution by fractional crystallisation.—F. Sodn.

Zinc oxide; Manufacture of ——, *and apparatus therefor.* J. A. Singmaster, Palmerton, Pa., Assignor to New Jersey Zinc Co., New York. U.S. Pats. 1,112,853 and 1,112,854, Oct. 6, 1914; dates of appl., Jan. 9 and 18, 1912.

A charge of zinc ore and combustible material is carried through a tunnel furnace on a number of perforated grates, each mounted on a truck and provided with its own air supply. Air is forced through the bed, the current being increased as the material passes forward, and the zinc oxide fumes are discharged at successive points through a number of off-takes in the roof of the furnace. —O. R.

Alkali silico-aluminate richer in alkali than felspar [*, and hydrochloric acid*]*; Method for making* ——. A. H. Cowles, Assignor to The Electric Smelting and Aluminium Co., Sewaren, N.J. U.S. Pat. 1,111,881, Sept. 29, 1914; date of appl., Sept. 11, 1913.

Material containing silica, alumina, and carbon, disposed to present a relatively extended surface, is subjected to the action of water vapour and salt vapour in a rotary furnace. For example, a mixture of clay, salt, and finely-divided carbon, agglomerated into small masses, is fed into the converting zone of the furnace, whilst steam, air, and water are blown in at the lower end, the excess of water vapour being sufficient to aid in condensing the hydrogen chloride produced. Portions of the furnace susceptible to attack by the acid are kept at a temperature above the b.pt. of strong hydrochloric acid.—F. Sodn.

Alkali cyanogen compounds; Making of ——. J. C. Clancy, Assignor to Portland Gold Mining Co., Colorado Springs, Colo. U.S. Pat. 1,112,893, Oct. 6, 1914; date of appl., June 22, 1912.

Calcium cyanamide is heated with alkali sulphide or a mixture of this and another alkali salt, *e.g.*, with its own weight of a mixture of equal weights of sodium sulphide and chloride, in presence of carbonaceous material. —F. Sodn.

Sulphuric acid; Apparatus for producing ——. E. H. McFarland, Cincinnati, Ohio, Assignor to General Electric Co., New York. U.S. Pat. 1,112,424, Sept. 29, 1914. Date of appl., May 10, 1913.

See Eng. Pat. 15,293 of 1913; this J., 1914, 482.—T. F. B.

Continuous stills for the dissociation of chemical solutions by heat. Eng. Pat. 337. *See* I.

VIII.—GLASS; CERAMICS.

Ceramic industry; Sanitary conditions in the ——. Leymann. Zentralbl. Gew.-Hyg., 1913, **1**, 94. Chem.-Techn. Rep., 1914, **38**, 190—191.

In 1903, 1672 factories out of 14,000, employing 10,360 workers out of 140,000 used lead compounds. Diseases of the respiratory organs are not more numerous than in other trades. Among 66,000 workers in 429 factories between 1900 and 1903 there were annually 88 cases of lead poisoning (0·13%), on the average. In factories where galena is used no cases were observed.—O. E. M.

Patents.

Tunnel dryers for drying products of clay and the like material. A. R. Stevenson, Glasgow. Eng. Pat. 23,174, Oct. 14, 1913.

Air is heated by passing along pipes arranged in a flue which extends along the base of the tunnel and is heated from any available source. The flue is covered with thin plates, and the heated air is led from the longitudinal heating pipes by means of a number of vertical pipes to the top of the drying chamber. Air and moisture are withdrawn from near the bottom of the drying chamber by vertical downward pipes, arranged in the wall of the tunnel dryer, and pass into a longitudinal flue, below the heating flue, which communicates with the chimney stack.—W. C. H.

Clay or the like; Apparatus for drying products of ——. L. E. Rodgers, Chicago, Ill. U.S. Pat. 1,103,435, July 14, 1914; date of appl., Nov. 18, 1913.

The articles to be dried are run on trucks through a number of non-communicating chambers, arranged side by side. Conduits into which hot and cold air can be forced are arranged transversely across the chambers, and communicate with mixing chambers through openings controlled by valves. Air feeder-ducts are arranged longitudinally beneath the drying chambers and communicate with them through openings in the top walls of the ducts which are connected at one end with the air-mixing chambers. The hot and cold air conduits are placed midway between the ends of the drying chambers in order to supply air to the opposite ends of the chambers. —W. C. H.

Gas retorts and the like; Manufacture of fireclay ——. G. V. Evers, Stourbridge, Worcester. Eng. Pat. 25,590, Nov. 8, 1913.

To avoid handling the retorts or other articles between the processes of shaping and firing, they are shaped in the firing kiln, by means of a machine carried on overhead rails.—A. T. L.

Clay; Recovery of valuable products [oil and combustible material] from —— and the employment of such products in the manufacture of bricks and the like. G. P. Crowden, Peterborough. Eng. Pat. 28,191, Dec. 6, 1913.

A retort is fixed in one of the chambers or hot flues of a brick kiln, and is so arranged that material can be charged into it and products of distillation withdrawn and collected in a hydraulic main. Clay or shale, containing bituminous substances, is thus distilled by the heat of the brick kiln, steam, also superheated by the heat of the kiln, being at the same time blown into the retort to assist distillation, and the residual baked clay may be mixed with other clays for brick manufacture. The liquid and gaseous products of distillation are applicable for heating the kiln itself, for illuminating, power generating, or other purposes.—O. R.

Glass; Manufacture of sheet ——. H. K. Hitchcock, Tarentum, Pa., Assignor to Hitchcock Experiment Co. Reissue No. 13,804, Sept. 29, 1914, of U.S. Pat. 805,064, Nov. 21, 1906. Date of appl., June 18, 1906.

See this J., 1905, 1306.—T. F. B.

Dehydrating apparatus. U.S. Pat. 1,112,454. *See* I.

IX.—BUILDING MATERIALS.

Portland cement; Alterations in Austrian standards for ——. Cement 1914, 14—15, 34—35, 65—66. Chem.-Techn. Rep., 1914, **38**, 270.

The cement must not contain more than 2·5% SO_3 or 5% MgO. For determining the setting time, a needle of 1 sq. mm. cross-section, weighted with 300 grms., is prescribed. The briquettes used for testing the strength of the cement are to be kept in air for the first 24 hours, and then some entirely in water at 15°—18° C. until the test, and others for 6 days in water and afterwards in air at 15°—20° C. The briquettes kept in water only, must have after 7 days a tensile strength of 12 kilos. and a crushing strength of 120 kilos. per sq. cm., and after 28 days 20 and 200 kilos. in the respective cases. The briquettes kept in water and afterwards in air, must have after 28 days, a tensile strength of 25 kilos. and a crushing strength of 250 kilos. per sq. cm. The directions for the preparation and treatment of the briquettes before testing are also altered.—J. H. L.

Plaster; Mixing and setting of ——. A. Astruc and A. Juillet. J. Pharm. Chim., 1914, **9**, 5—19.

A consideration of the qualities of plaster for surgeon's work. For mixing, 60 grms. of water per 100 grms. of plaster are recommended: setting is nearly complete after 20 mins. The time of setting of the plaster is retarded by the presence of mucilaginous substances, such as marsh-mallow, gum arabic, linseed, etc.; powdered marsh mallow in particular, even when only 0·5% is present, more than doubles the time required; setting is accelerated by alum and common salt. The rise in temperature on mixing and the duration of the heat reaction vary with the quality of the ingredients used. When marsh-mallow is present, the duration of the reaction is increased, but the rise of temperature is less. Alum and sodium chloride cause a great increase in the rise of temperature and shorten the time. The relations between rise of temperature and time are shown graphically by means of curves.—J. H. J.

Zinc in treated wood; Determination of ——. F. C. Frary and M. G. Mastin. J. Ind. Eng. Chem., 1913, **5**, 738—739.

American railroad companies buy sleepers specified to contain ½ lb. $ZnCl_2$ per cb. ft.(= about 0·5% Zn). The common method of determination is to heat the sample with sulphuric acid, add nitric acid, and heat till all organic matter is destroyed, when the solution is diluted, iron removed, and zinc precipitated as sulphide and weighed as oxide. This gives satisfactory results with woods other than oak (especially red oak), the organic matter of which is not completely destroyed, while only about half of the zinc is subsequently precipitated. To obviate the difficulty 2 grms. of the dried shavings are fused in a nickel basin with a little water and about 30 grms. of pure potassium hydroxide, with frequent stirring, and minute fragments of potassium nitrate (about 0·5 grm. in all) added from time to time until all organic matter has been oxidised. After cooling, the mass is dissolved in water, 15 to 20 c.c. of bromine water added, the liquid boiled, the nickel oxide separated, and the filtrate and washings rendered faintly acid with hydrochloric acid. Sodium sulphite is then added, the amount of free hydrochloric acid brought to 2 to 6% by vol., the liquid diluted to 400 c.c., heated to boiling, and titrated with potassium ferrocyanide, with uranium nitrate as indicator, whilst a blank determination is made simultaneously. The method gives good results with oak impregnated with both creosote and zinc chloride.—C. A. M.

Patents.

Slates or tiles; Manufacture of artificial ——. J. M. Macdonald and J. J. Keswick, London. Eng. Pat. 21,579, Sept. 24, 1913.

Pulverised material, for example refuse slate, with or without the addition of sand, powdered brick or stone and colouring materials, is mixed with approximately 15% of its weight of Portland cement. The mixture is made into a semi-plastic mass by water or a diluted solution of sodium borosilicate, pressed into the desired shapes, allowed to harden and then immersed in a solution of sodium borosilicate of 35° to 55° Tw. (sp. gr. 1·175—1·275) and finally dried.—W. C. H.

Magnesium cement; Process of making ——. W. Siegmann, Assignor to M. V. Gault, Baltimore, Md. U.S. Pat. 1,102,358, July 7, 1914; date of appl., April 7, 1911.

Magnesium oxide, magnesium sulphate, sodium chloride, kieselguhr and if desired asbestos and colophony are mixed with water to produce a plastic mass to which carbon bisulphide is also added "to increase evaporation of moisture and the dissolution of other ingredients."
—W. C. H.

Cement; Process of, and apparatus for making ——. H. L. Duncan, New York. U.S. Pats. (a) 1,113,606 and (b) 1,113,933, Oct. 13, 1914; dates of appl., Nov. 13, 1903 (renewed March 10, 1914) and June 20, 1910.

(a.) Molten furnace slag is congealed into a sheet of plastic material, which is broken up and piled on a conveyor, where it is annealed and then pulverised and cooled. The material thus obtained containing substantial proportions of active cement material, is mixed with inert cement material, produced by treating furnace slag, and also with Portland cement. (b) The apparatus comprises a pair of adjustable congealing rolls, through which cooling fluids can be circulated; portions of the rolls, on which fluid cooling jets can play, are arranged to work within cooling chambers. Substantially molten furnace slag is supplied to the larger congealing roll by a corrugated, cooled feed roll. The stream of plastic slag thus produced is disengaged from the larger congealing roll by a scraper fixed to the feed roll and fed on to a stationary cooled conveyor, with which a rotating breaker co-operates and disintegrates the slag. Gaseous and liquid cooling jets are directed on to the breaker and stream of slag on the conveyor. A moving conveyor, provided with an adjustable speed device and enclosed in an annealing chamber, receives the slag particles, which when discharged from the conveyor, come in contact with fluid cooling jets and pass to a rotating disintegrator; from this the slag material passes by a shoot to a rotating, ribbed cooling cylinder in which the active slag cement material collects.—W.C.H.

Hardening cementitious materials. A. C. Horn, New York. U.S. Pat. 1,114,140, Oct. 20, 1914 ; date of appl., Oct. 9, 1912.

PORTLAND or other hydraulic cement is mixed with finely divided magnetite, ferrous sulphate and manganese dioxide, worked up into a plastic mass with water and formed into any desired shape.—B. N.

Concrete : Aggregate for ——. F. M. Haldeman. Assignor to The Master Builders' Co., Cleveland, Ohio. U.S. Pat. 1,113,555, Oct. 13, 1914 ; date of appl., May 4, 1914.

THE surface portions of a concrete structure are formed of cement and finely disintegrated partices of metallic iron coated with a thin and substantially uniform film of magnetic oxide.—W. C. H.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ; Addition of titanium iron alloys to foundry ——. H. Braune. Jernkontorets Annaler, 1913, **68**, 822. Chem.-Techn. Rep., 1914, **38**, 273. (See also Venator, this J., 1910, 570 ; Slocum, this J., 1911, 899.)

EXPERIMENTS at the *Kgl. Technischen Hochschule* of Stockholm indicate that the addition of titanium to foundry iron removes nitrogen more readily than it deoxidises. 0·25% Ti removes as much nitrogen as larger quantities. The transformation point, texture, specific gravity and mechanical characters of the iron are not altered. Resistance to strain is increased by addition of 0·25% of ferrotitanium. The quality of steel appears to be improved by addition of 0·25% Ti. By embedding the iron in 90% titanium and heating in a cementation furnace for 14 days ; the superficial portions absorbed 0·1% Ti.—J. H. L.

Titanium in iron and steel ; Colorimetric determination of ——. C. R. McCabe. J. Ind. Eng. Chem., 1913, **5**, 735—736.

Amounts above 0·02% : Two grms. each of the sample and of steel free from titanium are dissolved in 80 c.c. of sulphuric acid (1 : 3), 4 c.c. of nitric acid (sp. gr. 1·2) added, and the solutions boiled until free from nitrous fumes, and (in the case of cast iron) filtered from silica. The liquids are diluted so that in equal volumes the colours match, and an addition of 2 c.c. of 3% hydrogen peroxide is made to each. Standard titanium solution is then added to the solution of non-titanium steel to match the colour of the test sample. The standard solution is prepared by heating 100 grms. of ferro-titanium with about 50 c.c. of strong hydrochloric acid and (after some moments) 5 c.c. of nitric acid (sp. gr. 1·12). After evaporation of about half of the acid the liquid is diluted with 15 to 20 c.c. of water and the ferro-titanium treated with more of the mixed acids until sufficient has been dissolved (about 12 times). The filtrates are evaporated until titanic acid separates, and then freed from iron by extraction with ether, united, heated with 150 c.c. of sulphuric acid (1 : 3), and filtered. The filtrate is diluted to about 700 c.c., boiled with excess of ammonia, and the precipitated hydrated titanic acid washed free from chlorides by decantation, dissolved in 50 c.c. of sulphuric acid (1 : 1) and diluted to a litre. The strength is determined by precipitation with ammonia, and the solution diluted so as to contain 0·0002 grm. of titanium per c.c. *Amounts below* 0·02% :—The solutions of the sample and of non-titanium steel are evaporated to 10 c.c., transferred to separating funnels (the dishes being rinsed with about 15 c.c. of dilute hydrochloric acid, 2 : 1), and shaken with 50 c.c. of ether (free from alcohol) to extract the iron. The lower layers are drawn off, each diluted with 225 c.c. of hot water, and boiled with ammonia in slight excess, the precipitates washed with hot water, and dissolved in 10 c.c. of sulphuric acid (1 : 3), and filtered into 30 c.c. colorimetric cylinders. The filtrates and washings which should be equal (15 to 18 c.c.) in both cases, are then treated with 3 c.c. of 3% hydrogen peroxide. In the presence of even 0·001% Ti a yellow tint quite distinct from the green tint of the non-titanium solution will be seen, and its amount may be determined as described above. In the case of cast iron the sample is dissolved in hydrochloric acid, the solution filtered, and the residue ignited (and after volatilisation of silica with hydrofluoric acid and a few drops of sulphuric acid) fused with 1 grm. of sodium carbonate. The mass is dissolved in hydrochloric acid, and added to the main solution, which is then extracted with ether, etc.—C. A. M.

Cementation of iron ; Recent developments and researches on the ——. W. Guertler. Intern. Zeits. Metallog., 1914, **6**, 196—199.

CEMENTITE can only be formed by direct synthesis during cementation if the carburising agent (*e.g.*, acetylene, cyanogen) is less stable than cementite. In cementation, the more or less pure γ crystals become saturated with carbon on their surfaces, and the carbon then diffuses from the surface into the interior and then from crystal to crystal. The diffusion from one crystal to another appears to be independent of the carburising agent but increases with the temperature. Since the carburising agent at the steel surface has to be continuously renewed, fluid agents are the best. Fe_3C separates out of the γ-crystals, on the side remote from the carburising agent, when they are saturated with respect to the agent and supersaturated with respect to Fe_3C. If the carburisation is sufficient, free carbon is obtained either by disintegration of cementite or by separation from the supersaturated γ-crystals.

Some results obtained by Hatfield (see also this J., 1911, 427) are given in the following table :—

Original composition of steel.						Carbon content after 7 days' cementation at 950°—1000 C.		
C.	Mn.	Si.	S	P.	Total C.	Free C.	Combined C.	Added C.
%	%	%	%	%	%	%	%	%
3·30	trace	0·074	0·01	0·01	3·30	3·15	0·15	0
0·85	0·26	0·093	0·01	0·01	1·54	0·10	1·44	0·69
1·05	0·31	0·084	0·01	0·01	1·46	0·26	1·20	0·41

Steel castings ; Micro-structure of ——. W. Tassin. J. Ind. Eng. Chem., 1913, **5**, 713—717.

STEEL castings in the "green" (*i.e.*, from the mould) show a coarsely crystalline regular network the meshes of which usually intersect at some angle of an octahedron. This structure is termed "ingotism." When the steel is annealed at the right temperature for a sufficient time, the structure becomes finely granular and uniformly distributed. With insufficient time at the right temperature traces of the original structure will be seen, whilst with too long a time the new structure will be much coarser and show irregular areas. These become more pronounced when the temperature is too high. When steel which has been correctly annealed is sensitive to shock and to suddenly applied loads, the microstructure will show the presence of slag, sulphides or other impurities, or even minute cracks following the lines of the impurities. When used in conjunction with a set of standards the metallographic method will give information not easily obtainable in any other way.—C. A. M.

Steel; Production of granular pearlite by heating —— in an electric vacuum furnace. W. P. Ishewsky. Intern. Zeits. Metallog., 1914, **6**, 199—200.

STEEL containing: C 0·83, Mn 0·38, and S 0·03%, was heated in an electric vacuum furnace to 800° C. and then cooled to 680° C. This was repeated eleven times at intervals of 20 mins. During cooling the transition temperature, which had a slight tendency to rise, was 701° C. to 712° C. After treatment the structure was coarser, the granular pearlite had increased, the lamellar was less in amount but composed of larger particles, the cementite had increased, and free ferrite was present. It was shown by treating a second sample containing: C 0·37, Si 0·38, Mn 0·98, P 0·05 and S 0·03%, that this result was not due to the original presence of cementite. The mechanical properties were:—

Sample.	Tensile strength.	Elongation.
	tons per sq. in.	%
(1) 0·83% C., before treatment	48·7	11·8
(1) 0·83% C., after ..	34·2	19·75
(2) 0·37% C., after ..	31·2	21·25

—W. F. B.

Steel; Belaiew's studies on the structure of ——. W. Guertler. Int. Zeits. Metallog., 1914, **6**, 72—89.

THE principal photomicrographs and descriptions published by N. T. Belaiew of the structures which may be developed in steels are given and discussed. *Primary crystallisation* from the molten metal gives rise to a dendritic structure (see this J., 1912, 539). *Segregation structures.* As the steel cools, cementite or ferrite separates, and independent grains of γ-solid solution are formed. If the segregations of cementite or ferrite become forced to the boundaries of the individual crystals the "net-structure" results. The size of the meshes is connected directly with the rate of cooling and the temperature of annealing. The segregates may, on the other hand, be confined within the γ-crystals, when their orientation corresponds to the crystal-structure of each grain, and Widmanstetten figures are formed (see this J., 1910, 954). Normal martensite is an arrested and imperfect Widmanstätten structure. The "net" and Widmanstätten structures may occur together. *Pearlite formation.* The γ-crystals on further cooling are resolved into pearlite. Belaiew distinguishes between streaky, wavy, and onyx-like pearlite. The structure may be apparent only under high magnifications and Belaiew does not agree with the view that troostite is an ultramicroscopic structure and that sorbite represents an intermediate stage between troostite and pearlite. Pearlite is structurally unstable, the constituents tending to segregate. This tendency is considerably increased in the presence of excess of either constituent. In this way cementite boundaries of grains may extend into the grains forming pseudo-dendrites. The author questions Belaiew's view that the characteristic of damascene steel is the complete resolution of pearlite into ferrite and cementite.

—T. ST.

Chrome and tungsten steels; Permanent magnetism of certain ——. M. B. Moir. Phil. Mag., 1914, **28**, 738—748. (See also this J., 1914, 552.)

THE residual magnetism of steels is of varying magnitude and is retained with different degrees of firmness according to the composition, the physical condition as determined by previous heat treatment, and the size and shape of the sample of metal. The retentive power was determined by measuring the strength of negative magnetic field necessary to reduce the residual magnetism to zero: this negative field is equal and opposite to the coercive force of the magnet. The amount of residual magnetism in the alloys investigated was not found to bear any relationship to the permanent magnetism or coercive force. Annealed specimens of chrome steels possessed only a negligibly small quantity of permanent magnetism, while quenched specimens retained sufficient to serve as useful magnets. In a number of chrome steels containing Cr from 1 to 20%, but otherwise similar, the total residual magnetism fell in proportion to the Cr content. The permanent magnetism retained after submitting to repeated mechanical shocks and temperature fluctuations was greatest with 8% Cr, while the coercive force was greatest with 16% Cr. The results vary also according to the dimensions of the magnet: as the ratio of length to breadth is increased, the Cr-content must be diminished to give the same magnetic properties. Tungsten-steels gave a much higher magnetic intensity and permanent magnetism than chrome-steels, yet the coercive force and retentivity were in all cases lower than with the steels containing 8% Cr. With steels containing from 2·9 to 11·6% W, quenched from 900° C., a continuous fall in the total residual magnetism occurred with increase of tungsten, while the permanent magnetism remained approximately constant up to 8·7% W.—I. N. P.

Ferro-nickels; Dilatation of —— over a wide temperature interval. P. Chevenard. Comptes rend., 1914, **159**, 175—178. J. Chem. Soc., 1914, **106**, ii., 708—709.

A STUDY of the dilatation and contraction of alloys of iron and nickel, varying from pure iron to pure nickel, over a temperature range from —195° to 750° C. The difference between the linear dimensions of bars of the alloys before and after heating are a measure of the amplitude of the irreversible transformation. These differences gradually tend towards zero on passing from iron to Fe_2Ni, which is apparently the limit of irreversible alloys. The alloys between Fe_2Ni and FeNi, have abnormal, quasi-reversible properties. For $FeNi_2$, the dilatation takes place according to a parabolic law between 0° and 800° C.

Silicol (ferrosilicon); The analysis of —— and other silicon alloys used for the production of hydrogen. G. F. Jaubert. Rev. gén. Chim. pure et appl., 1913, **16**, 341—347. Chem.-Techn. Rep., 1914, **38**, 380.

FIVE portions (10 grms. each) of the ferrosilicon contained in thin paper thimbles are added successively to 50 c.c. of 40% sodium hydroxide solution in a 2-litre flask and kept at 80° C. The evolved gas is led through 3 wash-bottles containing respectively pure water, bromine water (to oxidise hydrogen phosphide), and 10% sodium hydroxide solution (to remove bromine vapour). To the last wash-bottle, in which a thermometer hangs, is connected a gas receiver. The volume of gas obtained is reduced to 0° C. and 760 mm. 50 grms. of silicol yield 70 to 75 litres of hydrogen. The contents of the bromine water wash-bottle may be used for the determination of phosphorus.—T. ST.

Zinc-gold slime; Notes on treatment of ——. H. A. White. J. Chem., Met., and Min. Soc., S. Africa, 1914, **15**, 50—51.

THE value of the calcined slime is increased by emulsifying any "white precipitate" present before treatment with acid, thus avoiding the formation of difficultly-soluble, "greasy" lumps; and by heating the slime for at least 12 hrs. with excess of acid and then neutralising the excess with part of the coarser zinc shavings: sodium bisulphate is more economical than sulphuric acid and is now generally used. The life of the clay liner (of a pot used for smelting) is prolonged by filling the space between the liner and the pot with powdered graphite (crushed pots): fusion is facilitated and a slag obtained containing less than 10 oz. Au per ton (after panning) by covering (not mixing) the charge of calcined slime with 15—20% of its weight of a mixture of calcined borax 1, and fine sand 1½, parts by weight.—W. E. F. P.

Gold; Method of determining —— in by-products containing platinum and iridium, etc. H. R. Jolly. J. Chem., Met., and Min. Soc., S. Africa, 1914, **15**, 51—52.

THE bead obtained by cupelling the lead button from the pot assay is heated with dilute *aqua regia* (1 : 1) until all the gold is dissolved, the solution filtered, neutralised with sodium hydroxide, warmed, treated with 5—8 c.c. of warm potassium cyanide solution and in 10 mins. with 30 c.c. of sodium sulphite solution (20%), warmed for 10—15 mins., then diluted to about 300 c.c. The following solutions are added in the order given with constant stirring: 8—10 drops of potassium ferrocyanide (10%), 30 c.c. of copper sulphate (20%), 30 c.c. of sulphuric acid (20%), and 10 c.c. of sodium sulphite. The precipitate is allowed to settle, filtered off and treated by the ordinary pot assay process, the resulting bead being parted as usual. In five experiments in which from 5 to 17 mgrms. of check gold were dissolved in *aqua regia*, 99·8—100% of the Au was recovered by this process.—W. E. F. P.

Nickel-copper-gold-silver alloys; Quaternary mixtures with two liquid strata and the quaternary ——. Equilibria in quaternary systems. N. Parravano. Gazz. chim. ital., 1914, **44**, II., 279—349. (See also this J., 1913, 1112, 1158; 1914, 261.)

THE equilibrium which regulates the separation of the pure components, or of binary, ternary, or quaternary solid solutions from quaternary mixtures with two liquid strata is discussed; and such systems are divided into 7 types, for each of which are given the nature of the boundaries of the space which limits the primary separation of a pure component; the surface which limits the secondary separation of a pure component; the curve which defines the tertiary separation of a pure component; and the spaces which define the primary separation of binary, ternary, and quaternary solid solutions respectively. A re-investigation of ternary Cu-Au-Ag alloys gave results agreeing on the whole with those obtained by Jänecke (this J., 1911, 1259). The temperatures of initial separation of one component and of two components, and of complete solidification were determined for 276 quaternary alloys. The zones of coexistence of the solid and liquid phases and the zones of solid miscibility are shown on tetrahedral diagrams. In addition to these, a series of triangular diagrams depict the isotherms in the separation of solid solutions of varying composition, when in each case, the quantity of nickel in the liquid remains constant at a definite percentage. The structure of the alloys obtained was also examined micrographically, and it was possible to recognise crystals of pure metals, solid solutions, and eutectics, also to distinguish primary from secondary constituents.—J. N. P.

Plant of New Jersey Zinc Company. Oil, Paint and Drug Rep., Nov. 2, 1914. [T.R.]

LECLAIRE'S process of making zinc oxide by distilling and burning metallic zinc, started between 1840 and 1850, is still in use in Europe and at the Florence works of the New Jersey Zinc Company of Pennsylvania. In 1848 the New Jersey Zinc Company began experimenting at Newark, and in 1850 built its first works. Originally it intended to make metallic zinc, but found that the Franklin ores contained too much iron and manganese to make this profitable, and therefore turned its attention to the manufacture of oxide. It experimented with various processes, and finally adopted the one which is now in use, which was patented in 1852.

The Palmerton plant occupies a long, narrow strip of land in the Lehigh valley, extending westward from Palmerton about one and three-quarter miles. On this plot the company has a large oxide plant and also plants for the manufacture of spiegeleisen, zinc, lithopone, and sulphuric acid. By 1910 the business had outgrown the location and a second plant was built, to the east of the town.

The ore is all obtained from the mines at Franklin Furnace, N.J., where it is crushed and treated, first by magnetic separators and then by jigs, which separate it into four products. The first, called Franklinite, consists mainly of oxides of zinc, iron, and manganese, with practically no injurious impurities. This ore is worked by itself, making the best qualities of oxide. The residue remaining in the furnaces after removal of the zinc is taken to the blast furnaces for the manufacture of spiegeleisen. The second product contains about the same amount of zinc as Franklinite, but less iron and manganese, and does not make quite as good an oxide. It is used, like Franklinite, for the manufacture of oxide, and the residues are thrown away. The third product is Willemite, or anhydrous zinc silicate, free from cadmium and almost free from lead, which is used for the production of pure commercial zinc. This is used for making brass and other alloys that are to be spun and drawn, as the metal made with it is ductile and not liable to crack when worked; also for galvanising telegraph and telephone wires which have to stand severe bending in making the splices, as it has been found that a coating of pure zinc free from lead and cadimum is less likely to crack and peel off than if a less pure material is used. The fourth product from the ore at Franklin is limestone tailings.

The ores are shipped to Palmerton, where they are received on a high trestle, parallel to the furnace rooms. Here they are dumped in bins or stocked in large piles behind the trestle, from which they can be returned to the bins by a gantry crane. The coal is brought in on the same trestle and placed in bins in line with the ore bins. From the bins the ore and coal are drawn into a car which takes them to the mixers, where they are weighed in proper proportions, mixed by machinery and elevated to bins over the furnaces. From these they are drawn in weighed amounts into hoppers on travelling cranes which deliver them to the different furnaces.

In the west plant at Palmerton there are 34 blocks of furnaces, and in the east plant 20 blocks. Each furnace is a brick chamber with an arched roof and a flat grate, under which is a closed ashpit. The total grate surface of the furnaces is about one-half acre.

A new furnace is first heated and then a thin layer of coal is spread on the grate and ignited. When this is burning well a charge of mixed ore and coal is dropped on it. A blast is blown into the closed ashpit, and passes up through the charge, burning the coal and reducing and volatilising the zinc, which is burned by the excess of air above the charge. The zinc oxide so produced and the products of combustion are drawn from the furnace by large exhaust fans which blow them over to the bag-rooms. The bag-rooms have a system of distributing pipes at the top, from which hang muslin bags about 45 feet long and 6 feet in circumference. The combustion gases pass out through the bags and the oxide is collected in them. The bags are connected with hoppers at the bottom, from which the finished oxide is drawn to be taken to the packing room. The six bag-rooms in the two plants contain nearly 71 miles of bags, with a total surface of 51¼ acres of muslin. The oxide is first bolted through wire screens. Each bolting machine feeds into a packer which forces the oxide into barrels or bags. The barrels are made at the plant and contain 300 lb. of oxide each. The paper bags contain 50 lb. each.

Zinc-silver-lead alloys; Ternary ——. B. Bogitch. Compt. rend., 1914, **159**, 178—180. J. Chem. Soc., 1914, **106**, ii., 729.

ON melting together lead, silver, and zinc, two layers are generally formed, and the author has studied the distribution of the three metals between the two layers at the temperature of solidification of the top layer, this being the poorer in lead, and consequently less fusible. Some twenty fused mixtures were studied, and a curve is given showing the proportions of the three metals which give two layers, and those which can exist without liquation. These results only hold good for temperatures near to the solidification point.

Copper, lead, and nickel; Reduction of the oxides of ——. P. Sabatier and L. Espil. Comptes rend., 1914, **159**, 137—142. J. Chem. Soc., 1914, **106**, ii., 729—730.

COPPER oxide is reduced to metal without the intermediate formation of cuprous oxide, by dry hydrogen at 150° C. The curve showing the rate of reduction is formed by one branch only, the velocity being small at first, then increasing rapidly up to a certain point, after which it diminishes regularly. This oxide is reduced directly to the metal.

The reduction of lead peroxide by a stream of dry hydrogen is first manifest at 150° C., it being reduced to the protoxide without the intermediate formation of red lead (compare Glaser, this J., 1903, 1051). The protoxide, litharge, is first visible at 190° C., it being slowly transformed at this temperature, and more rapidly at 240° C. into the suboxide, Pb_2O, this oxide being, in its turn, slowly reduced to metallic lead at 250°, and rapidly at 300° C.

The authors have repeated their work, already described (this J., 1914, 351), on the reduction of nickel oxide, and maintain their opinion that the unstable, intermediate suboxide formed has the composition Ni_4O, and not Ni_2O as given by Berger (this J., 1914, 752).

[*Copper smelting.*] *Coal-dust firing for reverberatory furnaces.* E. P. Mathewson. Eng. and Min. J., 1914, **98**, 725—727.

As a result of successful trials, all the reverberatory furnaces for smelting copper matte at Garfield and at Anaconda, Mont., U.S.A., will be fitted for firing with coal dust, and at Anaconda a new furnace with an estimated capacity of 800 tons daily is being designed. Coal-dust firing was first used successfully by D. H. Browne at Copper Cliff, Ont., Canada, for smelting basic ore, and preliminary drying and very fine pulverisation of the coal were found to be essential. The plant consisted of a Ruggles-Coles dryer and Raymond pulveriser, Sturtevant fans, a centrifugal separator, and screw conveying machinery for the coal dust. The charge was dropped through holes in the furnace roof along the sides. At Garfield with Western (U.S.A.) ores, according to W. J. Leonard, one furnace, which was not rebuilt, smelted about 400 tons of ore daily, using 14·5% coal. The slag averaged SiO_2 42, FeO 38, and CaO 13%. The coal contained moisture 7, ash 6, volatile combustible matter 46, and fixed carbon 48%, with a calorific value of 13,500 B.T.U. when dry. At Anaconda in a furnace, which was rebuilt and provided with hoppers along both sides, down the middle and across the firing end, 475 tons of ore were smelted daily with a coal consumption of 13·8%. Tables of smelting results are given. With this method of charging, the side walls are protected by the charge, thus rendering fettling unnecessary and there is no appreciable bath of molten matte. The matte is tapped at the front of the furnace instead of at the side.—W. F. F.

Copper and the war. Engineering, Nov. 13, 1914. [T.R.]

The world's production and consumption of copper have been seriously interfered with by the war, and prices are very unreliable. The world's production of copper during recent years has been as follows :—1913, 1,005,900 tons; 1912, 1,018,600 tons; 1911, 893,800 tons; 1910, 891,000 tons. More than 50 per cent. of the total is produced in the United States—last year 589,100 tons out of 1,005,900 tons. Copper was also produced last year in the following countries :—Mexico, 90,000 tons; Japan, 77,200 tons; and Australia, 41,800 tons. As regards Europe, German and Austrian output was 52,100 tons, out of a total European output of 186,500 tons. Great Britain is second, with 41,100 tons; then Russia, 34,300 tons; and Spain with 23,600 tons. European consumption during 1913 reached 643,100 tons; after allowing for the European output, 456,600 tons had to be imported, obviously mainly from America. The European consumption was :—Germany, 259,300 tons; Great Britain, 140,300 tons; France, 103,600 tons; Russia, 40,200 tons; Austria, 37,200 tons; Italy, 31,200 tons. The American consumption was 351,000 tons. Reduced consumption has necessarily resulted in reduced production; the world's copper output, now that curtailment has become effective, has dropped to a basis of about 550,000 tons per annum. At the great Rio Tinto copper mine in Spain operations have been slowing down; its operations are said to have been curtailed to bring it in line with orders issued by other companies. It may be assumed that the leading copper mines of Germany, if not entirely closed down, have also curtailed their production, as the two leading consumers of copper in that country have been idle for some weeks. The Russian output is entirely required by Russian consumers, the Austrian output is unimportant, and the Italian output, 1600 tons, is very insignificant, whilst the Scandinavian output is only 12,000 tons. The Australian output has been reduced 50 per cent., Chili has drastically cut down production, the output last year having been 30,385 tons. The Peruvian output has been cut down 50 per cent., Mexican output is reduced to a nominal quantity, and the Canadian output is also cut down.

Although the output of ore was stopped as soon as possible after the outbreak of war, the output of the smelting and refining works cannot show a similar decrease until the materials in the vats have been withdrawn; ninety days must be allowed for that. After peace has been proclaimed, three months must elapse before normal refinery supplies can again be obtained. The total American exports for October have been estimated at about 16,200 tons, and for September, 16,838 tons and August, 19,676 tons: the average exports from 1910 to 1913 during August and September have been 30,000 and 29,300 tons, respectively.

Towards the end of September the British Government acquired all the stocks of copper in Dutch warehouses, this metal being mostly destined for Germany. Three cargoes of copper afloat for Holland were also taken by the British Government. As a result the export of copper from the United States is restricted, as shipments can only be made with impunity to Great Britain, France, Italy, and Roumania, and not to the Scandinavian countries and Holland. Germany imports annually over 200,000 tons of copper; a prolonged war might result in a copper famine.

The total value of the American copper exports may be taken at £30,000,000, all of which come to European countries, except about £1,458,000 worth, which were sent mainly to Canada.

British exports and imports of copper occur as ore, unwrought bars, blocks, slabs, cakes, and ingots, and copper goods manufactured. Our total copper exports of all varieties are :—

	Tons.	£
1909	40,440	2,745,300
1910	50,210	3,340,000
1911	50,300	3,374,300
1912	43,040	2,901,200
1913	53,200	4,180,400

Our total imports have been :—

	Tons.	£
1909	288,430	11,569,200
1910	237,950	9,295,800
1911	263,740	9,355,300
1912	251,650	11,029,200
1913	257,620	11,312,000

The world's consumption of copper has been as follows, in tons :—

—	1913.	1912.	1911.	1910.
England	140,300	148,877	159,736	148,187
France	103,600	106,753	106,408	92,838
Russia	40,200	38,818	31,830	28,237
Germany	259,300	253,429	234,985	208,826
Austria	37,200	51,574	41,101	37,150
Italy	31,200	34,378	40,949	32,487
United States	351,000	365,922	316,791	334,565

German silver; Metallography of ——. F. C. Thompson. Chem. Soc. Trans., 1914, **105**, 2342—2349.

The preparation of a satisfactory alloy involves the reduction of the cored crystals, which are very persistent in nickeliferous alloys after casting, and which impart brittleness to the metal, to a structure consisting of allotrimorphic crystals. With the help of micrographs, the influence of physical treatment, such as annealing, and of the chemical composition, on the properties of Cu-Zn-Ni alloys was studied. Metal which had been overheated during the annealing was made brittle through the re-formation of the large cored crystals which are obtained after casting. This fault could be rectified by re-annealing at a lower temperature, which caused a transformation in the crystal structure and a removal of all dendritic markings. The improvement in the tensile strength of the metal resulting from the reduction of the crystal grains is attributed to a cementing action of intercrystalline boundaries. Nickel played an important part in reducing the size of the grains, the effect being proportional to the amount present. Any oxygen in the alloy was attributed to finely disseminated zinc oxide. The addition of manganese as a deoxidant caused a notable reduction in the size of the crystals in the case of Muntz metal, and to a smaller extent with German silver. Lead present in German silver separates out as a distinct insoluble component in globular form, and tin combines with the copper and separates in a similar manner.

The properties of German silver show a number of analogies to those of steel, *e.g.*, in regard to the process of annealing, the influence of metals added, and the phenomenon of recrystallisation after cold working.—J. N. P.

Bearing metals; Investigations on ——. E. Heyn and O. Bauer. Verh. Ver. Bef. Gewerbfl. 1914, Beiheft, March 30; Chem.-Techn. Rep., 1914, **38**, 232.

Curves and data are given correlating the composition of Pb-Sn-Sb alloys with the temperature of incipient solidification, somewhat below the pouring temperature, and the temperature of complete solidification, which is the upper limit at which the bearing can be run. In general there is a considerable interval between these temperatures. Alloys containing less than 25% Sb show a tendency to segregation with rising tin-content and require rapid cooling; 2—3% Cu diminishes this, and renders the alloy harder and more brittle. The hardest alloy contains Sn 30, Sb 60, Pb 10%. The hardness of each binary alloy is increased by the addition of the third metal. Hardness is usually accompanied by brittleness, but although alloys rich in tin (up to 84%) and containing less than 25% Sb are hard they are not broken by a sudden blow; their behaviour under compression is normal.—O. E. M.

Lead; Corrosion of ——. R. H. Gaines. J. Ind. Eng. Chem., 1913, **5**, 766—768.

Lead is corroded by lime mortar, lime putty and lime water. Lead immersed in alkaline water that had leaked through concrete lost 0·132% in 8 days. Several cases of the corrosion of lead service pipes in wet concrete were observed, where there was no evidence of leakage of electricity. Samples of manganese bronze, steel, lead, copper and Monel metal were embedded singly and in contact in damp concrete, and the loss in weight determined after 2 months. With the exception of lead (loss=11·99 grms. per sq. ft.) the corrosion loss was very small, and that of Monel metal almost *nil*. The losses of the metals in contact differed but slightly from those observed with the metals alone. The corrosion of lead in soil is not always negligible, even in the absence of stray currents. In some soils lead pipes are destroyed by electrolysis more rapidly than steel pipes. At St. Paul, U.S.A., lead water pipes were damaged by the current escaping from electric railway lines, whilst cast iron pipes in the line of the same current were but little affected by corrosion.—C. A. M.

Alloys; The specific heat of metallic ——. Saposhnikow. Int. Zeits. Metallog., 1914, **6**, 114—115.

The specific heat of the alloys of Bi-Cd, Sb-Sn, Bi-Sb, and Zn-Sb, were determined between 15° and 100° C. in the water calorimeter. The results obtained are in close agreement with the values calculated on the assumption that specific heat is a purely additive property.—T. St.

Nickel; Polymorphic change in ——. Baikow. Int. Zeits. Metallog., 1914, **6**, 115.

A cooling curve of nickel heated in a vertical electric furnace was obtained, temperatures and temperature-differences being simultaneously registered photographically, copper being used as the neutral body. A slight break was obtained on the difference curve at 360° C., agreeing with the known magnetic transformation of nickel at 340° C.—T. St.

Passivity of metals. H. G. Byers and S. C. Langdon. J. Amer. Chem. Soc., 1914, **36**, 2004—2011.

The effect of dissolved oxygen on the time required to induce passivity in iron was studied, and it is concluded that passivity, when not associated with a visible film, is due to the rate of ionisation of the metal being insufficient to carry currents beyond a certain density, so that, in oxygen electrolytes, when such density is exceeded, oxygen electrodes, consisting of occluded oxygen, are formed. The concentration of dissolved oxygen about the anode is regarded as the most important factor in conditioning passivity (compare Byers, this J., 1908, 1160). Non-anodic passivity is likewise due to occlusion of oxygen and consequent protection of the metal from attack. With a sufficient dilution, iron as an anode may be rendered passive even in hydrochloric acid solution, the conditions favouring liberation of oxygen at the anode.—F. Sodn.

Briquetting ores and flue-dust using as binding agent the dust recovered in purifying blast-furnace gases. O. Kippe. Stahl u. Eisen, 1914, **34**, 1164—1165.

The dust recovered in the dry-cleaning of blast-furnace gases forms an excellent binding agent for the manufacture of briquettes from fine ores or flue-dust. The ore or flue-dust is mixed with 5—10% of the filter-dust, formed into briquettes, and hardened by treatment with steam at 7—10 atmospheres pressure for 6—10 hours. Briquettes prepared in this way had a crushing strength of from 93 to 153 kilos. per sq. cm., and yielded little dust when broken by being dropped from a height of 3 m on to a cast-iron plate. The strength of the briquettes was not adversely affected by heating at 300°—400° C. or at 1000°—1100° C. With certain ores, it is advisable to add 0·5—1% of lime to the filter-dust.—A. S.

Blast-furnace gases; Purifying —— *by means of water-spray and cooling.* M. A. Bayer. Rev. gén. Chim. pure et appl., 1913, **16**, 325. Chem. Tech. Rep., 1914, **38**, 79.

After passing through the dust chamber, the gases are led through a chamber in which they are treated with water spray and cooled to 40° C. The steam resulting from the water spray condenses and carries down most of the suspended dust. The gases then pass through another chamber containing water-cooled pipes to condense any aqueous vapour and thereby abstract any remaining dust.—W. F. B.

Blast-furnace slags; The influence of alumina on ——. J. E. Johnson. Ferrum, 1913, **11**, 20—25.

Alumina takes no part in the chemical reactions in a blast-furnace, its action being merely to increase the viscosity of the molten slag. This action becomes marked when the alumina amounts to about 16%, reaches a maximum at 20%, and decreases again at 25 to 30%. Whatever the amount of alumina present, the ratio of lime (lime + magnesia) to silica should be about 1·5 for basic iron and 1·2 to 1·4 for foundry iron. Indirectly, by reason of the greater viscosity of a slag containing alumina, whereby the iron is held up for a longer period and thus becomes heated to a higher temperature, the presence of alumina is favourable to the production of iron high in silicon.—T. St.

Brass, lead, and copper; Industrial diseases among workers in ——. P. M. Grempe. Gürtler-, Bijouterie- u. Metallw.-Ind., 1913, **11**, 157. Chem. Techn. Rep., 1914, **38**, 191.

Brass and lead poisoning are equally dangerous. Green stains on the teeth and blue discoloration of the gums indicate copper and lead poisoning respectively; they are frequently confused, as they have symptoms in common. Preventive measures are best.—O. E. M.

Patents.

Semi-steel; Manufacture of ——. W. Muirhead, Shettleston, Lanark. Eng. Pat 22,263, Oct. 3, 1913.

A mixture of pig-iron and an oxidising agent (hæmatite, scale, etc.), or of pig-iron and steel scrap, is melted in an open-hearth (Siemens) furnace heated by gas, and worked in the furnace till it is converted into semi-steel. (Reference is directed to Eng. Pat. 7946 of 1907; this J., 1908, 451.)—W. E. F. P.

Manganese steel; Manufacture of ——. W. Campbell, New York, J. H. Hall, High Bridge, N.J., and H. M. Howe, Bedford Station, N.Y., Assignors to Taylor-Wharton Iron and Steel Co. U.S. Pat. 1,113,539, Oct. 13, 1914; date of appl., Aug. 10, 1908.

Claim is made for an alloy-steel containing Mn less than 9% and C from "1·075% minus 0·04 of the percentage of manganese" to "1·075% plus ⅓ of the percentage of manganese." The steel is hard and ductile, practically non-magnetic, and has a homogeneous appearance when magnified to 100 diameters.—W. E. F. P.

Electroplating non-metallic objects; Improved substance for use in processes for ——. L. Waltispurger and C. A. Rivoal, Paris. Eng. Pat. 23,741, Oct. 20, 1913.

A solution of colophony in cold "white spirit" (light petroleum) to which a conductive powder, such as copper, is added, is used for producing a conductive coating on non-metallic objects.—B. N.

Metals; Cleaning —— [*electrolytically*]. A. A. Nelson, Assignor to Acme Steel Goods Co., Chicago, Ill. U.S. Pat. 1,114,635, Oct. 20, 1914; date of appl., Feb. 25, 1914.

The iron or steel is made the cathode in a bath of fused alkali hydroxide or alkali salt, and a current passed for the removal of scale or rust, the metal being afterwards cleansed in water.—B. N.

Furnaces; Melting —— *and apparatus for stirring or agitating molten material therein.* I. Hall, Birmingham. Eng. Pats. 28,345, Dec. 9, 1913, and 5197, Feb. 28, 1914.

The stirring device, which is located in the melting pot, is actuated by a lever supported on brackets on the furnace cover, and the movement of the lever is limited by a slot, in the form of an arc of a circle, fixed to the lever, and adapted to engage a stationary pin. A centrally-located valve, for regulating the pouring of the metal, is connected by a valve stem, passing through a stuffing-box in the cover, with a second lever pivoted to a bracket on the cover. The mixing device is fixed to a sleeve or the like on the valve stem, and is attached to its lever by two rods passing through stuffing-boxes disposed one on each side of the valve stem and its operating lever.—B. N.

Furnace; Electric —— [*for melting and refining metals*]. J. H. Gray, New York. U.S. Pat. 1,113,778, Oct. 13, 1914; date of appl., Aug. 21, 1913.

The oblong hearth of the furnace has tapered ends and the electrodes are disposed above the hearth so as to form an arc between each electrode and the metal. The electrodes are arranged in several groups of three each, one group at each end of the hearth, the three electrodes of each group being connected to the respective terminals of a three-phase circuit arranged in delta, so that the current passes successively down through each electrode and up through the other two electrodes of the group. The area covered by one group overlaps that covered by another group, so as to effect a uniform distribution, and permit the operation of the furnace, if desired, with only one group of electrodes.—B. N.

[*Zinc.*] *Ores; Apparatus for smelting* ——. J. A. Potter, Pueblo, Colo. U.S. Pat. 1,113,481, Oct. 13, 1914; date of appl., Dec. 23, 1912.

In the rear wall of the reduction chamber of the apparatus is a central charging opening having, upon each side, an opening communicating with a condensing and regenerating flue, and, immediately beneath, a smaller opening through which gas from an adjacent producer chamber (operated with liquid fuel) is passed so as to permeate the charge. The reduction chamber is provided with an exhaust conduit, a pipe for the supply of air under pressure, and means for connecting either of the condensing and regenerating flues with the pressure, and the other with the exhaust, conduit.—W. E. F. P.

De-tinning; Process of ——. W. Savage, Piedmont, Ala. U.S. Pat. 1,113,491, Oct. 13, 1914; date of appl., Feb. 17, 1914.

A coating of "white tin" is subjected to the action of "a slime containing tin-ammonium chloride and gray tin."—W. E. F. P.

Ores; Agglomerating fine ——. J. H. Payne, Baltimore, Md. U.S. Pats. (A) 1,114,029 and (B) 1,114,030, Oct. 20, 1914; dates of appl., Feb. 21, 1914, and April 10, 1913.

(A) The ore, containing a material amount of sulphur, is introduced continuously into the upper end of a long rotating inclined tube, and a flame of air and gaseous fuel passed into the lower end as a counter current. Sufficient air is employed for combustion of the fuel, but not sufficient for burning material quantities of the sulphur, and the ore is heated to the point of incipient fusion so as to convert the material into nodules. (B) For copper ores, rich in sulphur, silicious material is mixed with the ore to prevent complete fusion under the influence of the heat generated by the oxidation of the sulphur.—B. N.

Electrolyte for use in electrometallurgy. N. H. M. Dekker, Paris. U.S. Pat. 1,113,546, Oct. 13, 1914. Date of appl., Aug. 17, 1912.

See Eng. Pat. 17,836 of 1912; this J., 1913, 662.—T. F. B.

Zinc; Metallurgy of ——. A. L. J. Queneau, Torresdale, Assignor to Queneau Electric Zinc Furnace Co., Philadelphia. U.S. Pat. 1,114,036, Oct. 20, 1914. Date of appl., Dec. 17, 1908.

See Fr. Pat. 403,048 of 1909; this J., 1909, 1318.—T. F. B.

Magnetic separator. G. Ullrich, Assignor to F. Krupp A.-G. Grusonwerk, Magdeburg-Buckau, Germany. U.S. Pat. 1,114,071, Oct. 20, 1914. Date of appl., July 3, 1913.

See Eng. Pat. 14,426 of 1913; this J., 1914, 359.—T. F. B.

Ores; Method of heating —— *in two chambers or retorts arranged behind each other.* E. Menne, Creuzthal, Germany. U.S. Pat. 1,114,502, Oct. 20, 1914. Date of appl., July 1, 1912.

See Ger. Pat. 253,450 of 1911; this J., 1912, 1187.—T. F. B.

Muffle-furnace. E. Curran, Cardiff. U.S. Pat. 1,114,587, Oct. 20, 1914. Date of appl., March 21, 1914.

See Eng. Pat. 6165 of 1913; this J., 1914, 320.—T. F. B.

XI.—ELECTRO-CHEMISTRY.

Over-voltage. E. Newbery. Chem. Soc. Trans., 1914, **105**, 2419—2435.

Exhaustive measurements were made of the actual back E.M.F. between electrode and electrolyte during electrolysis, or the voltage which is over and above the stationary potential given by the electrode when at rest. By means of a rapidly rotating commutator, this measurement was made during a very short interval after the interruption of the electrolytic circuit. Evidence was obtained of intermediate reactions such as dehydration of ions, which take place before an ion is liberated at an electrode, and of the selective influence exerted by colloids on the separation of the different ions, thus determining the efficiency with which zinc, for instance, is separated from an acid electrolyte. Up to a certain value, increasing current density caused an increase in overvoltage, but with higher current densities, the overvoltage gradually fell and in some cases actually became negative. This effect was traced to an inductive action of the gas as it escaped in a charged condition. Confirmation was obtained of the view that ions must penetrate to a certain distance in the metal before delivering their charge. If the free element is then gaseous, its escape is hindered by the metal and this leads to the accumulation of high pressures and rupture of the surface. This action was demonstrated by means of microphotographs which show the formation of crater-form pittings on the surface of different metals after liberation of gas by electrolysis. Measurements made on the degree of ionisation of the free gas escaping after electrolysis showed a remarkable inverse relationship to overvoltage. Variation in factors such as time, nature of metal, and temperature, which influenced the overvoltage, produced a change in the inverse sense in the ionisation of the gas. The application of high gaseous pressures—up to 100 atmospheres—was without appreciable influence on the overvoltage. The results show that all earlier formulæ expressing the overvoltage are invalidated through omitting to take into account the different factors which have been traced in this work.—J. N. P.

Solvent properties of silver nitrate solutions. The silver voltameter. III. Lowry. *See* VII.

Production of neon and helium by the electrical discharge. Collie and others. *See* VII.

Patents.

Electrode-making machines. S. L. Casella, New York. Eng. Pat. 14,582, June 17, 1914. Under Int. Conv., July 3, 1913.

A rotating table carries four moulds for the production of electrodes, the movement of the table bringing into operation four plungers as each mould is in register, whereby the following operations are carried out successively: compression of the depolarising material; perforation, axially, of the compressed material; insertion of an electrode in the perforation: and ejection of the completed electrode. The table is rotated a step after each operation, locked, and released for the next forward movement. An intermittent feed device supplies electrode material from a hopper.—B. N.

Batteries; Plates for electrical or secondary —— or accumulators. E. Hancock and D. David, Cardiff, Glamorgan. Eng. Pat. 19,109, Aug. 22, 1913.

An oxide of lead, such as litharge, is mixed to a paste with sulphuric acid and substances rich in carbohydrates or free carbon, such as potatoes. This is moulded into plates, and heated in a receptacle from which air is excluded by surrounding the plates with wood charcoal. The burnt plates are ground and the material mixed with part of the original mixture, or a similar mixture prepared from red lead, then dried and finely powdered and sulphuric acid added to form a paste. The latter is moulded into plates, which are wrapped in paper before being placed in charcoal and heated. The plates are then short-circuited between zinc or iron plates in acid, and afterwards placed between positive electrodes in acid, being then alternately charged and discharged until all impurities are extracted.—B. N.

Cell; Electrolytic ——. H. C. Jenkins, H. F. Pattinson, and R. Wellesley, London. Eng. Pat. 25,415, Nov. 6, 1913.

The liquid is introduced into the bell containing the anode, so as to maintain a concentrated condition at the anode, and liquid is displaced either upwards to a draw-off device within the bell, from which the liquid is passed to a tank with an adjustable weir, or downwards towards the lower edge of the bell. By means of suction, different levels are maintained inside and outside the bell, the liquid being drawn off at the higher level, and returned by a pipe below the level of the liquid. The gas is drawn off under suction from the interior of the bell through a pipe with a valve, the latter closing automatically when the bell is removed from the cell.—B. N.

Conductors; Electrical ——. T. B. Allen and L. B. Coulter, Assignors to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,114,665, Oct. 20, 1914; date of appl., Nov. 21, 1911.

A porous article of silicon carbide is impregnated with a colloidal solution of graphite and heated.—B. N.

Furnace; Electric —— for fixing nitrogen from the air. E. K. Scott, Belvedere. U.S. Pat. 1,113,376, Oct. 13, 1914. Date of appl., June 25, 1913.

See Eng. Pat. 14,871 of 1912; this J., 1913, 872.—T. F. B.

Electrodes for secondary batteries; Process of making ——. J. Apoznanski, Assignor to Stanislaw and Georgij Gaszynski Bros., Apoznanski & Co, Moscow. U.S. Pat. 1,114,667, Oct. 20, 1914. Date of appl., Dec. 14, 1910.

See Ger. Pat. 275,881 of 1910; this J., 1914, 971.—T. F. B.

Thermo-element. Ger. Pat. 276,354. *See* XXIII.

XII.—FATS; OILS; WAXES.

Coconut; The —— and its products, with special reference to Ceylon. D. S. Pratt. Phillip. J. Sci., 1914, **9**, 177—198.

The average palm produces about 40 nuts per annum, or upwards of 60 in well-kept plantations. There are about 750,000 acres of plantations in Ceylon, producing about 1,250 million nuts a year, of which 2 million are used daily for food, and the remainder exported as copra, etc. In 1913 the price of good nuts in Ceylon ranged from 40 to 56 pesos (83s. 4d. to 116s. 8d.) per 1000. In 1911 about 142,774 acres were under cultivation in the Malay States, the yield of copra from which was estimated at 65,600 tons. The value of the coconuts imported into the United States has risen from 1,816,484 pesos (£189,217) in 1903 to 3,562,754 pesos (£371,120) in 1913. The native method of preparing the copra is to cut the nut in two and expose the two halves on dry sandy ground for about 2 days, when the pulp is separated and the drying completed in 4 days. Artificially dried copra is inferior in colour and appearance to the sun-dried product. The method used is to place the copra on a platform of areca palm laths over an earth pit in which is a fire of dry coconut shells. About 50 kilos. of copra are prepared from 170 to 200 nuts (according to the rate of drying). Rapid drying in a current of air (*e.g.* in 10 hours) is attended with considerable loss of oil, about 15% more kernel being required to produce a given weight of copra. It should be possible to complete the drying within 72 hours by means of a slow current of air at 54° to 60° C., and with a minimum loss of oil. Ceylon copra is graded into the four qualities—*kalpentyn* (the best produced,) *estate*, *maravila* (ordinary), and *common* or *cart*, which is bought in lots from various small producers. In 1913 the *kalpentyn* grade fetched 259 pesos (£29 10s.) and *cart* 232 to 253 pesos (£24 3s. to £26 17s.) per ton. In the Phillippines the best quality is known as "Samar sun-dried," the bulk of which is used locally for the production of oil; "Cebu sun-dried," "F.M.M." (fair merchantable Manila); and "Laguna," which is frequently made from green nuts and dried over a smoky fire and readily becomes mouldy. Ceylon copra is quoted at about 20 pesos (41s. 8d.) per ton less than Cochin and Malabar copra. The total exports of copra from Ceylon in 1913 were 57,705 tons, of which 40,314 tons were sent to Germany, 12,094 tons to Russia and 1650 tons to the United Kingdom. The total imports of coconut oil into this country in 1913 were:—Refined oil, 30,087, and unrefined oil 31,559 tons. During 1911—1912 India exported 2,165,103 galls. of coconut oil valued at 2,626,876 pesos (£273,632), of which Germany took 584,251 galls. and the United States 477,487 galls. The total exports for 1912—1913 were much lower. In Ceylon it is estimated that 40 full-grown coconuts will yield 1 gall. of oil. The machinery used is primitive and relatively little oil is now expressed there. The copra is cut up, ground to a coarse bran, and heated in steam-jacketed vessels at a uniform temperature. The warm mass is then gradually pressed in a hydraulic press up to a pressure of 2 tons, until all but about 10% of oil is expelled, when the mass is again ground, rolled, heated and submitted to a pressure of 3 tons, which reduces the oil-content to about 6%. In this way about 66% of oil and 33% of oil-cake (*poonac*) are obtained, the latter being exported as a feeding stuff or ground up with phosphates, nitrates, etc. and used as a fertiliser on the coconut estates.

Desiccated coconut:—The shells of selected nuts are chipped away and the kernels shaved by hand, washed, shredded or granulated by machinery, and dried in a desiccating machine through which is driven a current of air at 82° to 93° C., whereby the moisture is reduced to the allowable maximum of 1·5 to 2%. Finally the product is sifted mechanically into fine, medium and coarse grades, cooled on zinc-covered tables, and packed in lead-lined chests, each holding about 59 kilos. It is estimated that the coconut loses about 50% in weight during desiccation, and 1000 nuts yield about 150 to 173 kilos. (according to the district). Nearly twice as many Malabar coconuts are required to produce the same amount of product as Ceylon nuts, whilst Indian nuts are dearer; hence Southern India has been unable to compete with Ceylon in the industry. The whole of the product is exported, the total exports in 1913 being 15,326 tons, of which the United Kingdom received 6339 tons, Germany 2302 tons, and the United States 3787 tons. The estimated cost of a plant to deal with 90 tons of desiccated coconuts per year is 78,520 pesos (£8179).

Coir fibre.—The best fibre is made by native methods, especially in the Galle district. The husks are placed in bamboo enclosures which are submerged in river or sea water. After about 6 days' softening they are beaten on a block, and the separated fibre hackled with a wooden comb and dried. Two classes of fibre are thus obtained, viz., "*bristle fibre*" (averaging 30 cm. in length) and "*mattress fibre*," which is spun into "coir yarn" about 17 m. long and 40 mm. thick. In the mills the fibre is softened in large tanks, iron rails being used to keep the husks submerged. After 5 days' soaking the material is crushed in a "breaker," and the fibres separated by revolving iron wheels ("drums") studded with spikes. The long coarse fibres are hackled by hand, made into hanks and partially bleached with sulphur fumes. This is made into brushes, etc. The mattress fibre, consisting of torn and broken pieces falling from the spikes of the "drums," is spun into coir yarn, and made into mats and coarse cloths, which are frequently dyed with aniline dye-stuffs. Ceylon coir yarn is sold in the two grades of *Kogalla* and *Colombo*, which are further subdivided into 15 to 24 standards differing in thickness, colour, twist, etc. The exporters' prices range from about 146 to 290 pesos (£15 4s. to £30 4s.) per ton. It is estimated that 1000 coconut husks will produce 30 to 35 kilos. of bristle fibre and about 140 kilos. of mattress fibre and yarn. The amounts of coir yarn and bristle and mattress fibres exported from Ceylon in 1913 were 5762 and 12,852 tons respectively. *Other products.*—The dry shells are burned to charcoal in pits or are destructively distilled to obtain a pyroligneous liquor which is used in coagulating rubber latex. The charcoal is excellent and is in increasing demand.—C. A. M.

Hydrogenated fats. A. E. Sandelin. Teknikern, 1913, 359—361; Chem.-Techn. Rep., 1914, **38**, 321.

Results obtained on the examination of hydrogenated products prepared from whale oil at a factory in Kaipiais, Finland, and also of hydrogenated whale oil, made in Germany and offered to a Finnish margarine factory, were:—

—W. P. S.

Chaulmoogra oil: Source of genuine ——. E. E. Francis. J. Pharm. Chim., 1914, **9**, 388—390.

Up to 1900 chaulmoogra oil was supposed to be derived from the seeds of *Gynocardia odorata*, but it was then shown to be derived from the seeds of *Taraktogenos Kurzii*, and this was generally accepted as the source of the genuine oil although the oil was still called *oleum gynocardium*. *Taraktogenos Kurzii* grows in Burmah, the Chittagong Hill Tracts and in Assam. The crop is uncertain and sometimes entirely fails and this has led to the substitution of the oil from the seeds of *Hydnocarpus Wightiana*, a tree of the same family, for the genuine oil. Since 1913 the oil derived from this latter source (also known as kavatel oil) has been fraudulently sold as genuine chaulmoogra oil although it is considerably cheaper and inferior in its dermatological effect. The two oils have a similar appearance and constitution but differ in smell, the genuine oil also containing much more free fatty acids.—T. C.

Oil of manketti nuts. H. Sprinkmeyer and A. Diedrichs. Z. Unters. Nahr. Genussm., 1914, **27**, 113—119.

The kernels of manketti nuts (*Ricinodendron rautanenii*, Schinz) from German South West Africa (8·33% of the fruit) had the following composition:—Water, 4·70; ether extract, 59·40; proteins, 26·95; ash, 3·02; and crude fibre and N-free extractives, 5·93%. The cold-drawn oil had the following characters:—Sp. gr. at 15° C., 0·9306; refraction at 40° C., about 84; at 25° C., about 93; iodine value (Hübl), 128·5; acid value, 1·25; saponif. value, 193·3; Reichert-Meissl value, 0·75; Polenske value, 0·40; Hehner value, 94·85; *Fatty acids*:—m.pt. 39·0° C.; solidif. pt. 35·7° C.; refraction at 40° C., about 69; neutralisation value, 204·5; iodine value

135·7; and mean mol. weight, 281. The oil yielded no insoluble bromide, but the fatty acids yielded linolic tetrabromide (m.pt. 114·2° C.). No destinctive colorations were obtained in the tests of Bellier, Halphen and Baudouin. In Livache's absorption test the increase in weight was 10·05%. Mixed with driers it yielded a varnish which dried more slowly than linseed oil varnish, but was superior in tenacity, freedom from stickiness, and resistance to water and alkaline liquids. The oil is thus well suited for the manufacture of linoleum. The oil-cake is rich in protein and should make a good feeding-stuff, provided no injurious constituents (such as frequently occur in seeds of *Euphorbiaceae*) are present. Physiological experiments with the oil itself were satisfactory (see also this J., 1913, 95, 611).—C. A. M.

Mabula pansa [*owala*] *seeds and oil.* H. Wagner and J. Muesmann. Z. Unters. Nahr. Genussm., 1914, **27**, 124—131.

OWALA or pauco nuts (*Pentaclethira macrophylla*) from German W. Africa contained 81% of kernels, which when air-dried had the following composition:—Water, 7·48; ash, 2·23; phosphoric acid, 0·45; crude fibre, 4·71; nitrogen, 4·68; and fat, 49·8%. The crude oil, which had a pungent taste, had the following characters:—Sp. gr. at 15° C., 0·9164; refractometer reading, 56·6; acid value, 20·4; saponification value, 181·9; iodine value, 99·5; Reichert-Meissl value, 6·5; Polenske value, 0·5; acetyl value, 20·6. *Fatty acids*:—M.pt., 56·5—57·5° C.; solidif. pt., 55·2° C.; neutralisation value, 185·7; iodine value, 106·3; iodine value of liquid fatty acids, 143·5—144·1; and mean mol. weight, 143·5—144·1. After refining with alkali the oil showed an iodine value of 101·2 and acid value, 0·3, but still had a slight bitter taste. The fatty acids contained about 25% (calculated on the oil) of lignoceric acid (m.pt. 80·5° to 81° C.) and about 43% of liquid fatty acids. The unsaponifiable matter (0·62%) contained 0·21% phytosterol (m.pt. 140·8° C.). No colorations were obtained in the tests of Baudouin, Soltsien or Halphen, but Bellier's test gave a greenish-black coloration changing to red-brown. In the elaidin test the oil solidified after some time. No insoluble bromide was obtained. (See also this J., 1906, 893; 1907, 699; 1910, 1019.)—C. A. M.

Seed oils; Characters of certain little-known ——. A. Diedrichs. Z. Unters. Nahr. Genussm., 1914, **27**, 132—141.

(1) *Date stone oil*:—Algerian date stones (11·17% H_2O) yielded 7·98% of a fairly viscous oil with a pungent taste. Bellier's reagent for vegetable oils gave no coloration. The fatty acids yielded linolic tetrabromide. (2) *Orange and lemon pip kernels* yielded 57·31 and 49·67% respectively, of light yellow oils with intense bitter taste. The orange seed oil contained linolic and linolenic acids. (3) *Bassia butyracea seeds* yielded 55·90% of a fat, which gave an insoluble bromide. The extraction-residue, on treatment with water yielded 38·3% (14·90% on original substance) of a resinous extract containing saponin. (4) *Stillingia seed*:—After separation of the fat (*Stillingia tallow*) surrounding the kernels, the latter yielded 62·03% of light yellow oil with a nutty odour and taste. The oil yielded 20·04% of insoluble bromide (m.pt. 147° C.), whereas the tallow gave no precipitate with bromine. (5) *Calotropis* (*akoon*) *seeds* from *Asclepias gigantea* contained 57·68% of kernels, and the whole seed yielded 26·76% of a viscous olive-green oil with a bitter taste and pungent odour. It gave 0·2% of an insoluble bluish-white bromide, and in Livache's test absorbed 3·98% oxygen in 10 days. The plants contained a bitter milky juice, with an odour of opium, which is used medicinally by the natives. The following characters were shown by these oils:—

—C. A. M.

Chinese or Stillingia-tallow. A. Diedrichs. Z. Unters. Nahr. u. Genussm., Aug. 15, 1914.

STILLINGIA-TALLOW, or "vegetable tallow," is exported from China in large quantity for making soap and candles. It is an interesting peculiarity of this fat that, when congealing, it expands with great force, so that a thin glass is usually ruptured. It is not impossible to use it, when sufficiently purified, for nourishment. The fat is imported as such and not the seed. It is said to be often adulterated by the Chinese. Even in a purified condition it soon becomes bitter in taste, and of a disagreeable odour.

Waste products [*oils and greases*]; *Reclamation of* —— [*from cotton waste, etc. used for cleaning machinery*]. G. H. Ayres. Times Eng. Suppl., Oct. 30, 1914, 128.

OILY waste or rag is placed in a centrifugal separator driven directly by a steam turbine forming an integral part of the machine, the exhaust steam serving to heat and liquefy the oil and grease. The separated oil is purified by settling or filtration. The waste or rag is then washed and dried. Sponge cloths used instead of cotton waste on the Lancashire and Yorkshire Railway yield 1—1¼ gall. oil per gross. Similar methods are employed for the recovery of "cutting oil" from metal screwings and turnings, turpentine and ink from the cleaning materials used in printing works, wax and composition from the short ends and waste in candle and match factories, and fats in cocoa, chocolate and biscuit factories and bakeries.—A. T. L.

Beeswax; Bleaching of ——. K. Heinz. Seifensied Zeit., 1913, **40**, 1140, 1169, 1192. Chem.-Techn. Rep. 1914, **38**, 132.

COMPLETE bleaching of beeswax can only be effected b sunlight, and all chemical methods require supple menting by sun-bleaching for the production o absolutely white wax. Moreover, it is frequently impossible to remove all traces of chemicals from the product Natural bleaching is effected by repeated exposures the wax being melted with water containing sulphuric aci between each exposure. Of chemical agents, oil of turpentine has the drawback of imparting an unpleasant odou to the wax. It is preferable to add to the water, used t prevent overheating of the wax by the sun, potassium chlorate, sodium hypochlorite, or hydrogen peroxide. Another method is to boil 100 kilos. of the melted wax with a solution of 3 kilos. of potassium chlorate in 10 litres of water acidified with sulphuric acid, and after removal of the chemicals, to finish the bleaching in the sun. Permanganate is not effective as a bleaching agent. One of the best methods is to boil the wax with a solution of potassium bichromate and sulphuric acid, and to remove the chromic oxide by washing with water containing lactic or sulphuric acid. Ozone has not proved very effective. Bleaching with fuller's earth, Florida earth, and the like, has the drawback that the powder retains a considerable amount of wax, which can only be recovered by extraction.—C. A. M.

Rosin; Determination of —— in fats and soaps. Leiste and C. Stiepel. Seifensieder-Zeit., 1913, **40**, 1233. Chem. Techn. Rep., 1914, **38**, 213.

The fat or soap is dissolved in alcohol, neutralised with alcoholic soda, and the mass obtained on evaporating the solution in admixture with a quantity of freshly ignited sand is extracted with acetone containing 2% of water. The rosin and unsaponifiable matter are extracted together, but since the latter is present in the ordinary soap-making fats to a slight extent only its amount may be neglected. —J. A.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Enamel paints. O. M. Meissl. Oesterr. Woch. öffentl. Baudienst, 1913, [15]. Chem. Techn. Rep., 1914, **38**, 94.

The chief requisite of a good enamel is durability. The drying medium of ordinary enamels is linseed oil and its substitutes. The addition of rosin oil makes the enamel liable to crack and to become sticky in the sun, whilst mineral oils retard the drying, and driers reduce the stability to the same extent as they accelerate drying. The function of the drying medium does not cease with the drying of the enamel, but promotes subsequent oxidation. For outside work enamels should be as free as possible from driers and diluting liquids such as oil of turpentine, petroleum spirit, etc. Direct sunlight and moisture have a great influence on the stability. Zinc pigments are less durable than iron and lead pigments out-of-doors, but for interior work zinc and iron pigments are preferable to lead. For stations, locomotive sheds, etc., iron oxide pigments are preferable to red lead pigments. The durability of an enamel increases with the fineness of the pigment, whilst lighter shades of colour are less durable than dark shades. The durability of enamels for ordinary purposes increases with the elasticity of the film, whereas enamels for use under water are as a rule more durable in proportion to their hardness. The thinner the layers of pigment and the more numerous the coats, the more durable is the enamel. It ought never to be applied below 4° C. Zinc white is dearer in use than white lead, since it requires more linseed oil. No satisfactory substitute for red lead in enamels for iron work has yet been found; iron oxides have not the same durability.—C. A. M.

Turpentine oil; Detection of hydrocarbons in ——. Utz. Farbenzeit., 1912, **17**, 1208. Z. Unters. Nahr. u Genussm., 1914, **27**, 687.

Mennechet's test, in which 4—5 c.c. of oil are shaken with a little magenta and 2 drops of nitric acid, gives characteristic colorations with turpentine oil and with hydrocarbon substitutes which enable these to be readily distinguished, but is not sufficiently delicate to indicate admixture of hydrocarbons with oil of turpentine unless at least 30% of the former is present.—T. C.

Resinates; Photochemical properties of coloured ——. J. Larguier des Bancels. Compt. rend., 1914, **159**, 316—317. Chem. Soc. J., 1914, **106**, ii., 696. (Compare this J., 1912, 797.)

Coloured resinates when exposed to light slowly lose their solubility in benzene. This process is accelerated by the presence of small quantities of mineral salts. Of the chlorides and nitrates of a large number of metals tried, only those of uranium, zinc, and cadmium exert any marked influence, the effect produced being, within certain limits, proportional to the amount of active salt present. The action of uranium is much more powerful than that of zinc or cadmium, which are of the same order. To produce the same effect in the same time, the concentration of zinc or cadmium nitrates requires to be twenty times that of uranium nitrate. The results obtained with uranium and zinc salts are not due to their hydrolysis in aqueous or alcoholic solution giving an acid solution. Certain salts, such as those of copper, iron, chromium, and thorium entirely modify the properties of the resinates, rendering them insoluble, or producing a precipitation which interferes with the experiment.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

[*Rubber latex*] ; *The tapping interval of* ——. N. C. S. Bosanquet. India-Rubber J., 1914, **48**, 797—798.

Observations, extending over more than a year, on a 94-acre clearing of 7-year old rubber, demonstrated that tapping on alternate days yielded better results than more frequent tapping. The yield per tree with daily tapping varied from 2·32 grms. in October to 3·03 grms. in December, at a cost of 29 to 19 cents (5·8—3·8d.) per lb., whereas when the trees were tapped on alternate days the yield was 4·54 grms. in January and 6·75 grms. in June, the cost being 13 cents (2·6d.) in the former and 11 cents (2·2d.) in the latter month. There is a considerable saving on bark removal, on the alternate day system. —E. W. L.

Rubber ; Packing of plantation ——. P. Schidrowitz. India Rubber J., 1914, **48**, 802.

To avoid contamination with wood splinters, etc., and thus enable plantation rubber to be used without washing other than that carried out on the plantation, it is suggested that the cases should have a loose lining of cloth, of the type used in rubber works for wrapping, etc.—E. W. L.

Coconut and its products, with special reference to Ceylon. Pratt. *See* XII.

XVI.—SOILS ; FERTILISERS.

Soil ; Studies of an acid —— *in Assam.* A. A. Meggit
Memoirs Dept. Agric. India. Chemical Series, 191
Vol. 3, No. 9, 235—269.

Test crops of oats were grown at Jorhat, Assam, in a
area of 0·26 acre comprising 26 plots, each of whic
received a different manurial treatment, with and withou
liming. From the results obtained it was concluded tha
the highly beneficial effect of lime is due to its action i
neutralising acidity and destroying, or preventing undu
accumulation of, toxic material in the soil.—W. E. F. P.

Soil constituents ; Relative solubility of ——. H. Fische
Intern. Mitt. Bodenkunde, 1913, III., 331. Biede
mann's Zentr., 1914, **43**, 292—294.

The potash of biotite was found to be less soluble tha
that of phonolith in water saturated with carbon dioxid
although in culture experiments by Pfeiffer and Blanck
oats absorbed more potash from biotite than from phon
lith.—R. G. P.

Ammonia ; Volatilisation of —— *from soils.* O. Lemme
mann and L. Fresenius. Landw. Jahrb., 1913, **45**, 12
Biedermann's Zentr., 1914, **43**, 435—437.

A current of air from an air pressure apparatus was le
through three wash-bottles to saturate it with moistur
then through dilute sulphuric acid and dilute ammoni
and finally through an empty flask. It was then passe
over the soil to be tested and subsequently through N/
acid. A similar experiment was done without the soi
The absorption of ammonium salts depended upon a
exchange of the bases of zeolithic origin present in th
soil. In presence of chalk the absorption of ammonia b
the soil was increased or diminished. or remained un
affected, according to the nature and source of the soi
—J. H. J.

Nitrogen ; Absorption of different forms of —— *by plants*
influence of the medium. D. Chouchak. Compt
rend., 1913, **156**, 1784—1787. Biedermann's Zentr
1914, **43**, 409—412.

The influence of various salts upon the adsorption
nitrogen from an ammonium chloride solution by pla
roots was studied. With living plants the adsorption wa
proportional to the time, whilst the rate of diffusio
inside the roots was constant. With dead roots, ma
nesium sulphate prevented any adsorption, and sodiu
sulphate, magnesium chloride, calcium chloride, and ca
cium sulphate markedly decreased the amount in varyin
degrees. With living roots, the influence of the salts, thoug
considerable, was less than with dead roots. When two
more salts were present at the same time in varying propo
tions, the influence of one was in some cases antagonistic t
that of another, and there was a maximum concentratio
with the different mixtures above which adsorption of nitr
gen decreased. In the system, water, root, and dissolve
nitrogenous substance, the last is divided between th
water and the superficial layer of the root in certai
proportions which are easily modified by the presence
other dissolved substances, *e.g.*, the salts mentioned abov
—J. H. J.

Calcium cyanamide [*nitrolim*] *; Behaviour of some moul*
fungi towards ——. A. Kossowicz. Z. Gärungsphysiol
1913, **2**, 154. Biedermann's Zentr., 1914, **43**, 140—14

Nutrient solutions were prepared containing as sol
nitrogenous matter two commercial specimens of calciu
cyanamide previously sterilised by heating at 100°
or by filtering their solutions through a Berkfeld filte
In some of the solutions all the organisms tested, viz.
Botrytis Bassiana, *Penicillium glaucum*, *Mucor Boidi*
Cladosporium herbarum, *Phytophthora infestans*, *Penicilliu*
brevicoule, *Aspergillus glaucus* and *niger*, *Isaria farinosa* an
a red *Fusarium*, exhibited more or less growth, but in other
only the first three or five developed. The results wer
probably influenced by impurities in the calcium cyanamid

and this point may be of importance in the application of calcium cyanamide as a fertiliser.—J. H. L.

Potassium salts ; Occurrence of —— in the salt springs of the United States. J. W. Turrentine. U.S. Dept. Agric., Bureau of Soils, Bull. No. 94, May 8, 1913. Biedermann's Zentr., 1914, **43**, 403.

None of the artificial and natural brines examined was found to contain potassium in sufficient quantity to repay extraction. The mother-liquors in the preparation of salt from sea-water contain sufficient potassium to enable them to be converted into a fertiliser by evaporation. The residue of a dried-up lake in South California contained so much potassium that it would form a valuable source of potash salts on the commercial scale.—J. H. J.

Phosphoric acid in basic slag ; Determination of the —— soluble in citric acid. F. Haussding. Landw. Jahrb., 1913, **45**, 49. Biedermann's Zentr., 1914, **43**, 438—439.

The methods of von Lorenz (compare Neubauer and Lücker, this J., 1912, 259) and Popp (this J., 1912, 831 ; 1913, 953), and the official method were compared. The iron citrate method of Popp gave the highest results, nearly identical with those obtained by the official method and the direct precipitation method of von Lorenz gave rather lower but more accurate results. The adoption of the von Lorenz method would entail a rise in the price of the phosphoric acid.—J. H. J.

Phosphates ; Experiments with crude ——. Prianischnikow. Biedermann's Zentr., 1914, **43**, 395—401.

Russian phosphates used as manure in pot cultures gave increased yields of mustard, lupin, etc. A Russian phosphate containing 26% P_2O_5 was converted into a superphosphate containing 12·5—13·5% of water-soluble, 14—14·5% of citrate-soluble and 14·5—15% of total P_2O_5, at a cost of 40 centimes per kilo. of water-soluble phosphate. Extraction of various phosphates with dilute sulphuric acid showed that for each variety the quantity of phosphoric acid extracted reached a maximum, varying from 46 to 73%, with a definite quantity of acid. Sodium bisulphate may replace sulphuric acid in the preparation of superphosphate. If to the solution, milk of lime is added, the precipitate contains 22—37% P_2O_5. Nitrosuperphosphate prepared with the waste acid from the manufacture of trinitrotoluene contained higher proportions of total and water-soluble P_2O_5 than ordinary superphosphate prepared from the same raw phosphate with sulphuric acid. Small amounts of ferrous and ferric sulphates added to phosphates were beneficial in sand cultures, but larger amounts were harmful. Double phosphates were prepared by the extraction of the acid radical of the phosphate with dilute sulphuric acid or sodium bisulphate, concentrating the solution and mixing with bone meal free from gelatin ; the double phosphate contained about 25% P_2O_5 of which about 95% was soluble in water. That phosphates are assimilated by plants was proved by sand cultures of lupins and buckwheat, in which a certain proportion of the phosphate added was found in the crop.—J. H. J.

Bone-meal ; Action of —— as a phosphoric acid fertiliser in comparison with superphosphate and basic slag. B. Schulze. Landw. Versuchs-stat., 1913, **83**, 101—180. Biedermann's Zentr., 1914, **43**, 441—443.

The experiments continued over three seasons and the comparison was made between the water-soluble phosphate of superphosphate, the citric acid-soluble phosphate of basic slag, and the total phosphate of bone meal. The superphosphate gave the best results ; the basic slag being about 80% as effective, and the bone meal about 60%. Bone meal free from gelatin gave better results than that containing gelatin. The grinding of the bone meal has a great influence upon its effectiveness ; the finer the grinding, the better the manurial results. Coarsely ground meal has only about two-thirds the effect of finely ground meal.—J. H. J.

Manurial experiments with lime. P. Bolin. Meddelanden Nr. 80 fran centralanstalten for jordbruksforsok, Stockholm, 1913. Biedermann's Zentr., 1914, **43**, 112.

In experiments with oats three types of fertilisers were employed with and without lime (1·6—1·9 tons per acre), viz., 1·2 cwt. of potassium nitrate with 4·8 cwt. of basic slag and 1·6 cwt. of 37% potassium sulphate per acre ; 16—32 tons of cow dung per acre ; and 8—12 tons of cow dung with 4·8 cwt. of basic slag and 0·8 cwt. of potassium sulphate per acre. The lime reduced the crop obtained with artificial fertilisers alone, but considerably increased that obtained with the animal manure.—J. H. L.

Sulphur for stimulating plant growth. F. de Castella. J. Dep. Agric. Victoria, 1914, **12**, 289. Pharm. J., 1914, 667.

For some time the attention of agricultural chemists has been directed to the value of sulphur as a manure (this J., 1913, 669 ; 1914, 975). The author confirms the fact that it acts favourably on the growth and yield of the vine. It does not act alone, however ; its beneficial effect is directly proportional to the amount of organic matter present in the soil to which it is added. When the quantity of organic matter diminishes, the effect of sulphur also diminishes and becomes nil in a soil devoid of organic matter. The action of sulphur is greater if it is previously mixed with the organic matter with which it is to act. The use of sulphur in the vineyard caused a very marked increase in the yield of grapes.

Sulphur ; Fertilising action of ——. V. V. Sabaschnikoff. Russ. J. f. exp. Landw., 1912, 821. Biedermann's Zentr., 1914, **43**, 282.

The soil used for the experiments contained 0·082% of sulphuric acid. Flowers of sulphur was applied in the proportion of 10 grms. per sq. metre. The increase in the weight of barley and rye on the sulphur plot over that on an untreated plot (2 sq. metres) was about 1·5 kilo. in each case.—J. H. J.

Plants ; Influence of manganese and aluminium on the growth of ——. T. Pfeiffer and E. Blanck. Landw. Versuchsstat., 1913, **83**, 257—281 ; Chem. Techn. Rep., 1914, **38**, 320.

Manganese salts, when added to soils, favour the growth of plants to a slight extent, but the cheaper manganese compounds are very sparingly soluble, so that large quantities have to be employed, and the actual benefit arising from their use is questionable. The addition of very small quantities of aluminium sulphate and manganese sulphate results in an insignificant stimulating action on the plants.—W. P. S.

Behaviour of ammonium phosphomolybdate with ammonium hydroxide. Sircar. *See* VII.

Patents.

Soil ; Sterilising of ——. P. J. Holmes, Norwich. Eng. Pat. 23,312, Oct. 15, 1913.

Steam is admitted to the space below a shallow cover placed a short distance above the soil, *e.g.*, a metal sheet provided with an outer jacket of insulating material, and with its edges bent downwards so as to rest on the soil.—W. P. S.

Seed grain ; Treatment of —— [with a solution of a manure and then with ultra-violet rays]. C. E. De Wolf, London, and H. E. Fry, Godmanstone, Dorset. Eng. Pat. 23,339, Oct. 15, 1913.

The grain is moistened with water, or a 15% sodium nitrate solution, and then submitted to the action of ultra-violet rays. Wheat, oats, and barley should be submitted to the rays for 5 hours ; maize and cottonseed for 7 hours. The process renders the grains more productive when sown.—W. P. S.

Fertilisers ; Plant ——. J. Keegan, Liverpool. Eng. Pat. 25,365, Nov. 6, 1913.

A fertiliser composed of two powders, solutions of which are applied separately and consecutively to the soil. One powder contains soluble ammonium and magnesium salts, to which potassium and aluminium salts may also be added, whilst the other consists of equivalent quantities of tribasic potassium or sodium phosphate and sodium silicate, or of dibasic potassium or sodium phosphate together with potassium and sodium carbonate.—W. P. S.

Fertiliser. T. L. Willson and M. M. Haff, Ottawa, Assignors to Southern Investment Co. of Canada Ltd., Montreal, Canada. U.S. Pat. 1,112,183, Sept. 29, 1914 ; date of appl., Aug. 17, 1912.

A dry fertiliser, consisting of calcium ammonium phosphate containing at least sufficient ammonia to correspond to the formula, $Ca(NH_4)H_3(PO_4)_2$.—O. R.

XVII.—SUGARS ; STARCHES ; GUMS.

Sugar in cane and beet ; Formation of ——. H. Pellet. Bull. Assoc. Chim. Sucr., 1913, **31,** 296, 322. Chem.-Techn. Rep., 1914, **38,** 3.

In the case of beet, intensive cultivation may lead to a daily formation of 1·20—1·25 grms. of organic matter (mostly sugar) ; in the case of cane (Egyptian) the average is only 0·8—0·9 grm. In a ripe cane weighing 1500 grms., the foliage contain 210 grms. of dry matter, of which 12 grms. are ash and 198 grms. organic, the cane itself containing 400 grms. of dry matter, of which 6 grms. are ash and 394 grms. organic.—O. R.

[*Sugar*] *Beet and cane ; Determination of the sucrose and reducing sugars in the foliage of the* ——. H. Pellet. Bull. Assoc. Chim. Sucr., 1914, **31,** 909—920.

Leaves and leaf-stalks are passed separately through a mincing-machine, and the finely divided material pressed two or three times, the pulp being removed and pounded in a mortar after each operation. *Sucrose by double polarisation*—500 c.c. of the filtered juice are treated with normal lead acetate (100 c.c. for the leaves, and 50 c.c. for the leaf-stalks), mixed, and filtered (giving solution A). 50 c.c. of the filtrate (solution A) are treated with 50 c.c. of sulphurous acid solution (sp. gr. 1·035—1·040), treated with 1 grm. of purified animal charcoal, mixed, and filtered, the clear liquid (solution B) being polarised in the 400 mm. tube, and the temperature noted. Another 50 c.c. of solution A are treated with 5 c.c. of hydrochloric acid (sp. gr. 1·19) and 25 c.c. of sulphurous acid solution (sp. gr. 1·035—1·040), and inversion effected according to Herzfeld's method, after which 1 grm. of purified animal charcoal is added, and the liquid filtered and polarised, the temperature again being noted (solution C). *Sucrose and reducing sugars by Fehling's solution.* 20 c.c. of solution B are rendered alkaline with sodium carbonate solution, 40 c.c. of Fehling's solution and sufficient water to bring the volume to 80 c.c. added, and the temperature raised to 65° C. for 10 minutes, the cuprous oxide precipitated being determined by the cyanide method (this J., 1914, 494). 50 c.c. of solution C are rendered alkaline with sodium carbonate solution, and the total reducing sugars determined as before. In calculating the sucrose by the double polarisation method, the factor 142·00 is used instead of 142·66 ; while the factor for converting the results obtained on the juice to those on the original substance is 0·91 for the leaves, and 0·97 for the leaf-stalks. According to the author, the results obtained by double polarisation should agree with those found by Fehling's solution to within 0·1%.—J. P. O.

Pectin substances in [*beet*] *sugar factory products* [*and their influence on the determination of raffinose*]. T. Koydl. Oesterr.-Ungar. Zeits. Zuckerind., 1914, **43,** 208—231. Chem.-Techn. Rep., 1914, **38,** 288.

Even when the difference between the values given by direct and double polarisation in the analysis of beet molasses amounts to as much as 3%, this " plus polarisation " is not due wholly to raffinose, of which there may be present only 1%, but is caused by the presence of pectin substances not precipitated by basic lead acetate, the amounts of which are shown to vary considerably throughout the campaign.—J. P. O.

Raffinose [*from cottonseed meal*] *; Preparation of* ——. C. S. Hudson and T. S. Harding. J. Amer. Chem. Soc., 1914, **36,** 2110—2114.

One kilo. of meal is treated with 5 litres of cold water, the mixture quickly filtered by suction, and the filtrate treated with a slight excess (about 200 c.c.) of basic lead acetate solution. The yellow lead precipitate is filtered off, excess of lead removed by hydrogen sulphide, and, after adding about 0·2 grm. of sodium hydrosulphite, the solution concentrated under reduced pressure to a syrup containing about 25% H_2O. Barium hydroxide (2 grms. of octahydrate for each grm. of raffinose) is added, the mixture warmed to not over 80° C., to effect solution, and gradually poured into 1·5 times its volume of commercial anhydrous methyl alcohol, and the granular precipitate ground to a fine powder, filtered off, and washed with methyl alcohol. The barium compound, suspended in about 1500 c.c. of water, is decomposed by gradual addition of 50% phosphoric acid solution until exactly neutral, the precipitate filtered off, and the last traces of barium removed by precipitating with sulphuric acid and again filtering. Fifty grms. of the vegetable carbon, " eponite," are added to the filtrate and filtered off after a few minutes, and the still yellow solution boiled *in vacuo* to a syrup containing 20—25% H_2O. Ethyl alcohol (95%, containing 0·3% HNO_3) is then added, just to saturation (as a rule 10—15 c.c.), and the mixture inoculated with crystals of raffinose hydrate and left overnight at 0° C. to crystallise, the separated crystals being ground with 75% alcohol, filtered off, and washed with alcohol. About 40 grms. of colourless raffinose crystals are obtained, and a further 10 grms. by treating the mother liquor again with barium hydroxide. The proportion of ash (0·5—1%) may be reduced by preparing a 50% aqueous solution, filtering, adding acidified alcohol as above, nearly to the point of cloudiness, and stirring. About 2·5% (referred to the original cottonseed meal) of pure raffinose hydrate, crystallising rapidly at the ordinary temperature, are thus obtained, and a further 0·5% by cooling the mother liquor to 0° C. After washing with 75% and then with 95% alcohol, the product contains less than 0·05% of ash and gives a specific rotation of 123·2° (anhydrous sugar) in 10% aqueous solution at 20° C.—F. Sodn.

Maltose and its oxidation products with alkaline hydrogen peroxide ; Structure of ——. W. L. Lewis and S. A. Buckborough. J. Amer. Chem. Soc., 1914, **36,** 2385—2397.

Maltose is oxidised by alkaline hydrogen peroxide largely without hydrolysis and without formation of saccharinic acids. A larger amount of oxygen is consumed than in oxidation with alkaline copper sulphate (this J., 1909, 1155) and larger amounts of formic and glycollic acids are formed. 100 grms. of anhydrous maltose gave 22·97 grms. of hydrolysed dextrose (24·97 grms. when corrected for decomposition of dextrose under similar conditions), 0·16 grm. of mannonic-lactone, 16·04 grms. of glycollic acid, 0·11 grm. of oxalic acid, 55·37 grms. of formic acid, and 4·44 grms. of carbon dioxide, together with 1·18 grms. of unidentified material, probably containing erythronic and *l*-threonic acids. The proportions and nature of the products are different from those obtained from dextrose (Spoehr, Amer. Chem. J., 1910, **43,** 238 ; Glattfield, Amer. Chem. J., 1913, **50,** 135) and the differences must be due to the glucosido-linkage between the two dextrose residues in the maltose molecule. Maltose is a γ-*d*-glucosido-*d*-glucose and the formation of relatively large quantities of glycollic acid indicates that the terminal (primary alcohol) carbon atom takes part in the glucosido-linkage, the formula hence being :

$$CH_2(OH).CH(OH).\overset{|}{C}H\,(\overset{O}{C}H.OH)_2.\overset{|}{C}H.O.CH_2(CH.OH)_4.CHO,H_2O.$$

Additional evidence in favour of this formula is cited and the mechanism of the oxidation is discussed. (See also Nef, this J., 1914, 366.)—A. S.

Formic acid ; Determination of —— in honey. H. Lührig and F. Doepmann. Jahresber. Chem. Untersuchungsamtes, Breslau, 1912—13, 24—26 ; Z. Unters. Nahr. Genussm., 1914, 27, 477—478.

When honey is mixed with water and submitted to steam-distillation, as in Fincke's method for the determination of formic acid (see this J., 1911, 82, 235 ; 1912, 402 ; 1913, 445), the first portion of the distillate, amounting to 1500 c.c., does not contain all the formic acid present. From 6 to 10 mgrms. of formic acid (or of volatile substances which reduce mercuric chloride) are obtained in each of the three successive quantities (500 c.c.) of distillate collected when the distillation is continued. When a mixture of 100 grms. of sugar, 300 c.c. of water and 1·5 grm. of tartaric acid is distilled with steam, the distillates contain a quantity of reducing substances equivalent to 10 mgrms. of formic acid. Tartaric acid and water alone yield a few mgrms. of reducing substances, and it is pointed out that it is quite possible that a part of these is derived from the rubber connections of the distillation apparatus. In the determination of formic acid in materials containing glyoxylic acid, the distillate should be treated with zinc and dilute sulphuric acid before the mercuric chloride reagent is added ; any basic zinc sulphate precipitated with the mercurous chloride is removed by treating the latter with dilute hydrochloric acid.—W. P. S.

Patent.

Manufacture of an absorbent or decolorising agent. Ger. Pat. 276,343. *See* IIb.

XVIII.—FERMENTATION INDUSTRIES.

Malt ; Purchase of —— on the basis of analysis. H. and J. M. Heron. J. Inst. Brew., 1914, 20, 465—487.

It is a common practice for the maltster to submit to the brewer samples of a run of malt at the beginning of a season, and contract to supply a definite quantity as required, each delivery to correspond approximately with the sample submitted. The suggestions for sampling made by the Committee of the Inst. of Brewing on Malt Analysis (see this J., 1906, 236) may be amplified as follows :—In sampling from sacks, there should be a minimum of five samples for all deliveries, and for large consignments one sample from every ten sacks. The samples should be drawn with a probe or spear and not with the hand, which may be moist. In the case of heaps, at least ten samples should be drawn (from different parts) from bulks up to 100 quarters, and 20—30 from larger bulks. All bins except tall silos, should be probed like heaps. In sampling from tall silos with a conical bottom ending in a spout, two or more sacks should be drawn and samples taken from them. The shaking of larger samples in tins, prior to taking smaller samples, is objectionable since the denser and less modified grains tend to accumulate at the bottom. The best method is to pour backwards and forwards six or more times from one vessel to another. Samples taken immediately after the malt has left the kiln tend to show a lower yield of extract, a higher diastatic activity and a darker colour, than those taken several days later, after the malt has cooled and been screened and brushed. Re-dried malt appears to continue to lose moisture after leaving the kiln, so sampling should be delayed for at least three days. Since the report of the Committee on Malt Analysis various possible sources of error in the determination of extract have been pointed out (see Jones, this J., 1908, 240 ; Day and Amos, this J., 1914, 434 ; Ling and McLaren, this J., 1908, 514 ; Baker and Hulton, this J., 1910, 644 ; Siau, this J., 1912, 197). A difference of ½—¾ lb. of extract between two determinations on the same sample is fair agreement and rather more latitude might be allowed in view of the imperfection of sampling. A consignment of malt, well loaded and dispatched and not unduly delayed in transit, will on an average absorb ½—¾ or even 1% of moisture, so that a maximum of 3% of moisture on delivery is not unreasonable. Siau and Hodson (J. Inst. Brew., 1909, **15**, 67) have pointed out possible sources of error in moisture determinations. In determining the diastatic activity of malt, the reaction of the starch solution is of great importance (see Jones, *loc. cit.*). An alkalinity equivalent to 1 c.c. of N/10 acid per litre, in the distilled water used, lowers the diastatic activity value about 4°. The tube method often gives results 2°—5° higher than the standard method. A difference of ± 5° between sale and delivery samples is reasonable. For colour determinations a difference of ± 1° is not excessive, for the determination is affected by the mode of illumination (see Baker and Hulton, this J., 1906, 552 ; 1907, 268) ; moreover the series "52" glasses do not match the nuance of all malts perfectly, and mild ale and high dried malts often tend to become paler on storage. Tables are given showing, for three different malts, a comparison of the various deliveries, with the sale and bulk samples.—J. H. L.

Yeast ; Some studies on ——. I. Relation of cell reproduction to the supply of free oxygen. II. Metabolism of the yeast cell, with special reference to the thermal phenomena of fermentation. H. T. Brown. Annals of Botany, 1914, 28, 197—226. J. Inst. Brew., 1914, 20, 541—544.

I. When yeast cells are seeded in a liquid containing dissolved oxygen and an excess of nutriment, and the available oxygen is limited to that initially present in the liquid, the total number of cells per unit volume tends to attain a maximum, which is independent of the number of cells seeded but, within certain limits of oxygen supply, is proportional to the initial amount of oxygen, and under these circumstances the rate of reproduction is not logarithmic but is a linear function of the time. The dissolved oxygen does not remain as such in the liquid during reproduction, but is rapidly absorbed by the seed-yeast before cell-budding commences. The author suggests that the "oxygen-charge" absorbed by each cell determines the reproductive power of the cell. If of two equal volumes of liquid, saturated with air, one contains more cells of seed-yeast than the other, and both are deprived of further access of oxygen, the dissolved oxygen will be rapidly absorbed by the cells ; those of the larger seeding will absorb a smaller "oxygen-charge" and therefore will possess a smaller reproductive power than those of the smaller seeding, but this disadvantage will be exactly counterbalanced by their greater number, so that the total number of new cells formed will be the same in both cases. The linear rate of reproduction is explained by the partition of the "oxygen-charge" amongst an increasing number of cells, whereby the rate of subdivision of the individual cells diminishes in inverse ratio as their total number increases. Pasteur first expressed the idea that the oxygen originally absorbed by the yeast from the surrounding medium is the *primum movens* which determines its subsequent power of reproduction. Although a yeast cell can, under favourable conditions, continue to take in oxygen from the medium if this is maintained saturated with air, the cell can only store up a limited amount of oxygen in a form available for subsequent reproduction. All attempts to increase this effective "oxygen-charge" by previously submitting the yeast to strong aeration, or even by passing pure oxygen through the liquid, were unsuccessful ; the yeast under these conditions continues to take up oxygen, but its potentiality of reproduction is not thereby increased. Under favourable conditions, with the yeast cells at a concentration of 1 in 1/4000 cub. mm of nutrient liquid, the volume of oxygen taken up by each cell and constituting the oxygen charge, is about 5 times the volume of the cell itself.

II. Experiments made with large volumes of fermenting wort indicated that the heat of fermentation (including heat of hydrolysis) of 1 grm. of maltose is about 125 calories. Between 14° and 16° C. a yeast cell ferments its own weight of sugar in 8½—9½ hours, and the heat generated in 1 hour, is sufficient to raise the temperature of the cell by 15° or 16° C. The temperature coefficient of fermentation by yeast is high. The following figures, calculated from data given by Slator, represent the relative rates of fermentation of top-fermentation brewery yeasts at temperatures starting from 5° C. and rising by increments of 5° to 40° C. :—1·00, 2·65, 5·59, 10·05, 15·80, 22·59, 30·50, 36·60. The apparently wasteful metabolism of the yeast cell is a necessity imposed by the conditions under which reproduction occurs in nature, *e.g.*, in fruit juices. These conditions are altogether different from those of the fermentation industries, where the fermentative faculty of the cells has been purposely enhanced and their reproductive faculties have been restricted.—J. H. L.

Yeast cells ; Staining of —— by Methylene Blue, etc. C. G. Matthews. J. Inst. Brew., 1914, **20**, 488—496.

The method of staining employed was to prepare an aqueous suspension of the yeast, sufficiently dense to show a just perceptible opalescence, and to treat portions of 3 c.c. with the staining solution, *e.g.*, 0·1 c.c. of a 0·1% solution of Methylene Blue, or 0·2 c.c. $N/10$ solution of iodine diluted twenty-fold. A number of pitching yeasts were investigated in this way. With Methylene Blue, dead and torpid cells assumed a pallid stain, but from 1 to 20% of the cells stained a sapphire colour. The following conclusions are drawn respecting this deeper staining :—It is not confined to *S. Cerevisiae* though shown best by this race. It is independent of the glycogen reaction of the cells, and, in large measure, of staining by other dyes, as Indigo Carmine or Cochineal Carmine. The cells so stained are not necessarily dead or torpid in the ordinary sense. Those likely to stain can be identified by their higher refractive power, showing up brightly when the microscope objective is slightly out of focus, and they usually have smaller or ill-defined vacuoles or none at all. The progeny of a non-staining cell may stain, even to 3 to 4 individuals, though staining cells seldom give rise to non-staining ones. The budding of a staining cell seems frequently to be arrested when a small bud has formed, but sometimes a pair of equal-sized cells, presumably mother and daughter, will stain, and such cells tend to remain attached. In stained cells all parts take the stain. The phenomenon appears to indicate a change of state and possibly of function in the cell, probably a resting stage in which there may be accumulation of reserve nutriment (but not necessarily glycogen, though it may be fat) and a perceptible diminution or temporary arrest of the vegetative activity. It is not necessarily a permanent change, as a fresh fermentation under favourable conditions may entirely alter the condition of the cell.—J. H. L.

Yeasts ; Assimilation of maltose by ——. G. Kita. J. Chem. Ind. Tokyo, 1914, **17**, 274—278. Chem.-Techn. Rep., 1914, **38**, 262.

In solutions containing ammonium nitrate as source of nitrogen, Schuchardt's "pure maltose" was less readily assimilated by yeasts after it had undergone a preliminary extraction with absolute alcohol. The commercial maltose appears therefore to contain besides protein (see Kluyver, this J., 1913, 803 ; Davis, this J., 1914, 1068) some other constituent, similar to oryzanin which increases its assimilability.—J. H. L.

Enzymes of yeast ; Susceptibility of the various —— to thermo-regeneration. G. Bertrand and M. Rosenblatt. Comptes rend., 1914, **158**, 1823—1826.

Unlike the sucrase, neither the maltase nor the catalase of yeast maceration juice exhibited the phenomenon of thermo-regeneration (see this J., 1914, 658). The activity
of both was completely destroyed by heating the ju
to 70° C. for 1 min., and was not restored even partially
higher temperatures.—J. H. L.

Beers ; Chilled bottle ——. A. Hadley. J. Inst. Bre
1914, **20**, 504—533.

There are two main methods of chilling beers, *viz.*, c
storage and quick chilling, and the latter, which is l
costly, provided always that the beer is properly c
ditioned, gives results equal to the slow chilling proce
The beer is run or pumped from the skimming vessels
glass-lined copper or wooden tanks to condition. H
it is dry-hopped if necessary, primed if customary, a
usually partially fined. A conditioning is thus effect
which cannot be attained in casks, whilst there is far l
waste, and the beer is cleaner and brighter after havi
settled for a few days, so that the filters run far long
than when the beer is conditioned in casks. In or
to save time, many brewers have installed a quick-chil
of the counter-current or some similar type betwe
the conditioning and chilling vessels. The beer can th
be cooled to 35° F. (2° C.) before entering the chilli
and carbonating vessels in which its temperature is s
further reduced, *e.g.*, to 28° F. (—2° C.). Continuo
carbonation appears to be working satisfactorily in
number of breweries. The chilling is kept entir
separate from the carbonating, and the chilled beer
pumped through the carbonator which is placed eit
between the chilling plant and the filter or between t
chiller and the filling machines. This arrangement
said to give more uniform results, keeping the beer
quieter condition for bottling. The author gives a num
of practical notes on filters, refrigerating plant, bottli
machines, washing plant and stoppering and labelli
The collection of carbon dioxide from fermentation v
permits of considerable economy. Owing to the dang
of overheating the gas, and thus affecting the flavo
of the carbonated beers, it is not advisable to compr
the carbon dioxide to more than about 100 lb. per sq.
The collection of the gas should be started about 15 ho
after pitching, and is usually continued for 24—30 hou
The average amount produced from a 100-barrel ferment
tion vat is roughly 10 lb. per hour, and the total quant
should be sufficient to carbonate about 400 barrels
beer, or a smaller number if carbon dioxide is used
top-pressure.—J. H. L.

"Mirin" and its turbidity ; Chemistry of ——.
Takahashi, Y. Shimazu and S. Hagiwara. J. Agr
Tokyo, 1913, **5**, 179—187. Z. Unters. Nahr. Genuss
1914, **27**, 604—605.

"*Mirin*" is a rather thick, yellowish brown, strong
alcoholic beverage made from swollen rice, ferment
by cultures of *koji* or *shoyu*. After fermentation h
proceeded for 40—50 days in open vessels, the express
liquid is allowed to stand until clear. With a sp. gr.
about 1·138, it contains 10—12·54% of alcoh
1·86—4·96% of dextrin, 30·1—32·89% of sugar and abo
0·12% of ash. Fermentation is accompanied
saccharification of starch and decomposition of protei
Organic acids are also formed, but if in too large amoun
they promote excessive proteolytic enzyme action and t
amino-acids produced give rise to turbidity in the bevera
To avoid this the acidity of the mash must be kept with
certain limits by addition of sodium carbonate, and ca
should be exercised in the selection of the yeast materi

Wine ; Colour reactions of constituents of ——.
Schaffer. Mitt. Lebensm.-Unters. u. Hyg. Schwe
Gesundheitsamt, 1913, **4**, 206—211. Z. Unters. Na
Genussm., 1914, **28**, 120—121.

White wines and raisin wines are almost free fro
tryptophol (β-indole-ethylalcohol), whereas red win
invariably contain it. It may be isolated by shaki
10 c.c. of the wine with a mixture of ether, amyl alcoh
and petroleum spirit (8 : 1 : 3) and treating the resid
left on evaporating the extract with a few crystals

dimethylaminobenzaldehyde, a little alcohol, and a few drops of 25% hydrochloric acid. In the presence of tryptophol (1 : 10,000) a violet coloration is obtained slowly at the ordinary temperature and immediately on heating. In addition to *l*-arabinose, wines may contain another pentose, which yields furfural when the wine is distilled, even without the addition of hydrochloric acid. For the furfural test 10 c.c. of the wine (diluted if necessary) are distilled with 10 c.c. of hydrochloric acid (sp. gr. 1·18), until about 16 c.c. of distillate have been obtained. About 10 c.c. of this are mixed with 6 to 8 c.c. of 85 to 98% alcohol and 1 to 2 c.c. of a cold saturated solution of phloroglucinol in hydrochloric acid (sp. gr. 1·06). Any violet coloration will usually appear in about 4 to 5 hours (sometimes 8 to 9 hours), and generally disappears again in a few hours. Wines containing more than 4 grms. of sugar per litre should be diluted and fermented before testing. Artificial wines (raisin wine and wine from spent grapes) usually give a negative or faintly positive result, whilst natural wines invariably give a distinct reaction. A mixture of wine from spent grapes with 20% of red wine gave the reaction. The violet coloration was faintest with light Spanish wines and French and Spanish red wines.—C. A. M.

Quercetin in wine; Determination of ——. T. v. Fellenberg. Mitt. Lebensm.-Unters. u. Hyg. Schweiz. Gesundheitsamt, 1913, **4**, 1—14. Z. Unters. Nahr. Genussm., 1914, **28**, 118—119.

The colouring matter quercetin can be readily extracted from wine by ether; it is nearly insoluble in water but is soluble in strong alcohol. Wines also contain a water-soluble tannin, probably quercitrin, as the main constituent of their colouring matter. The colouring matter extracted with ether dyes wool mordanted with alumina yellow, and that mordanted with alumina and tin bright yellow in dilute and orange yellow in concentrated solutions. Unmordanted animal and vegetable fibres are not dyed. To determine the yellow colouring matter 10 c.c. of the wine are extracted with cold ether, the ethereal extract distilled, and the residue dissolved in water, and (in the case of red wines) heated for 10 mins. on the water-bath with unmordanted woollen threads 10 cm. in length to remove the foreign dirty-grey colouring matter. The quercetin is then absorbed by 0·01 grm. of mordanted wool (10 mins. in the water-bath), and the dyed fibres washed, dried, and compared with standard fibres dyed with a solution of quercetin (1 mgrm. per litre). White wines seldom contain more than 0·1 mgrm. whilst red wines contain up to 48 mgrms. of quercetin per litre. The yellow colouring matter in the wine is derived from the grape skins, and should a white wine contain about 8 mgrms. thereof it is derived from the spent grapes (*Tresterwein*); wines containing more than 4 mgrms. are suspicious. The colouring matter is first formed during fermentation in contact with the skins. Tea leaves contain a colouring matter resembling but not identical with quercitrin. The yellow colouring matter in wine consists of quercitrin, traces of quercetin, and a decomposition product of chlorophyll.—C. A. M.

Saffron yellow in white wine; Detection of ——. V. Kreps. Arch. Chem. u. Mikrosk., 1912, **5**, 24—31. Z. Unters. Nahr. Genussm., 1914, **28**, 121.

The colouring of white wines with saffron is legal in Hungary though forbidden in Austria. "Saffron yellow" differs from the natural wine colouring matter in not being affected by alkalis. It does not react with strong solutions of organic acids or with strong mineral acids. It is precipitated by lead acetate as a lemon yellow precipitate, whilst the filtrate shows a light yello coloration. It can be largely extracted with amyl alcohol from the wine acidified with hydrochloric or sulphuric acid, but not from an alkaline solution. Fat-free wool will fix the saffron colouring matter, but it can be extracted again practically unchanged by means of 3% ammonia solution. —C. A. M.

Potassium and magnesium; Determination of —— *by physico-chemical volumetric methods. Application to the analysis of wines.* M. Duboux. Comptes rend., 1914, **159**, 320—323. J. Chem. Soc., 1914, **106**, ii., 745—746. (Compare Dutoit and Duboux, this J., 1908, 871, 912.)

Potassium can be estimated in wines by determining the conductivity of the solution after the repeated additions of small amounts of chloro-platinic acid, after the addition of eighteen times its volume of alcohol. A change in the direction of the conductivity curve indicates the end of the precipitation. It is necessary to wait some time for the conductivity to become constant after each addition of the reagent, and also to destroy the organic matter in the wine by evaporation and ignition prior to the estimation. For the estimation of magnesium, the conductivity is measured in a solution containing 0·02% NH_3 and 0·06% NH_4Cl after the addition of measured small quantities of $N/2$-phosphoric acid. Before performing the titration, the organic acids in the wine must be destroyed and the phosphoric acid and lime removed by precipitation. Fifty c.c. of the wine are treated with 3 c.c. of $N/1$-sulphuric acid and 100 c.c. of alcohol. After two hours the calcium sulphate is filtered off, and to the filtrate is added 3·5 c.c. of $N/1$-ammonia and 7 c.c. of a 16% solution of lead nitrate, which precipitates the phosphates. The whole is warmed on the water-bath, filtered, and to the filtrate 5 c.c. of $N/1$-sulphuric acid are added and the lead sulphate filtered off. The solution is evaporated to dryness and calcined, the residue is dissolved in 5 c.c. of $N/10$-HCl, 50 c.c. of $N/10$-ammonia are added, and the liquid titrated with the phosphoric acid.

Products derived from the date palm. Raynaud. *See* XIXa.

Methyl alcohol in corn silage; Occurrence of ——. Hart and Lamb. *See* XIXa.

Patent.

Liquids such as stout, beer and the like; Pasteurising, sterilising and cooling ——. H. S. Gregory, Palmers Green, Middlesex. Eng. Pat. 19,159 of 1913; date of appl., Feb. 23, 1914.

The liquid is pumped under pressure into the upper part of a jacketed conical chamber over the sides of which it is distributed in the form of a film; the supply of heating agent to the jacket and the flow of liquid to the chamber are controlled by a thermostatic device. The sterilised liquid flows through a float-chamber into a cooling chamber, the flow being so regulated by the float that the liquid remains in the float-chamber for from 15 to 20 minutes. The cooled liquid escapes through a pipe into which is also passed the liquid resulting from the condensation of the vapours from the heating vessel. —W. P. S.

XIXa.—FOODS.

Milk samples for analysis; Preservation of ——. J. Tillmans, A. Splittgerber and H. Riffart. Z. Unters. Nahr. Genussm., 1914, **27**, 893—901.

Thymol, phenol, creosote, and sodium fluoride exert only feeble preservative action, the milk coagulating after 24—48 hours. The coloration produced by potassium bichromate interferes with the determination of acidity. Chloroform raises considerably the refractometric value and the (apparent) fat-content, and creosote lowers the specific gravity of the milk. The diphenylamine test for nitrates is rendered worthless by the presence of potassium bichromate, and less sensitive by thymol, creosote, mustard oil and phenol. Mercuric chloride is the only satisfactory preservative. At a concentration of 0·03—0·04% it keeps the milk fresh for 120 hours, with no appreciable increase of acidity; it has no influence on the determination of specific gravity, refractometric value and fat-content, and is the only one of the substances studied which preserves any nitrates in the milk from decomposition so that they can be accurately determined by the diphenylamine method (Tillmans, this J., 1911, 44) even after 120 hours. It is used by the Municipal Hygienic Institute of Frankfort-on-Maine in the official milk control, the samples being treated with 2 c.c. of a 0·5% solution per 250 c.c. Its toxic nature demands certain precautions, *e.g.*, the samples are treated with 0·2 c.c. of a 1% aqueous solution of Congo-red; this colouring matter has no influence on the analytical results, and in the coagulation of proteins by calcium chloride it is completely precipitated, leaving a colourless serum. (Cp. Rocques, this J., 1912, 742; Denigès, this J., 1913, 670.)—J. H. L.

Milk; Titration of —— with alcohol of various strengths. F. Löhnis. Molkerei-Zeit., Hildesheim, 1914, 153. Biedermann's Zentr., 1914, **43**, 496—497.

Two c.c. of milk are run into a beaker so as to form a thin layer over the bottom and titrated with alcohol until the first appearance of coagulation. The number of c.c. used is called the "alcohol number" of the milk. If more than 6 c.c. are required, the end point is uncertain. Alcohol of 70, 80 and 90% strength by volume was used, and it was found that 80% alcohol gave the most reliable results. The alcohol number gives an indication of the number of bacteria in the milk; with a low germ content the milk requires more than 4 c.c., with a medium germ content 2—4 c.c., and with a high germ content less than 2 c.c. The alcohol number indicates also the quality of the milk.—J. H. J.

Margarine; The butter-fat content of ——. W. Arnold. Z. Unters. Nahr. Genussm., 1914, **27**, 379—388.

The following determinations should be made in order to determine the presence or absence of butter-fat in margarine :—saponification value, Reichert-Meissl value, and Polenske value, both of the fat itself and of that portion which is soluble in alcohol; the molecular weight of the water-soluble fatty acids should also be determined. In the case of a margarine free from butter-fat and palm fats the Reichert-Meissl and Polenske values will be not greater than 0·55. The relation between the Reichert-Meisal and Polenske values will be as follows when the margarine consists of animal fats (or vegetabl fats free from volatile fatty acids) and coconut oil :—

Coconut oil %	2	6	10	14	20	25	30	40	5
Reichert-Meissl value	0·9	1·65	2·37	3·2	3·9	4·5	4·84	5·8	6·7
Polenske value	0·05	0·95	1·3	1·65	2·4	3·0	3·65	5·05	6·5

When the Reichert-Meissl value is greater than tha indicated in the table, the presence of butter-fat i indicated; when it is lower, palm-kernel oil is present The presence of palm-kernel oil is also indicated by Polenske value exceeding 0·6, when the molecular weigh of the soluble fatty acids is above 130, and by the characte of the volatile insoluble fatty acids; the latter, bot from the original fat and from the alcohol-soluble fat are solid. In the case of margarine containing butter-fa and free from palm oils, the Reichert-Meissl and Polensk values of the fat and its alcohol-soluble portion will giv the proportion of butter-fat present; the molecula weight of the soluble fatty acids will lie between 97 an 107.—W. P. S.

Butter; Water-content of ——. W. Theopold. Be Nahrungsm. Untersuchungsamtes Bromberg, 1913, 1 Z. Unters. Nahr. Genussm., 1914, **28**, 109—110.

It has been asserted that butter increases in weigh by absorption of water when moistened externally o placed in cold water for 70 hours. This is disproved b experiments cited. A sample of butter containing 22·9 water showed 22·6% after the treatment, whilst anothe sample with 18·8% showed 18·2%.—C. A. M.

Wheat and its products; Composition of ——. H. Kalnin and A. Schleimer. Z. ges. Getreidew., 1913, **5**, 199 Chem.-Techn. Rep., 1914, **38**, 174.

Wheat was separated by milling into various portion the composition of which is shown in the following table :-

	Flour.			Feeding meal. 78·71 to 80·92 %	Fine bran. 80·92 to 89·34 %	Coarse bran. 89·34 to 92·72 %	Husk-bran. 92·72 to 98·47 %	Husk offal 1. 98·47 to 99·78 %	Husk offal, 2. 99·78 to 99·79 %	Germ. 99·79 to 100 %
	0 to 31·48 %	31·48 to 73·46 %	73·46 to 78·71 %

—W. P. S.

Feeding-stuffs; Valuation of —— by means of chemical analysis. A. Smetham. J. Roy. Lancashire Agric. Soc., 1914. Analyst, 1914, 39, 481—491.

The results of analyses of a large number of feeding-stuffs are shown in the following table (*cf.* this J., 1910, 39, 40. "Albuminoids" represent total nitrogen, multiplied by 6·25. "Digestible carbohydrates" include all non-nitrogenous organic matter, except woody fibre and fat. The "food units" are calculated on the assumption that oil and albuminoids are of equal value, and together are 2·5 times as valuable as carbohydrates. When a food has been ascertained to have poisonous properties, the fact is stated in the tables, but the absence of such a statement does not necessarily imply that the foods are wholesome:

Name.	Water.	Oil.	Albuminoids.	Digestible carbohydrates.	Woody fibre.	Mineral matters.	Sand and silica.	"Food units."

* During the past few years an alteration has taken place in the character of decorticated cottonseed cake and meal from the United States. At present, very little cottonseed is being imported into the United Kingdom as cake, the bulk of that arriving here being ground into meal before shipment. More woody fibre is present than formerly. The contracts on which American decorticated cottonseed meals are now usually sold require choice meal to contain at least 40, prime meal at least 38, and good meal at least 35·5% albuminoids, with allowances if the outturn is below the stipulated amount. Texas meal is usually sold on a basis of 52% oil and albuminoids together.

ye flour; Detection of small amounts of —— in wheat flour. R. Fanto. Z. Unters. Nahr. Genussm., 1914, **28,** 79—83.

en grms. of the flour are mechanically shaken for 2½ hours ith 100 c.c. of water, the mixture centrifuged for 1 hour, nd the efflux velocity at 17° C. of the aqueous extract etermined in Traube's "stalagmometer" (Biochem. eits., 1910, **24,** 341). Extracts of different kinds and rades of wheat flour gave results ranging from 57 to 72 ses. (water 51 secs.), the lower values being given by and-sifted samples, while commercial grades did not fall elow 62. In the case of rye flours of various kinds the alues ranged from 178 to 709 secs. Mixtures of wheat our with 2½% of rye flour of similar colour showed efflux elocities of 98·5 to 112 secs. The constituent to which ye flour owes its viscosity is not a protein, but appears o be the "gum" isolated in impure condition by Ritt-ausen (J. prakt. Chem., 1867, 321) by extracting the our with dilute alcohol and adding strong alcohol to he extract. This substance forms a colloidal suspension n water.—C. A. M.

lour and bread; Determination of fat in ——. M. P. Neumann, H. Kalning and G. Grujic. Z. ges. Getreidewesen, 1912, **4,** 220—226; Z. Unters. Nahr. Genussm., 1914, **27,** 748—749.

he fat present in flour may be extracted completely ith ether, but it is advisable to dry the flour previously or 3 hours at 100° C. The flour may also be dried at 80° C. for a short time (about 30 mins.) without nfluencing the yield of fat, but low results are obtained hen the flour is maintained at 120° C. for 17 hours. at cannot be extracted directly from dried and powered bread; the starch must first be hydrolysed. Five rms. of bread crumbs are placed in a flask, 50 c.c. of ater and 2 c.c. of hydrochloric acid are added and the ixture is heated for 90 mins. in a boiling water-bath nder a reflux condenser. After cooling, the mixture neutralised with sodium hydroxide solution, then cidified with 1 drop of hydrochloric acid, and filtered. he insoluble portion is washed with hot water, dried for hours at 105° C. and extracted with ether in a Soxhlet pparatus.—W. P. S.

ilage formation; Chemical changes during ——. R. E. Neidig. J. Amer. Chem. Soc., 1914, **36,** 2401—2413. (See also this J., 1913, 156.)

he formation of silage takes place within 3 weeks at the most from the filling of the silos and observations on hree types of silo (wooden, hollow tile, and concrete) howed that there is no essential difference in the quality f the silage produced, provided that the corn used is n the proper stage of maturity, that the proper amount f water is added, that the silos are carefully filled, and hat the walls are smooth and air-tight. The maximum emperature attained in the silos was 91° F. (33° C.). arbon dioxide developed very rapidly after filling the ilo and free oxygen disappeared entirely after the second r third day. Non-reducing sugars were rapidly converted into reducing sugars and the latter then decreased n amount but did not entirely disappear. The amounts f volatile acids and of racemic lactic acid increased daily. Small amounts of alcohol were formed.—A. S.

Methyl alcohol in corn silage; Occurrence of ——. E. B. Hart and A. R. Lamb. J. Amer. Chem. Soc., 1914, **36,** 2114—2118.

Normal corn silage is shown to contain a small proportion of methyl alcohol, part at least of which is probably formed by the action of micro-organisms on glycine. —F. Sodn.

Date palm; Products derived from the ——. F. Raynand. J. Pharm. Chim., 1914, **9,** 391—396, 454—458.

Almost every part of the date palm is made use of. The fruit is largely consumed by the Arabs and exported and is also made into a preserve called "Roub." Inferior and damaged dates are fermented and distilled, yielding an alcoholic spirit. The stones after softening in water are used as cattle food. The terminal bud or palm cabbage is eaten and the trunk gives a valued timber. A copious flow of sap is obtained by making incisions in the stem and this is either consumed immediately as a beverage or fermented to give the beverage called "Lagmi." Lagmi is a milky liquid with an insipid taste. The composition varies with the length of time it has been fermented, the alcohol content gradually increasing up to about 5%. Lagmi contains starch grains and yeasts in suspension. The former are both round and oval with distinct rings and hilum. On adding baker's yeast to Lagmi a further energetic fermentation takes place, giving another palm wine "Kiacham," a clear liquid with an acid taste containing 7 to 8% of alcohol. A sample of the spirit obtained by distilling the fermented dates had sp. gr. 0·940 and contained 48% of alcohol. *Roub* prepared by boiling dates for a long time with water is a reddish-brown syrupy liquid with a sweet then astringent taste. An average sample contained: dextrose 50, sucrose 20, pectins 3, tannin 4, mineral matter 2%. The variety of date known as "Ghars" yields a sugary juice which after boiling forms a date syrup or date honey called "Assal."—T. C.

Cassava roots and refuse. M. Kling. Landw. Versuchstat., 1913, **82,** 211—235; Chem.-Techn. Rep., 1914, **38,** 47.

Dry cassava roots or manioc contain: crude protein. 1·40; crude fat, 0·38; non-nitrogenous extractive matters 94·13; crude fibre, 2·12 and ash 1·96%; they are therefore exceptionally poor in protein and fat. The extractive matters consist mainly of starch: sucrose was found to the extent of 0·5%. The refuse from the manufacture is worked up as fodder meal, which possesses similar characters: it is analogous in nature to pressed potatoes. This meal is available for all kinds of stock and especially suitable for calves: it should preferably be mixed with some other fodder richer in protein.—I. F. B.

Salicylic acid; Determination of —— in jams. H. Serger. Z. Unters. Nahr. Genussm., 1914, **27,** 319—322.

Twenty grms. of the jam are heated nearly to boiling with 30 grms. of water, filtered while hot, and 25 grms. of the cooled filtrate shaken with 5 c.c. of dilute sulphuric acid (1 : 3) and 100 c.c. of a mixture of 300 c.c. of petroleum spirit and 200 c.c. of chloroform. Fifty c.c. of the petroleum spirit-chloroform layer are treated with 1 c.c. of dilute ferric chloride solution, then diluted with water to 100 c.c., and shaken for 1 minute. The petroleum spirit-chloroform layer is drawn off, the aqueous portion is diluted to 100 c.c., and the coloration compared with that given by a definite quantity of salicylic acid. For the purpose of comparison, the colorations should not exceed in intensity that of a N/500 potassium permanganate solution; if stronger, the solution must be diluted accordingly. A method described by Heintz and Limprich (this J., 1913, 763) was found to be untrustworthy for the detection of very small quantities of salicylic acid, but the test may be improved by using a larger volume of petroleum spirit, say 30 c.c., for the extraction.—W. P. S.

PATENTS.

Baking preparation. R. A. Holbrook. Assignor to Victor Chemical Works, Chicago, Ill. U.S. Pat. 1,113,632, Oct. 13, 1914; date of appl., Dec. 15, 1913.

A baking powder consisting of a suitable carbonate, monocalcium phosphate, and disodium phosphate.—W.P.S.

Sterilising fluids containing fat globules; Method and apparatus for ——. N. J. Nielsen, Aarhus, Denmark. Eng. Pat. 20,274, Sept. 8, 1913.

See Fr. Pat. 467,373 of 1914; this J., 1914, 882.—T. F. B.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Auto-purification of ——. Flamand. Bull. Soc. Chim. Belg., 1914, **28**, 9—10.

Blondiau's draining bricks may be used as a support for the material in a sand filter and extract the water from the sand by capillarity. They are made of a number of folds of earthenware so moulded that each brick consists of 16 draining tubes in parallel, of which half have their opening towards the sand and the other half have their opening towards the well. The tubes are flattened so that their filtering surface may be a minimum. Under a charge of 4 or 5 metres of sand and water, the delivery of each brick is about 100 litres per day. The water leaves the brick slowly, so that only an abundant oozing is seen. Sewage passed through a filter of this kind had all its organic matter oxidised and mineralised.—J. H. J.

Drinking water; Sterilisation of small quantities of ——. H. Langer. Deutsch. Med. Wochenschr., 1913, **39**, 1837. Chem.-Techn. Rep., 1914, **38**, 146.

Pathogenic bacteria can be destroyed even in highly contaminated potable waters, without adversely affecting the taste of the water, by adding 0·5 grm. of bleaching powder (equal to 0·12 grm. of free chlorine) mixed with an equal weight of sodium chloride to each litre of water and subsequently adding the calculated quantity of sodium percarbonate and filtering. (See also Ger. Pat. 260,653; this J., 1913, 840.)—T. C.

Disinfection of drinking water with chlorine; Influence of organic substances on the ——. E. Haïri. Z. Hyg., 1913, **75**, 40. Chem.-Techn. Rep., 1914, **38**, 10.

The chlorine absorption power is best determined by treating the water with an excess of bleaching powder, allowing to stand for one hour, and titrating the excess of chlorine in weakly acid solution.—O. R.

Water; Detection and significance of B. coli in ——. W. Plücker. Z. Unters. Nahr. Genussm, 1914, **27**, 521—543.

A synopsis is given of the large amount of work and investigation which has been carried out regarding this subject and a complete bibliographical list is appended to the paper. *B. coli* consists of short rods, is capable of liquefying gelatin, does not form spores, ferments lactose, and responds more or less completely to certain tests, among which are the Neutral Red and indole reactions; about 50 different types of the bacterium have been described. It occurs in the intestines of all warm-blooded animals, but its presence in cold-blooded animals is open to doubt. The bacterium is also widely distributed in soils, etc., and appears to be capable of surviving therein for a longer period than in water; it lives longer in pure than in dirty water, and in sterile water may survive for more than 50 days. The various tests which have been proposed for the detection of *B. coli* in drinking water are referred to, and the conflicting opinions regarding the significance of the presence of the organism in a water supply are discussed. Much depends on the locality and surroundings of a spring or well as to the relative number of organisms which may be tolerated. Neither the number of colonies per c.c. nor the coli test give definite indication as to the risk of infection unless the geological formation, properties of the soil, manuring, etc., of the neighbourhood from which the water is obtained be taken into account.—W. P. S.

Potassium; The perchloric method of determining ——, *as applied to water analysis*. C. Scholl. J. Amer. Chem. Soc., 1914, **36**, 2085—2089.

An aliquot portion of the water is evaporated to 150 c.c., acidified with 10 c.c. of concentrated hydrochloric acid, precipitated with 10% barium chloride, added drop by drop to the boiling solution, boiled for 15 minutes, filtered, and evaporated to dryness; ammonium salts are expelled by heating, the residue dissolved in 20 c.c. of hot water, 20% perchloric acid solution added, slightly in excess of that required to combine with the bases present, the mixture evaporated to dryness, 10 c.c. of hot water and a little perchloric acid added, the mixture again evaporated, and the evaporation, after treating with water and perchloric acid, repeated until white fumes appear; the perchlorate residue is then exhausted with 25 c.c. of 96—97% alcohol, containing 0·2% of perchloric acid, filtered through a Gooch crucible, washed with the perchloric acid-alcohol mixture, and dried at 120°—130° C. The asbestos packing of the crucible is washed with the solution of perchloric acid in alcohol before using, and is preferably employed repeatedly without disturbing, the perchlorate being removed with hot water. If both sodium and potassium are to be determined, the precipitation with barium chloride is omitted.—F. Sodn.

Nitrites in water; Detection of ——. Bornand. Mitt. Schweiz. Ges.-Amt, 1913, **4**, 285. Chem.-Techn. Rep., 1914, **38**, 146.

Rochaix's Neutral Red reagent is unsuitable for the detection of nitrites in drinking water, as is also Denigès' strychnine sulphate reagent (see this J., 1914, 1070) owing to the case with which it decomposes. The Ilosvay-Lunge reagent (sulphanilic acid) is more suitable for this purpose than those of Barbet and Jandrier (resorcinol sulphuric acid) and Mnoucha Chwilewizky (indole).—T. C

Silica in natural waters, alkaline softened boiler feed waters, and concentrated boiler waters. A. Goldberg. Z. Unters. Nahr. Genussm., 1914, **27**, 265—273.

Twenty-two samples of waters of all kinds contained soluble silica, which was reduced by about 50% on filtration through wood wool, apparently through adsorption of the colloidal silica. After treatment with alkali (caustic soda and sodium carbonate, alkali with aluminium sulphate, the mixed lime process) soft waters relatively rich in silica deposited scarcely any silica, whilst hard waters lost only a fraction of their dissolved silica when boiled. When heated in a boiler under pressure, however, neutral or slightly alkaline softened waters lost practically the whole of their dissolved silica, usually as silicate. The deposit thus formed may cause local overheating and pitting of boilers. The dissolved silica probably also contributes to the acidification of water heated in boilers under pressure. For example, when solutions of 5 grms. of $MgCl_2$, $Mg(NO_3)_2$, KNO_3 and NaCl in 50 c.c. of water, were distilled with 1000 c.c. of an approximately 0·1% solution of colloidal silica, the residue (50 c.c.) showed an acidity (up to $N/10$), whilst the distillates were all acid, especially in the case of $MgCl_2$ and $Mg(NO_3)_2$. The colloidal silica solution was neutral to Methyl Orange, Congo Red, and metanitrophenol, and when distilled alone yielded a neutral distillate. (See also page 1079.)—C. A. M.

Benzine; Accidents caused by —— *in* 1913. Chem. Fabrik Griesheim-Elektron. Chem.-Techn. Rep., 1914, **38**, 89.

During 1913 there were 148 accidents in Germany caused by benzine, resulting in 132 cases of serious injury and 71 deaths. Compared with 1912 the cases of injury showed a decrease of 23·7% and the deaths an increase of 24·5%. The accidents were distributed as follows:—Chemical cleaning works, 6; druggists' stores, etc., 8; in transport, etc., 54; motor driving, 50; illumination, 4; and in the hands of the public, 23. Two workmen were killed by the narcotic action of the vapours.—C. A. M.

Boiler enamel; Dangerous ——. Ber. Sächsisch-Thüring. Dampfkessel-Revisionsvereins zu Halle a. S. Minist. d. Hand. u. Gew. Verw., 1914, 21. Chem.-Techn. Rep., 1914, **38**, 89.

The boiler enamel, "*Siderosthen*," which had caused several workmen to faint in a boiler, had a flash-point of 19·5° C. It was a coal-tar or oil-gas tar product containing considerable quantities of volatile toxic light oil.
—C. A. M.

Eosin; Action of —— on bacteria, ferments, and mould fungi. H. Zeiss. Arch. Hyg., 1913, **79**, 141. Chem.-Techn. Rep., 1914, **38**, 3.

In most cases the addition of as much as 10% of eosin to the cultures was harmless, but in the case of aerobic spore carriers as little as 0·5% stunted their growth without affecting their powers of resistance.—O. R.

Petroleum and its derivatives; The antiseptic properties of ——. K. Charitschkow. Bergingenieur-Ges., 1913, **4**, 14. Chem.-Techn. Rep., 1914, **38**, 391. (See this J., 1914, 763.)

The zinc and copper salts of the naphthenic acids, dissolved in petroleum, have been applied in Russia for the impregnation of timber. An ammoniacal solution of the copper salts of these acids, together with other ingredients, constitute the so-called "Kupriol," a substitute for "Carbolineum."—J. N. P.

Carbon monoxide in mine air; methods of determination. Harger. *See* IIA.

Patents.

Water; Apparatus for softening and purifying ——. G. R. Shankland, Manchester. Eng. Pat. 25,728, Nov. 11, 1913.

Tubes packed with zeolites are arranged vertically in a casing, the upper and lower ends of the tubes entering small chambers at the top and bottom of the casing, respectively. The water to be treated is passed downwards or upwards through these tubes. The spaces between the tubes may also be packed with zeolites and used separately or in conjunction with the tubes. A tank containing revivifying solution is situated above the apparatus and means are provided for cutting out any portion of the apparatus for the purpose of revivifying the zeolites contained therein.—W. P. S.

Nitrogenous waste, sewage sludge and the like; Apparatus for the treatment [*destructive distillation*] *of* ——. W. D. Menzies, Westcliff-on-Sea, Essex, J. Menzies, London, and "S.O.S.," Ltd., London. Eng. Pat. 21,656, Sept. 25, 1913.

The material is delivered into a hopper fitted with heated rollers and thence on to endless travelling conveyors situated one above the other in heating and drying chambers. On leaving the drying chambers the material is delivered by a centrifugal or other charging machine into horizontal retorts where it is heated to 700°—900° F. (371°—482° C.) by means of steam or hot air introduced through perforated pipes. The material is then conducted into inclined retorts where it is distilled, these retorts being heated by a furnace. The oils, ammonia, carbon, etc., resulting from the distillation are collected.
—W. P. S.

Sewage and other mixtures of liquids and solids; Centrifugal treatment of —— and apparatus for use in connection therewith. J. Bromet, F. Thorman, and H. C. Wood, Tadcaster, Yorks. Eng. Pat. 1085, Jan. 15, 1914. Addition to Eng. Pat. 22,836, Oct. 7, 1912 (this J., 1913, 839).

The liquid is passed down a pipe reaching to the bottom of the centrifugal drum and thence passes upwards through the annular separating chamber, the separating process being thus carried out in the reverse direction to that described in the previous patent (*loc. cit.*). The liquid is discharged tangentially from the drum.—W. P. S.

Filter beds for sewage and other waste liquids. I. K. Irwin, London Eng. Pat. 3392, Feb. 9, 1914.

Movable screens are fitted between the distributors and the surface of the filter-bed with the object of intercepting the solids in suspension in the liquid. A layer of coke or sand, to which chemical agents may be added, may be placed on the upper side of the screen.—W. P. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Quinine-benzene; The T,x-diagram of the system ——. J. W. van Iterson-Rotgans. Z. physik. Chem., 1914, **87**, 305—322.

In extracting cinchona bark with benzene according to van Leersum's method, the solubility of quinine in the boiling solvent was found to be much greater than that stated in the literature (1 part of quinine in 30 of boiling benzene according to Oudemans, Arch. Neerl., 1877, **9**, 285). Experiments were made from which the complete m. pt. curve of mixtures of benzene and quinine was plotted. Vapour pressure determinations were also made, and it is concluded that benzene and quinine form two compounds, $C_{20}H_{24}N_2O_2,C_6H_6$ and $3C_{20}H_{21}N_2O_2.2C_6H_6$, of which the latter forms mixed crystals with quinine. The first-named compound crystallises in two forms, *viz.*, as needles and as rhombohedra (see Oudemans, *loc. cit.*). Over a wide range of the system also, a colloid-like solid phase is formed having a refractive index identical with that of the solution. This behaves as a homogeneous mixed phase and is probably either a colloid or a highly viscous solution. Preliminary determinations of the solubility of quinine in boiling benzene gave varying results higher than corresponded with the curve, and this was found to be due to lag in the formation of the colloid-like solid phase, whereby the compound, $C_{20}H_{24}N_2O_2,C_6H_6$, dissolved to a metastable solution, from which a portion of the dissolved quinine would again separate, but only with extreme slowness, even in contact with the colloid-like solid. By adopting certain precautions to overcome this difficulty, the true solubility was found to be 1 part of quinine in 4·56 parts of boiling benzene, the saturated boiling solution thus containing 18% of quinine. The author is unable to explain the low result of Oudemans (*loc. cit.*); under ordinary conditions results higher than the true values are to be expected.—A. S.

Quinine derivatives; Investigations of certain ——. K. Schroeder. Arch. exp. Pathol. u. Pharmakol., 1913, **72**, 361. Chem.-Techn. Rep., 1914, **38**, 3.

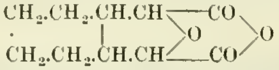
Against infusoria and plasmodia, monobromoquinine and quinine dibromide were twice as effective as quinine, dehydroquinine was only half as effective, and cupreine dibromide was practically inactive. The relative actions towards bacteria were similar but weaker, and towards frog-spawn the differences were even more strongly marked.—O. R.

Isostrychnine; Pharmacodynamic action of ——. M. B. Wiki. L'Union Pharm., 1914, **55**, 341. Pharm. J., 1914, 667.

Isostrychnine was obtained by Bacovescu and Pictet (this J., 1905, 1123) by heating strychnine and water in sealed tubes to 160°—180° C. It has the same ultimate chemical formula as strychnine, $C_{21}H_{22}N_2O_3$; but crystallises in a different form with 3 mols. H_2O and melts at 214·5° C. The author finds it to be much less poisonous than strychnine. In toxicity it approaches brucine. The action on the nervous system more closely resembles that of curare than of strychnine, and doses which kill by arresting respiration do not affect the cardiovascular system. Its tetanising action is slight, and only seen under certain conditions. Pharmacologically, isostrychnine is placed between curare and brucine.

Cantharidin. J. Gadamer. Ver. Ges. deuts. Naturforsh. Aerzt., 1913—1914, II., 494. J. Pharm. Chim., 1914, **10,** 343—344.

The following symmetrical formula is assigned to cantharidin :—



When heated with a solution of hydrobromic acid in acetic acid, compounds of the composition, $C_{10}H_{12}O_3Br_2$ and $C_{10}H_{11}O_3Br$, are produced together with hydrobromocantharic acid, $C_{10}H_{13}O_4Br$. The latter was resolved into optically-active isomerides by means of brucine. The active acid when reconverted into cantharidin gave an inactive product.—F. Shdn.

Gentiacaulin. M. Bridel. J. Pharm. Chim., 1914, **10,** 329—335. (See this J., 1913, 958.)

The roots and leafy twigs of *Gentiana acaulis* were extracted separately, and biochemical tests indicated that both portions of the plant contained the same glucoside hydrolysable by emulsin, the twigs having a greater content than the roots. The actual yields, however of gentiacaulin were 2% for the fresh roots and 1% for the fresh leafy twigs. The glucoside was found to have $[a]_D = -64{\cdot}42°$ instead of $-63{\cdot}84°$ as stated formerly (*loc. cit.*). When hydrolysed by boiling with 2% sulphuric acid gentiacaulein, dextrose, and xylose were formed in equivalent proportions.—F. Shdn.

a-Methyl-glucoside ; Influence of alcoholic strength upon the biochemical synthesis of —— by a-glucosidase. A. Aubry. J. Pharm. Chim., 1914, **9,** 19—23. (See also this J., 1914, 982.)

The fermenting liquid consisted of 20% of filtered yeast maceration juice and 1% of dextrose. The proportion of methyl alcohol in the fermenting liquid varied from nil to 40%. When the alcohol was insufficient to prevent growth of bacteria, 2% of toluene was added. Fermentation was conducted at 18°—20° C., and polarimeter readings were taken every 4 days until the reaction was complete. Even with only 2% of methyl alcohol, 12·4% of the dextrose was combined. The synthesis increased with increase of alcohol up to 16% after which it diminished to zero. At 36% of alcohol, when destruction of the enzyme by the alcohol was immediate, no new synthesis took place. The influence of temperature was important, the destructive influence of the alcohol increasing rapidly at higher temperatures ; its influence was immediate with 16% of alcohol at 40° C. a-Glucosidase is more active than emulsin under the same conditions.—J. H. J.

Plant chemistry ; Notes on ——. P. Q. Keegan. Chem. News, 1914, **110,** 211—212.

An extract of grass of Parnassus (*Parnassia palustria*), made with boiling water, contained a moderate amount of mucilage and no nitrate. It gave reactions of a tannoid, probably rutin, and also of a catechol tannin (2—3%). Butterwort (*Pinguicula vulgaris*) contained no nitrate and no tannin, but considerable quantities of mucilage, sucrose, and a tannoid apparently resembling quercitagenin and associated with a catechin-like substance. Golden saxifrage (*Chrysosplenium*) yielded much mucilage, some gum and sucrose, a little nitrate and tannin (a true catechol without any pyrogallol derivative) but no tannoid ; there was also present a substance with a quinol group (1 : 4). Leaves of mahonia or holly-leaved barberry resembled those of common ivy, in containing caffetannin and a tannoid, probably quercitagenin, and in giving certain reactions, *e.g.*, aqueous extracts, on addition of dilute alkalis, produced a fine green coloration tending to become brown, and reddened by acids—a reaction rare in plant chemistry. The monkey flower (*Mimulus luteus*), an immigrant from Western America, contained nitrate, about 1% of caffetannin, a bitter principle soluble in benzene and in sulphuric acid with purplish colour, an unknown substance yielding a green coloration and precipitate with acetic and hydrochloric acids, but no rhenanthin or tannoid. Very small quantities of caffetannin were detected in the leaves of the day-lily and the turk's head or martagon lily.

Analyses of forest leaves at different stages of growth revealed the fact that in the young leaf tannoids alone are frequently produced, and only later do tannins appear. The tannoids thus seem to be products of alkaline protoplasm, and they are associated with volatile oils, resins and waxes, whilst the tannins are associated with organic acids, especially oxalic acid.—J. H. L.

Cinnamon ; Composition of ——. F. W. Dafert and R. Miklauz. Archiv Chem. u. Mikrosk., 1912, **5,** 117—120 ; Z. Unters. Nahr. Genussm., 1914, **28,** 42.

Ten samples of Ceylon cinnamon (*a*) and 16 samples of cassia-cinnamon (*b*) yielded the following results when dried for 2 hours at 100° C. and then extracted in a Soxhlet apparatus for 10 hours with 90% alcohol :—Loss at 100° C. (water and volatile oil), (*a*) 8·33—11·90% ; (*b*) 8·29—12·23% ; non-volatile alcohol-extract, (*a*) 12·09—17·14% ; (*b*) 6·41—18·66%. In the case of Ceylon cinnamon the sum of these two values lay between 20·42 and 26·07% and with cassia-cinnamon between 17·94 and 29·47%.
—W. P. S.

Sandalwood oil and its application to perfumery. H. Mann. Amer. Perfumer and Essent. Oil Rev., 1914, **9,** 213—214.

Fine scents for soaps are prepared by mixing 5 parts of sandalwood oil with 3 parts of natural or artificial rose oil or Bourbon geranium oil, and 1 part of coumarin. A further addition of ½ part of patchouli oil and 5 parts of concentrated infusion of benzoin can be made. The soap-mass becomes coloured light-brown or dark-gray. The perfume can be fixed by the addition of a small quantity of artificial musk. Cedar-wood oil is substituted for sandalwood oil in some cases. Variations can be obtained by the use of residues from the distillation of orris root and the addition of small quantities of vanillin. Handkerchief perfume can be made with infusion of oil of rose as a base treated with small additions of violet and orange concretes, sandalwood and French geranium oils being then added with oil of bergamot and infusion of genuine musk. Sachets and powders are made from the ground wood mixed with orris and vetiver roots. Amongst other causes of the fluctuating price of sandalwood oil is the fact that the trees suffer at times from a malignant disease.
—F. Shdn.

Cardamoms and cardamom oil. G. M. Beringer. Midl. Drug. and Pharm. Rev., **46**; through Z. Unters. Nahr. Genussm., 1914, **27,** 902—903.

Commercial cardamom oil is derived mainly from the cultivated cardamoms (seeds of *Elettaria Cardamomum* White and Maton) of Ceylon and Malabar, and possesses a sp. gr. of 0·929—0·947, and a rotatory power ranging from +22·2° to +40° at 25° C. Oils of lower density and rotatory power are from other or wild cardamoms, and should be rejected. The pure oil, like most other essential oils, keeps well, and dissolves when fresh in 3 vols. of 70% alcohol, and when somewhat aged, in 4 vols. (See also Reinsch, this J., 1911, 139 ; and this J., 1911, 293.)—J. H. L.

Essential oils ; Constants of various ——. Sci. and Ind. Bull. of Roure-Bertrand Fils. Z. Unters. Nahr. Genussm., 1914, **27,** 686—687.

Essential oil of Nepeta nepetella. Plants collected in September after blooming yielded 0·0598% of a yellow, rather viscous essential oil having the following characters : sp. gr. at 20° C., 1·03984, at 32° C., 1·02536 ; optical rotation +15° 12′ and after acetylation, +17° 20′ ; acid value, 45·5 ; ester value, 245·7 and saponification value, 314·5. The oil is soluble in 2 vols. of 70% alcohol and gives no coloration with ferric chloride. Only a part of the oil combines with sodium bisulphite. *Ylang-ylang oil from Mayotte.* Two samples gave the following characters: sp. gr. at 15° C., 0·9594 and 0·9651; optical rotation, —53° 56′ and —45° 16′; acid value, 1·3 and 1·4; ester value, 129·7 and 131·6; ester content calculated as $C_{10}H_{17}.CO_2CH_3$, 45·4% and 46·0%; saponification value of the acetylated oil, 167·0 and 180·8; total alcohol content, calculated as $C_{10}H_{18}O$, 52·5% and 57·5%. The oils were soluble in one volume of 95% alcohol, the solutions becoming turbid on the addition of more alcohol. A third sample of this oil had an optical rotation of —4° 4′. *Oil of Cape* (see this J., 1912, 149).—T. C.

Calycanthus floridus; Volatile oil of ——. E. R. Millor, G. W. Taylor, and M. H. Eskew. J. Amer. Chem. Soc., 1914, **36**, 2182—2187.

Oil of *Calycanthus floridus*, separated from the stem and bark by steam distillation, was found to contain *d*- and *l*-α-pinene, cineol, borneol, bornyl acetate and other esters, salicylic acid, and probably linaloöl. The cineol predominated, 36 and 69% being present in different samples.—F. Sodn.

Essential oils and essential oil products; Hydrogen number of some ——. *I. Oils of sassafras, anise, fennel, clove, and pimento.* A. R. Albright. J. Amer. Chem. Soc., 1914, **36**, 2188—2202.

The method depends on the quantitative hydrogenation of unsaturated compounds in presence of a solution of colloidal palladium as prepared from the commercial dry product or by the process of Paal and Amberger (this J., 1904, 208). The "hydrogen number" of the oil is the number of c.c. of hydrogen, at standard temperature and pressure, absorbed by 1 grm. during the period of primary or most rapid absorption. Dry colloidal palladium (0·02 grm.) and 50 c.c. of 50% alcohol are introduced into an absorption flask of special design, which is filled with hydrogen through an attached gas burette, and the flask is closed and mechanically shaken until hydrogen is no longer absorbed; it is then opened and the substance allowed to drop from a weighing bottle on to a concave "substance table" within the flask, while a current of hydrogen is passed through the apparatus, and finally the flask is again shaken until an abrupt decrease in the rate of absorption, as registered by the burette, is observed (preferably by means of a curve). An appropriate factor converts the burette reading into the % of active constituent (*e.g.*, eugenol) present. The paper deals only with oils of the type that can be completely and very rapidly reduced, and a table is given showing the hydrogen numbers of various samples of sassafras, anise, fennel, clove, and pimenta oils. Oils containing substances "poisonous" to colloidal palladium (*e.g.*, mustard oil) cannot be treated by the process.—F. Sodn.

N-Methyl-α-acetylindole. O. Diels and W. Dürst. Ber., 1914, **47**, 284—290.

N-Methyl-α-acetylindole,  $C_6H_4\begin{matrix}—CH\\N(CH_3)\end{matrix}C.CO.CH_3$, obtained by condensation from diacetylmonomethylphenylhydrazone, $CH_3.CO.C[:N.N(CH_3)(C_6H_5)].CH_3$ (Ber., 1911, **44**, 263), has a physiological action similar to that of morphine, but is only slightly soluble in water. By subjecting the nitro-compound of diacetylmonomethylphenylhydrazone to the indole condensation, 3-nitro-N-methyl-α-acetylindole, was obtained, and this, on reduction with zinc dust in moist ethereal solution, gave the corresponding amino-compound,  $NH_2.C_6H_3\begin{matrix}CH\\N.CH_3\end{matrix}C.CO.CH_3$. The latter formed soluble salts but these were quite devoid of physiological action. The amino-compound when diazotised and combined with R-salt gave a red azo dyestuff.—A. S.

Hydramine-ethers and hydramines; Method for the preparation of —— *and of compounds of the choline series.* J. Houben and K. Führer. Ber., 1914, **47**, 75—82.

The authors have shown previously (Ber., 1907, **40**, 4990) that when dichloro-ethyl ether is brought into contact with ethereal organomagnesium halides, the α-chlorine atom is replaced by an alkyl or aryl group, whilst the β-chlorine atom remains intact:

$$C_2H_5O.CHCl.CH_2Cl + R.Mg.hal. = C_2H_5O.CHR.CH_2Cl + Cl.Mg.hal.$$

The second chlorine atom can be replaced by heating the resulting alkylated glycol chlorhydrin ethers with alkalis or amines. With the fixed alkalis, hydrochloric acid is withdrawn and unsaturated ethers are formed: $C_2H_5.O.CHR.CH_2Cl—HCl = C_2H_5.O.CR:CH_2$. With ammonia or primary amines a mixture of products is obtained. Phenyl-glycolchlorhydrin ether, $C_2H_5.O.CH(C_6H_5).CH_2Cl$, for example, with alcoholic ammonia, yielded chiefly β-ethoxyphenylethylamine, $C_6H_5.CH(OC_2H_5).CH_2.NH_2$, and di-[β-ethoxyphenylethyl]-amine, $[C_6H_5.CH(OC_2H_5).CH_2]_2NH$. With dialkylamines the halogen of the glycolchlorhydrin ether is replaced by the dialkylamine-residue, ethyl-glycolchlorhydrin ether and diethylamine, for example, yielding N-diethyl-2-ethoxybutylamine: $C_2H_5.O.CH(C_2H_5).CH_2Cl + NH(C_2H_5)_2 = HCl + C_2H_5.O.CH(C_2H_5).CH_2.N(C_2H_5)_2$. N-Diethyl-2-ethoxyisohexylamine, N-diethyl-2-ethoxyisoheptylamine, and N-diethyl-2-ethoxy-2-phenylethylamine were prepared in an analogous manner. By the action of strong hydrobromic acid, the ethoxy group can be replaced by hydroxyl, yielding compounds which possess considerable physiological interest and are of importance as materials for the synthesis of substances of the choline and adrenaline series.—A. S.

Hydrogenation of compounds with aliphatic ethylenic linkages in the presence of nickel under moderate pressure. A. Brochet and M. Bauer. Comptes rend., 1914, **159**, 190—192. J. Chem. Soc., 1914, **106**, i., 1069.

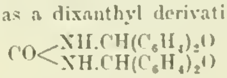
Using the method already described (compare Brochet, this J., 1914, 612) the authors have hydrogenated a number of aromatic compounds containing an ethylenic linkage in the side-chain and one aliphatic compound. Δ^1-Octene readily yields octane. Cinnamic acid, its sodium salt and its methyl ester yield phenylpropionic acid and its corresponding derivatives. The hydrogenation proceeds better with the sodium salt than with the free acid. Piperonylacrylic acid hydrogenates less readily than cinnamic acid, but the conversion readily takes place on using the sodium salt. Anethole, eugenol, and safrole readily undergo hydrogenation at 60°—80° C., whilst for *iso*eugenol the ordinary temperature suffices.

Hydrogenation under atmospheric pressure in the presence of nickel of compounds with aliphatic ethylenic linkages. A. Brochet and A. Cabaret. Comptes rend., 1914, **159**, 326—329. J. Chem. Soc., 1914, **106**, i., 1069.

The substances containing aliphatic ethylenic linkages which were hydrogenated in the presence of active nickel under a slightly increased pressure by Brochet and Bauer (see preceding abstract) also undergo hydrogenation under atmospheric pressure, but in this case the reaction takes place far more slowly and requires a larger amount of the catalyst.

Urea; Quantitative gravimetric determination of ——. R. Fosse. Comptes rend., 1914, **158**, 1076—1079.

A new method for the determination of urea depends on its precipitation as a dixanthyl derivative,



$$CO<\begin{matrix}NH.CH(C_6H_4)_2O\\NH.CH(C_6H_4)_2O\end{matrix}$$

by means of xanthydrol. The urea solution is diluted with 3·5 vols. of glacial acetic acid, and 0·5 vol. of a 10% solution of xanthydrol in methyl alcohol is added, preferably in five portions at intervals of 10 minutes. After one hour the crystals are collected, washed with alcohol, dried, and weighed. The results with 0·5% solutions were about 1% low, whilst for 0·2% solutions they were from 1—2% high. This is due to the precipitate containing a small proportion of xanthydrol as impurity at the lower concentrations; when pure 6·66% of its weight represents urea nitrogen.—G. F. M.

Xanthydrol; Chemical activity of ——, and its application to the determination of urea. R. Fosse. Comptes rend., 1914, **158**, 1432—1435. (Compare preceding abstract.)

Although xanthydrol possesses considerable chemical reactivity towards a large variety of substances, it does not precipitate from acetic acid solutions, under the conditions employed, any of the biological products likely to be contained in urine, other than urea. In addition to xanthyl derivatives previously described, condensation products with the following substances frequently met with in biochemical work have now been prepared and characterised: phenylurea, urethanes, biuret, malonamide, succinamide, pyrrole and its derivatives, and dimethylaniline.—G. F. M.

Urea; Gravimetric determination of —— at dilutions greater than 1 in 1000. R. Fosse. Comptes rend., 1914, **159**, 253—256. (See also preceding abstracts.)

The xanthydrol method for the estimation of urea in pure aqueous solution or in urine is equally applicable for the determination of small quantities of the order of 0·002 grm. if the following procedure be adopted. One vol. of the solution, exactly measured, is diluted with 2 vols. of acetic acid, and 0·05 vol. of a solution of xanthydrol in methyl alcohol is added at intervals of ten minutes, the addition being made three times. After one hour the crystals are collected and weighed. A large number of determinations made with solutions of varying strengths showed that the method is reliable.—G. F. M.

Urea; A method of determining ——. A. Desgrez and R. Moog. Comptes rend., 1914, **159**, 250—253.

A modified form of ureometer is described (see Comptes rend., 1911, **153**, 1007) by means of which an accurate gasometric determination of urea can be made in from 40 mins. to 1 hour. It consists of a U-tube, the shorter arm of which is open at the end and expanded into a bulb, and the longer arm is graduated and fitted with a tap and extension tube for introducing the reagents. It is charged successively with chloroform, the urea solution, and a reagent consisting of a mixture of equal volumes of a solution of 50 grms. of mercury in 100 grms. of cold nitric acid (sp. gr. 1·3322), and an aqueous suspension of infusorial earth. The latter, which is prepared by shaking 1 grm. of the earth with 100 c.c. of water, allowing to settle a minute, and decanting, acts as a catalyst, and enables the decomposition of the urea to proceed quantitatively at 17° C. After the decomposition of the urea, which is assisted by careful shaking from time to time, is complete, the carbon dioxide is washed out of the resulting gases first with 150 c.c. of water and then with a small quantity of potash solution, and the residual gas is measured after first adjusting the chloroform levels in the ureometer. Since none of the other nitrogenous constituents of urine are decomposed, except allantoin, and that very slowly (0·015 grm. in 24 hours), the method is suitable for the analysis of urine, serum, etc.—G. F. M.

Acetosalicylic acid. H. von Krannichfeldt. Ber., 1914, **47**, 156—159.

The acetosalicylic acid prepared by Bialobrzeski and Nencki in 1897 (Ber., **30**, 1776) and which, unlike salicylic acid, has only a slight antiseptic action, yielded chiefly *p*-hydroxyacetophenone when distilled with quicklime and hence must have the constitution:

$$C_6H_3(OH)(COOH)C_2H_3O[COOH : OH : C_2H_3O = 1 : 2 : 5].$$

Some phenol also was formed, and by distilling *p*-hydroxyacetophenone with lime, a yield of about 15% of the theoretical quantity of phenol was obtained. The ethyl ester of acetosalicylic acid, m. pt. 70°—71° C., the methyl ether, m. pt. 152° C., and the ethyl and methyl esters of the methyl ether, m. pts. 41°—42° C. and 96° C. respectively, were prepared. Acetosalicylic acid yielded no acetosalicylacetic acid when heated with monochloroacetic acid and sodium hydroxide (Meyer, Ber., 1913, **46**, 3266), but gave this acid, $C_2H_3O.C_6H_3(COOH)O.CH_2.CO_2H$, m. pt. 179° C., although in poor yield, when the sodium hydroxide was replaced by potassium hydroxide.—A. S.

Glycerol: Esterification of —— by acetic acid in the presence of catalytic agents. J. B. Senderens and J. Aboulenc. Comptes rend., 1914, **158**, 581—583.

When glycerol (1 mol.) was boiled for 1 hour with glacial acetic acid (3 mols.), 0·4 mol. of the acid was esterified. In presence of 15 grms. of potassium bisulphate 1·2 mols. were esterified; whilst in the presence of 2% anhydrous aluminium sulphate or 1% sulphuric acid, the respective amounts were 1·3 and 1·5 mols. Complete esterification of 1 mol. of glycerol was effected by boiling for 1 hour with 12 mols. of acetic acid in presence of 1% of sulphuric acid. The limits of esterification of 1 mol. of glycerol by boiling with 3 or 6 mols. of acetic acid in presence of a catalytic agent were practically reached in 1 hour. (See also this J., 1911, 830, 922.)—C. A. M.

dl-Glyceric aldehyde from a syrup obtained by the oxidation of glycerol; Isolation of crystalline ——. E. J. Witzemann. J. Amer. Chem. Soc., 1914, **36**, 2223—2234.

The reaction mixture obtained by oxidising glycerol with hydrogen peroxide in the presence of ferrous iron (Fenton and Jackson, Chem. Soc. Trans., 1899, **75**, 4) was proved to contain *dl*-glyceric aldehyde by converting this into the acetal, extracting with ether, and hydrolysing with very dilute sulphuric acid. Inoculation of the final syrup gave crystals of the pure compound.—F. Sodn.

Carvacrol ethers; Preparation of ——. P. Sabatier and A. Mailhe. Comptes rend., 1914, **158**, 608—612.

Carvacrol vapour passed over thorium oxide at 400°—500° C. gave on condensation a yellowish fluorescent liquid which, after removing unaltered carvacrol with caustic soda, distilled at about 330° C. and consisted of a mixture of *dicarvacryl oxide*, $(C_{10}H_{13})_2O$, and *dicarvacrylene oxide*,

$$\begin{array}{l} C_{10}H_{12} \\ | \\ C_{10}H_{12} \end{array}\!\!>\!O.$$

A mixture of carvacrol and methyl alcohol passed over thorium oxide at 420°—450° C. gave a yellow fluorescent liquid which was fractionated into carvacrol methyl ether, b. pt. 217° C., and dicarvacryl oxide, crystallising in small prisms, m. pt. 109°—110° C., insoluble in water but soluble in most organic solvents. When the reaction was carried out at about 480° C., dicarvacrylene oxide was also obtained and formed white crystals with a yellowish fluorescence, m. pt. 150° C., and only very sparingly soluble in cold alcohol. Ethyl alcohol substituted for methyl alcohol in this reaction gave only a small amount of carvacrol ethyl ether and an oily fluorescent liquid which could not be crystallised. A mixture of carvacrol and phenol distilled over thorium oxide at 470°—480° C. gave a liquid which after removal of unaltered phenols with caustic soda, yielded *carvacrol phenyl ether*, b. pt. 296° C., dicarvacryl oxide and dicarvacrylene oxide. No diphenyl ether or diphenylene oxide was obtained. A mixture of carvacrol and *p*-cresol gave at 440°—450° C. under similar conditions, *carvacrol-p-cresyl ether*, b. pt. about 300° C., and *di-p-cresyl ether*, m. pt. 50° C., b. pt. 285° C. At 480° C. the chief products were di-*p*-cresyl ether and *di-p-cresylene oxide*, m. pt. 166° C.—T. C.

Boiling points; Method of determining —— in the British Pharmacopœia, 1914, and its relation to the boiling point of ether. H. Finnemore. Pharm. J., 1914, **93**, 584.

In the 1914 edition of the British Pharmacopœia the effect of superheating and of changes of barometric pressure are ignored, although the much smaller correction for emergent stem of the thermometer is mentioned. Superheating is corrected by wrapping a thin layer of cotton-wool, upon which some of the liquid condenses, round the thermometer bulb. With this precaution a sample of ether distilled between 34·5° and 34·9° C., whereas under Pharmacopœial conditions it distilled between 34·5° and 37° C.—O. E. M.

Aldehydes; Catalytic decomposition of ——. M. Kusnetzow. J. Russ. Phys. Chem. Ges., 1913, **45**, 557—568. Chem.-Techn. Rep., 1914, **38**, 15—16.

The formation of carbon monoxide and hydrogen in the oxidation of methyl alcohol can be so limited by the use of metallic silver as catalyst, as to result in a 70% yield of the theoretical amount of formaldehyde; the decomposition of the aldehyde group with formation of carbon monoxide is a general property of aldehydes, palladium black acting most energetically as a catalytic agent.—O. R.

Hydrochloric acid; Catalytic influence of ——, *upon esterification in mixed solvents.* A. Kailan. Z. physik. Chem., 1914, **86**, 65—102.

The esterification of benzoic acid under the catalytic influence of hydrochloric acid in alcoholic and aqueous alcoholic solutions was appreciably retarded by the addition of ether, benzene, or carbon tetrachloride: this being the order of decreasing effect. The retarding influence of water in such mixtures increased successively in the following series: ether-alcohol, benzene-alcohol, carbon tetrachloride-alcohol. From the analogous results obtained by the addition of benzene to similar solutions of succinic, malic and tartaric acids it is concluded that the esterification of these acids occurs in stages rather than as a trimolecular reaction. Esterification in such mixtures is represented as a reaction of the first order.—J. R.

Alcohol; Action of hydrochloric acid upon ——. S. Kilpi. Z. physik. Chem., 1914, **86**, 427—444.

The reaction-velocity between hydrochloric acid and alcohol in aqueous solution was investigated at 97°, 102° and 110° C., the solutions containing 46·2% of alcohol and acid corresponding to strengths of 0·25, 0·5 and 1·0 *N*, respectively. The effect of adding ammonium chloride was also ascertained. The results point to the reaction occurring wholly between alcohol and undissociated hydrochloric acid, the effect of the ionised acid being negligible. Increase of temperature displaced the equilibrium in the forward direction; and the results are in accordance with Arrhenius' equation:

$$\log K_1 - \log K_2 = a\frac{T_1 - T_2}{T_1 - T_2},$$

where K_1 and K_2 are the reaction velocities at the temperatures (abs.) T_1 and T_2 respectively and a is the temperature coefficient.—J. R.

Bismuthated oil of vaseline. A. Vicario. J. Pharm. Chim., 1914, **9**, 458—459.

The unpleasant after-effects of large doses of bismuth subnitrate due to the formation of nitrites, as well as those due to to the solubility of bismuth oxide and carbonate in dilute acids, can be avoided by administering these drugs intimately triturated with oil of vaseline. Bismuth carbonate intimately triturated with oil of vaseline is not attacked even by concentrated hydrochloric acid.—T. C.

Mercuric iodide and aniline; Equilibrium in the system ——. J. N. Pearce and E. J. Fry. J. Phys. Chem., 1914, **18**, 667—676.

The system was studied over the temperature range from —11·48° to 181° C. At —11·48° C. an eutectic mixture of aniline and $HgI_2,2C_6H_5NH_2$ separates. With rising temperature, the solubility of the mercuric iodide increases gradually up to about 10° C. and then more rapidly up to 46·8° C., when a white compound, $HgI_2.2C_6H_5NH_2$, m.pt. 58·6° C., is in equilibrium with the saturated solution. Between 46·8° and 108° C. the solubility increases rapidly and linearly, and the solid phase is red mercuric iodide, the transition point to the yellow iodide being 108° C. in presence of aniline. Above 108° C. the solubility of the yellow iodide increases but slightly with rise of temperature, and a new solid phase, $Hg_2I_2,C_6H_5NH_2$, appears as a greenish-yellow, flaky, mica-like solid. The solubility of mercuric iodide expressed as grms. HgI_2 per 100 grms. of aniline, at different temperatures was:—6·5° C., 23·35; +0·4°, 28·69; 17·8°, 42·85; 21·1°, 47·55; 26·9°, 55·47; 30·1°, 62·05; 36·2°, 75·80; 42·9°, 96·49; 48·8°, 128·1; 63·6°, 163·8; 70·8°, 184·1; 76·2°, 201·6; 95·9°, 246·7; 115·7°, 281·8; 137·2°, 285·2; 181·1°, 297·9. To determine mercuric iodide in the presence of the easily oxidisable aniline, the sample was dissolved in a solution of acetic acid containing an excess of potassium iodide, and the mercury precipitated with hydrogen sulphide, the precipitate being washed with water and alcohol, dried, extracted with carbon bisulphide to remove free sulphur, and dried to constant weight at 70° C. (mercuric sulphide loses weight appreciably when heated at 110° C., as recommended by Treadwell and Hall, "Analytical Chemistry," 3rd Ed., Vol. II., p. 169).—A. S.

Chloro-derivatives of methane; Absorption of ultra-violet rays by the ——. G. Massol and A. Faucon. Comptes rend., 1914, **159**, 314—316. J. Chem. Soc., 1914, **106**, ii., 695.

The authors have examined three specimens of carbon tetrachloride having respectively b. p. 76·2° C./762·4 mm., 76° C./758 mm., 76·7° C./760 mm. Of these, the first two specimens gave broad absorption bands in the ultra-violet, whilst the third showed no absorption band. Specimen 2 was then submitted to fractional distillation, and a number of fractions were obtained boiling from 61·4° to 76·3° C., all of which showed an absorption band. A final fraction was obtained, b. p. 76·4° C./758 mm., which gave no absorption band, and was shown to be pure carbon tetrachloride. The others contained carbon bisulphide as an impurity, and this produced the absorption band.

Neither chloroform nor dichloromethane gave absorption bands in the ultra-violet. All three chloro-derivatives are colourless, and transparent to the visible and ultra-violet rays, only absorbing the rays of very short wave-length. The transparency for the latter rays diminishes as the number of chlorine atoms in the molecule increases.

Patents.

p-Phenetidine; Preparation of acyl derivatives of ——. P. Bergell. Ger. Pat. 277,022, Sept. 17, 1912.

p-Phenetidine is converted into its α-bromo-isovaleryl derivative, for example by treatment with bromo-isovaleryl bromide in presence of benzene. A product of m.pt. 151° C. is obtained, in which the physiological properties of the components are apparent.—T. F. B.

Acidyl derivatives of C-ortho-allyl-ortho-benzoic acids. L. Taub and H. J. Hahl, Elberfeld, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pat. 1,113,713, Oct. 13, 1914. Date of appl., Dec. 20, 1913.

See Ger. Pat. 274,047 of 1913; this J., 1914, 806.—T. F. B.

Apocynaceæ; Substance isolated from ——, *and process of producing the same.* L. Taub and G. Fickewirth, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,113,714, Oct. 13, 1914. Date of appl., Sept. 4, 1912.

See Ger. Pat. 255,537 of 1911; this J., 1913, 450.—T. F. B.

Acetic anhydride; Process of manufacturing ——. W. A. Beatty, Assignor to G. W. Beadle, New York. U.S. Pat. 1,113,927, Oct. 13, 1914. Date of appl., April 30, 1912.

See Fr. Pat. 447,646 of 1912; this J., 1913, 253.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photochemical properties of coloured resinates. Larguier des Bancels. *See* XIII.

Patents.

Cinematograph films; Manufacture of ——. H. Jerne, Merton Abbey. Eng. Pat. 22,234, Oct. 2, 1913.

A protective film of transparent celluloid is attached to the emulsion surface of a finished cinematograph film by means of amyl acetate or other solvent or adhesive. —T. F. B.

Colour photography and colour printing. J. and E. Rheinberg, London. Eng. Pat. 22,938, Oct. 10, 1913.

A negative or positive is taken in the usual manner through a multicolour screen composed of lines or dots of the "additive" colours, red, green, and violet; this is now printed on a viewing screen coated with a sensitised colloid, the screen being similar to that first employed, excepting that the "subtractive" colours (minus red, minus green, and minus violet, *i.e.*, greenish-blue, magenta, and yellow) are used: the screen must be in exact register with the positive, *i.e.*, minus red registering with red, and so on. The sensitised colloid layer is now developed and the screen is treated with a solvent which will dissolve the colours from under the colloid according to the amount of light action. For example, when albumin is the colloid used and the colour screen is made of collodion, an alcoholic solvent is suitable. In the picture thus obtained the image is composed of separate dots of colour; treatment with a solvent of the dyestuffs results in the colours of the dots intermingling: thus, a red object would first be represented by magenta, yellow, and colourless areas, which when blended would appear red. The finished picture may now be transferred or applied to paper. A number of variations of this process are described, but all involve the intermingling of the separate colour areas of the final print, either by the action of solvents or by heat or moisture. Multicolour prints made by successively printing coloured lines, dots, or patches over one another, are frequently somewhat out of register, with the result that portions of the constituent colour areas are seen separately: this may be corrected by treating the prints with a solvent of the inks or pigments used, or of the vehicle, *e.g.*, turpentine or a solution of caustic soda, or by applying heat or pressure sufficient to cause the colours to run or spread to a slight extent.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Explosibility of mixtures of air and ammonia. Schlumberger and Piotrowski. *See* VII.

Patents.

Blasting or exploding by liquid air, oxygen or like suitable liquefied gas or medium of low temperature. O. Simonis, Walthamstow, Essex. Eng. Pats. 24,137, Oct. 24, 1913, and 10,178, April 24, 1914.

The explosive mixture is produced by bringing liquid air or oxygen into contact with absorbent material, such as charcoal, kieselguhr, etc., impregnated with paraffin oil, just prior to the firing of the charge by a detonator, and the walls of the shot-hole are given a preliminary low cooling. The liquid air may be placed in a double-walled container made in two parts, fitting together telescopically, so that the cold evaporated air passing between the walls serves as a heat insulator. The container is embedded in the absorbent material, and the two parts are held together by means which can be broken automatically when a certain pressure is developed within the cartridge. In alternative forms, both the absorbent material and the liquid air are placed in a double-walled container, or the cartridge of liquid air may be placed in the absorbent material in an outer vessel, the liquid air vessel having a detachable flap which may be removed or torn by means manipulated outside the shot-hole.—B.N.

Explosives; Process of varying the velocity of detonation of ——. C. A. Woodbury, Chester, Pa., Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,113,275, Oct. 13, 1914; date of appl., May 18, 1912. Renewed March 2, 1914.

The velocity of detonation of explosives containing ammonium nitrate may be decreased by increasing the size of the grains of ammonium nitrate or increased by decreasing the size of the grains.—B. N.

XXIII.—ANALYTICAL PROCESSES.

Thermo-elements of precision, especially for calorimetry. W. P. White. J. Amer. Chem., Soc., 1914, **36**, 2292—2313.

The quality of constantan ("ideal") wire for thermoelements has now been so improved that continuous lengths are frequently obtainable which vary less than 0·0002 in E.M.F. against copper, and with which sensitive thermoelements with errors usually less than 20 per million can be made. The more sensitive combination of several couples is recommended in preference to a single couple, even when great precision is not required. Details of testing the wire, constructing, enclosing, calibrating and testing the thermo-elements are given. For testing the homogeneity of the wire, it is drawn out of a heated bath, for example wound from one drum in a heated bath on to another outside the bath and the different portions of the wire tested as they are drawn successively out of the bath. Inhomogeneous portions of the wire are either cut out or are so placed in the thermoelement that they do no harm. Inhomogeneity causes errors only in the case of that portion of the thermoelement where the effective temperature gradient occurs; even a very bad portion of wire will not cause any inconvenience if it is 5 cm. below the level of the bath at either end of the thermoelement when this is in use. For insulating the junctions an unpublished method of L. H. Adams is recommended. The junction is dipped into a fairly thick solution of pure gum rubber in a mixture of benzene and carbon bisulphide, dried, and the rubber vulcanised by immersion for a few seconds in a solution of sulphur dichloride in carbon bisulphide (1 : 40) and dried at 40°—50° C. A harder coating may be obtained by using a mixture of rubber solution with 20% (of the weight of rubber) of precipitated sulphur, and vulcanising by heating at 130°—150° C. Cellulose acetate solution is the best of the insulating varnishes. To diminish lag the junctions after insertion in the glass or metal case are embedded in paraffin wax or naphthalene.—A. S.

Hydrochloric acid solutions; Method for the precise standardisation of ——. L. W. Andrews. J. Amer. Chem. Soc., 1914, **36**, 2089—2091.

A silica (or porcelain) dish, with cover and short stirring rod, also preferably of silica, and containing 1·9—2·0 grms. of pure silver nitrate is heated to 160° C. and then to constant weight at 240° C. (or to incipient fusion of the nitrate). 50 c.c. of the hydrochloric acid (if $0{\cdot}2N$) are introduced, and the mixture is stirred to complete the reaction, evaporated at 95°—100° C., dried by heating as before, and weighed. A similar dish containing a like volume of acid, but no silver nitrate, is treated at the same time in a precisely similar manner throughout. The normality of the solution is then

$$\frac{W - W_1 + w_1 - w}{0{\cdot}02655V},$$

in which V is the volume of solution and W, W_1, w, and w_1 are the respective weights of $AgNO_3$ + dish, $AgCl + AgNO_3$ + dish, companion dish, and companion dish after the experiment.—F. Sodn.

Iodine solutions; Titration of alkaline ——. A. Leclère. J. Pharm. Chim., 1914, **9**, 341—345.

The titration of iodine solutions with sodium thiosulphate gives very irregular results in presence of alkaline salts, particularly when using warm solutions. Correct results can, however, be obtained by titrating the alkaline iodine solution first with thiosulphate solution, then with sulphuric acid using methyl orange as indicator until neutral, and repeating the iodometric titration on a fresh quantity of solution after neutralising with the amount of acid found in the first titration.—T. C.

Copper and lead from tin and antimony; Use of hydrofluoric acid in the separation of —— by means of electric current. L. W. McCay. J. Amer. Chem. Soc., 1914, **36**, 2375—2381.

Dilute nitric acid to which a little hydrofluoric acid is added is an excellent solvent for antimony and tin and their alloys, and if the metals are present in the solution in the higher state of oxidation, they are not deposited by the electric current, so that copper or lead if also present may be separated electrolytically, the former as metal and the latter as dioxide, from the tin and antimony. Satisfactory results have been obtained in this way in the analysis of white metal, about 0·5 grm. being dissolved in 25—50 c.c. of dilute nitric acid (1 : 4) to which 5 c.c. of 48% hydrofluoric acid are added; the oxidation of the antimony is completed by addition of potassium bichromate solution. Deposits of lead peroxide are preferably dissolved in a mixture of dilute nitric acid and hydrogen peroxide, and the lead determined as sulphate. Copper can also be separated electrolytically from tungsten, and mercury and silver from tin and antimony, by using a dilute nitrohydrofluoric acid solution.—A. S.

Vanadium; Detection and determination of ——. H. Manz. Pharm. Zentralh., 1913, **54**, 1095. Chem.-Techn. Rep., 1914, **38**, 33.

The most delicate reaction of vanadium is the production of a red coloration insoluble in ether, by hydrogen peroxide in hydrochloric acid solution. Vanadic acid is determined by heating with potassium bromide and fuming hydrochloric acid, passing the bromine vapours into potassium iodide solution, and titrating the liberated iodine with sodium thiosulphate. $V_2O_5+2KBr+6HCl=2VOCl_2+Br_2+2KCl+3H_2O$. 1 c.c. of $N/10$ thiosulphate is equivalent to 0·0091 grm. of vanadic acid.—O. PATENTS.

Hydrometers. J. G. Lucas, London, and E. V. Smart, Ilford, Essex. Eng. Pat. 22,790, Oct. 9, 1913.

Errors due to the meniscus are avoided by providing a float, guided on the stem of the hydrometer and carrying an indicator whose position against the stem gives the specific gravity, or carrying a vertical scale which is read against a fixed mark on the hydrometer. The float consists of two celluloid tubes joined by end-plates so as to form a rectangular frame with a slotted base for guiding it on the stem. The hydrometer bulb is of disc form, and the stem is flattened in cross-section and small compared with the capacity of the bulb. The hydrometer is suitable for insertion between the plates of an accumulator.—A. T. L.

Thermo-element. E. Achenbach. Ger. Pat. 276,354, Feb. 14, 1913.

Boron silicide is used as electrode material for thermo-elements. It has the advantage of having an electrical conductivity twenty times as great as that of silicon, whilst in other respects it is equally good.—T. F. B.

XXIV.—MISCELLANEOUS ABSTRACTS.

Nitrogen: Crude —— (nitrogen+rare gases) in natural gaseous mixtures. C. Moureu and A. Lepape. Comptes rend., 1914, **158**, 839—842.

Analyses of the crude nitrogen fractions obtained from such natural sources as the firedamp of mines, or from thermal springs have indicated a remarkable similarity in both qualitative and quantitative composition, and the conclusion is drawn that the constituent gases, nitrogen, argon, xenon, krypton and helium, have a common origin dating back from the nebulous epoch. Such slight variations as have been observed are amply explained by the operation at a later date of such physical processes as occlusion, solution, and diffusion.—G. F. M.

Sulphur solutions and compounds; The blue colour of ——. P. P. v. Weimarn. Chem.-Zeit., 1914, **38**, 482.

The blue colour of sulphur in solution in potassium thiocyanate or glycerin is a function of its dissolved state and is not due to the formation of oxy-compounds or to existence in the colloidal state. The colour of the solutions deepens on heating. The rose colour of ultramarine is explained by the sulphur being in solution in the form of its red vapour.—J. B.

Calcite which becomes phosphorescent when heated. F. Pisani. Comptes rend., 1914, **158**, 1121—1123.

A specimen of calcite, consisting of yellow and colourless crystals, exhibited distinct fluorescence when heated to about 150 C. The mineral was free from iron; the yellow crystals contained MnO, 0·06 to 0·07%, and oxides of the ceria and yttria group, 0·008 to 0·12%; the colourless crystals contained MnO, 0·15% and oxides of the ceria and yttria group, 0·005%. Both the coloured and the colourless crystals showed phosphorescence and the phenomenon does not appear to be due to the cerium-yttrium content since it is noticed in calcite free from rare earths. Fluorescent calcite is of rare occurrence; of numerous specimens from various sources examined, only three were decidedly phosphorescent, namely, calcite from Mayenne (France), Harz (Germany), and Derbyshire (England).—W. P. S.

Urease-content of certain Indian seeds. H. E. Annett. Biochem. J., 1914, **8**, 449—452. (See also Takeuchi, this J., 1910, 36; 1911, 566; Zemplen, this J., 1912, 597, 891; Armstrong and Horton, this J., 1912, 598; Falk, this J., 1913, 384.)

Out of six varieties of soya beans tested, the urease activity of five, viz., yellow, common, chocolate, black and Rymbsa Ktang, was practically identical, but that of the sixth, spotted soya bean, was distinctly greater. Urease appeared also to be present in the following seeds:—*Sida spinosa*, gram (*Cicer arietinum*), rice (*Oryza sativa*), cowa (*Setaria italica*), two samples of sword bean (*Canavalia ensiformis*) one from America, and the other grown at Dacca in India, *Urana lobata*, khulti kalai (*Dolichos biflora*), and castor bean (*Ricinus communis*). The urease activity of both the samples of sword bean was many times greater than that of any of the soya beans examined. Extremely rapid production of ammonium carbonate took place immediately on adding sword bean extract to urea solution.—J. H. L.

Glucosides, tannins, etc.; Action of —— on germination. W. Sigmund. Biochem. Zeits., **62**, 339.

Arbutin has but little harmful action on germinating seeds: of its components hydroquinone (quinol) is much more poisonous, whilst dextrose has no effect. Phloridzin, hesperidin, hesperetin, and phloretin have but little effect. Baptisin is a strong poison. Salicin is slightly toxic in a solution of 0·02 molecular weight in one litre. Helicin is more harmful. Populin, as far as it is soluble, has no effect. Coniferin is also but slightly active, but its hydrolysis products are more poisonous. Syringin and amygdalin have little effect. Aesculin is markedly toxic. Sinigrin and convallarin are not harmful. Helleborein is rather poisonous in relatively large doses, so are digitalin, saponin, and sapogenin. Strophanthin is poisonous. Phenol is toxic in a concentration of 0·02 molecular weight per litre. Pyrocatechol, pyrogallol, and resorcinol are very poisonous. Quinone in a concentration of 0·02 molecule per litre is fatal. Results are also given with saligenin, salicylaldehyde, benzaldehyde, vanillin, piperonal; salicylic, cinnamic, orthocoumaric acids; aesculetin, daphnetin; mandelic, protocatechuic, gallic, catechutannic acids; tannin and catechin.

Patent.

Tobacco; Process of treating [ageing] ——. L. W. Lawrence and F. F. Bahnson, Winston-Salem, N.C. U.S. Pat. 1,113,902, Oct. 13, 1914; date of appl., Aug. 28, 1914.

Tobacco is subjected alternately to the action of moist and dry air until properly aged.—W. P. S.

Trade Report.

Patents, Designs, and Trade Marks (Temporary Rules) Acts, 1914. Illus. Off. J., Nov. 18, 1914.

It is announced that the general principles upon which the Board of Trade will act in dealing with applications for the avoidance or suspension of Patents and Trade Marks under the above Acts, will be as follows:—

Patents.—Licences will, as a general rule, be granted where the applicants fulfil the necessary conditions, set out in Rule 1 of the Temporary Rules:—(1) Where there is no manufacture in this country under the Patent, and also (2) Where what manufacture there is, is carried on by a company or firm on behalf of alien enemies resident abroad, and there is any reason to doubt that the manufacture will continue to be carried on, or where it is in the interests of the country that some other manufacture should be started in British interests.

Trade Marks.—Suspension will, as a general rule, only be granted in the following cases:—(1) Where the Trade Mark is the name of a patented article, and a licence is granted under the Patent protecting it. (2) Where it is the only name or only practicable name of an article manufactured under an expired Patent. (3) Where it is the name or only practicable name of an article manufactured in accordance with a known process or a formula which has been published and is well known in the trade. Generally speaking, suspension will not be granted in the case of pictorial devices.

Prohibited exports. Revised and complete list.

A Proclamation dated November 10th, 1914, consolidates and supersedes all previous Proclamations or Orders of Council dealing with the same subject. In the main the list of articles is identical with that resulting from previous lists, with a few minor alterations. The full text is printed in the Board of Trade Journal of November 12th, 1914, pp. 414 seq.

Journal of the Society of Chemical Industry.

No. 23, Vol. XXXIII. DECEMBER 15, 1914. No. 23, Vol. XXXIII.

Official Notice.

DUTY-FREE ALCOHOL.

In view of the interest now associated with the conditions of supply of duty-free alcohol, the following statement has been prepared.

Duty-free alcohol in the form of methylated spirit is readily obtainable.

Mineralised methylated spirit.—To protect the immense revenue raised from potable spirit and to prevent misuse it is generally necessary to render duty-free alcohol non-potable. For common use this is effected by the addition of wood spirit (*i.e.*, crude methyl alcohol) and a trace of light petroleum, so that the mixture contains 10% of wood spirit and three-eighths of 1% of petroleum spirit. These small additions, whilst sufficient to deter most people from drinking the spirit, do not interfere with its use for a very large number of commercial purposes. Such spirit, which is known as mineralised methylated spirit, may be purchased throughout the country without formality in quantities not exceeding four gallons at a time from any retailer of methylated spirit, and permission to receive it in larger quantities is readily granted on application to the Commissioners of Customs and Excise when ordinary facilities for obtaining it are inadequate.

Industrial methylated spirit.—For manufacturers and large users of alcohol generally, however, and in those cases where a purer spirit is necessary, further provision is made by what is known as "Industrial Alcohol." This alcohol is denatured by the addition of half the quantity of crude methyl alcohol or wood spirit which is used in the mineralised methylated spirit, and no petroleum spirit is used; *i.e.*, this spirit contains 5% of wood spirit without other addition. Permission to receive this spirit must, however, be obtained and the use to which it is put be specifically authorised by the Board of Customs and Excise. Applications for such authorisation should in the first instance be made through the Surveyor of Customs and Excise for the district in which the spirit is to be employed. It should be noted that during 1913 the price of British industrial methylated spirit was lower than the price of alcohol in Germany.

Finally, in those cases where denaturing with wood spirit is proved to the satisfaction of the Commissioners of Customs and Excise to render the spirit unsuitable or detrimental for use in any art or manufacture, the Commissioners have power to grant the use of duty-free spirit under other conditions as explained in the following memorandum. Applications referring to this spirit should also be addressed to the Commissioners through the local Surveyor of Customs and Excise.

Pure spirit.—The following is the procedure to be observed in connection with the use in manufactures of pure spirit on which duty has not been paid (Sec. 8 of the Finance Act, 1902).

1. Any person desiring to use spirits without payment of duty in any manufacture carried on by him must make application in writing to the Commissioners of Customs and Excise for authority to receive and use such spirits, and must prove to the satisfaction of the Commissioners that the use of methylated spirits would be unsuitable or detrimental.

2. The applicant must give full particulars of the situation of the premises upon which and the purpose for which the spirits are to be used, together with a description of the process of manufacture. He must also state the means by which it is proposed to make the spirits unpotable before and during use, and the quantity likely to be required in the course of a year.

3. Any person authorised to receive spirits on which duty has not been paid must, if so required by the Commissioners of Customs and Excise, provide upon his premises a warehouse, structurally secure to their satisfaction, and all such spirits received must be deposited and retained therein until delivered on proper notice to, and in the presence of, the officer. He must also, if so required, provide a room approved by the Commissioners in which be fixed a vat or other vessel of sufficient size to admit of at least one hundred bulk gallons of spirit being rendered unpotable at one time, and must also provide satisfactory accommodation for the Officer of Customs and Excise in attendance at his premises. No charge is usually made for the services of this officer.

4. Security to the satisfaction of the Commissioners of Customs and Excise must be given for the due removal, safe custody, and proper use of the spirits, and the due observance of all regulations and conditions made by the Commissioners.

5. The substance or materials to be used for the purpose of rendering spirits unpotable and the mode in which the spirits are to be rendered unpotable must be approved by the Commissioners of Customs and Excise, and the person authorised to receive spirits upon which duty has not been paid must, if so required by the Commissioners, provide a store to be approved by them, and used solely for storing and keeping the substance or material so approved.

6. Spirits which have been rendered unpotable under these regulations shall not thereafter be purified in any manner or be recovered by distillation or any other means, except with the express sanction of the Commissioners of Customs and Excise.

The use of *absolute alcohol* is covered by the above regulations as to "Pure spirit."

Attention is also directed to the Report of the Departmental Committee on Industrial Alcohol (see this Journal, 1905, pp. 397—426), and also to the Minutes of Evidence taken before that Committee (No. Cd. 2477, price 2s. 4d.).

Birmingham Section.

Meeting held at Birmingham University, on Thursday, November 5th, 1914.

MR. H. T. PINNOCK IN THE CHAIR.

THE ESTIMATION OF MOISTURE IN ZINC ASHES.

BY ERNEST A. LEWIS.

The ferrocyanide assay of zinc is largely used in technical work and is accurate when carried out under standard conditions, but sometimes differences of 2% or more are obtained by assayers working on the same sample which has been passed through a 30 mesh sieve. The samples are prepared by grinding the ashes whilst hot, in which case the metallic zinc easily rubs up to a fine powder. The oxidation being negligible, this method is largely used by English smelters, and is to be preferred to the method of separating the fines and metallics by pounding and stating the percentage of each on the packets.

If the samples whilst hot are placed in bottles and sealed with sealing wax all over the top to exclude all moisture, there is seldom any serious discrepancy between assayers. It is evident that the errors must be due to the absorption of moisture which is not driven off by heating to 100° C., as is the practice of many assayers. In order to see to what extent zinc ashes of various types would absorb moisture, the following experiments were made. The material, which had been passed through a

30 sieve, was heated with continual stirring in an iron ladle for some minutes, as hot as possible without melting the zinc, put into corked bottles and allowed to cool in a desiccator. These conditions of heating are the same as many smelters use to estimate moisture. The samples were weighed out between watch glasses and then allowed to remain in the open air protected from dust for some days and re-weighed from time to time. A galvanizer's ashes containing about 3% chlorine gained 4·15% by weight in 24 hours, 4·66% in 48 hours, and 4·82 % in 72 hours. A sample of re-melted ashes free from chlorine gained ·57% in weight after 24 hours, 0·72% in 48 hours, and 0·76% in 72 hours. Some of the previous samples were left for some days in an artificially damp atmosphere; the material, which became caked together, was ground up in a porcelain mortar and transferred to a stoppered bottle. About 10 grms. was weighed out between watch glasses and put into a steam oven, and later to a hot air oven, remaining in each oven until the weights were practically constant. A sample of ashes containing about 75% Zn lost 1·87% after 4 hours in a steam oven, and a further 4·14% after 4 hours at 200° C., a total of 6·01%. The loss to the seller from being dried at 100° C. instead of 200° C. is thus equal to about 2·9% zinc.

Loss in weight per 100 *parts.* In another case, after 4 hours in the steam oven, the loss in weight was 0·88%, and after a further 4 hours at 200° C., 0·62%; total loss 1·5%. The loss in this case is equal to 0·4 unit of zinc.

The experiments were repeated with two other kinds of remelted ashes, free from chlorine. One sample gained 0·53 % on exposure to air for 24 hours; and 0·75% for 192 hours; when heated in the steam oven the loss amounted to 0·57%, whilst a further 0·31% loss occurred at 200° C. Another sample gained 0·30% during 24 hours exposure, and 0·52% in 192 hours; the loss in the steam oven in 4 hours was 0·25% and at 200° C. in 5 hours 0·32%. A sample of zinc oxide containing about 0·2% Cl gained 0·80% in weight on exposure to air for 24 hours and 0·84% after 72 hours; on heating for 4 hours in the steam oven the loss was 0·43%, and after a further 4 hours at 200° C., 0·46%, or a total of 0·89%.

Prolonging the heating much over 4 hours at 200° C. led to an increase in weight, due no doubt to oxidation of the metallic zinc.

These experiments show that it is not possible to remove all water from zinc ashes by heating to 100° C., especially when chlorides are present. Drying the sample at 200° C. for four hours practically removes all the moisture in all kinds of zinc ashes

Discussion.

The Chairman said the subject was of importance and might be given a much wider application, for there were difficulties in making such estimations in organic substances.

Mr. Alcock pointed out that difficulty was experienced in determining the amount of moisture in many substances, particularly in volatile oil and drugs. It must not be assumed that loss was always moisture; it might also be compensated by oxidation.

Mr. W. Clifford asked Mr. Lewis if he had any experience of drying the oxide, on the large scale. Was the moisture more easily driven off when chloride was absent than when present? It was not easy to get the moisture in the crude (galvaniser's) oxide below 50% by mere drainage and evaporation, especially if it contained a small amount of chloride. Was there a colloidal form of oxide which retained the moisture more tenaciously?

Mr. O'Shaughnessy pointed out that in the estimation of moisture, or what was called moisture, one was always faced with the difficulty referred to by Mr. Alcock; but in many cases in which such estimations were required not for scientific work, but for practical and control work, the difficulty might be overcome by the adoption of an arbitrary method, viz., drying at a fixed temperature under known conditions. After practical experience it was possible to interpret the values obtained very accurately.

Mr. Lewis said that to most smelters the word "moisture" meant everything volatile. The moisture was determined in order to get the dry weight of the whole bulk, and such residues were sold on the zinc content of the dry material. Some assayers adhered to the old method of drying at 100° C., and while a specially made steam oven might give that temperature, the average steam oven did not. He had had no experience of drying oxide in bulk. The moisture in the oxide was not as a rule much more than ½%, but he did not know how the makers got the amount down.

THE ESTIMATION OF NAPHTHALENE IN SPENT OXIDE.

BY WILLIAM C. DAVIS, B.SC. (LOND.), F.I.C.

The ordinary spent oxide from gas works contains very little if any naphthalene; the sample, however, which is the subject of this examination had been used in the Williams process for the extraction of cyanogen from the gas and contained a considerable quantity of naphthalene. It must, therefore, be assumed that the Williams process has in this case purified the gas, not only from cyanogen, but also from naphthalene.

The naphthalene is usually determined by means of picric acid as described by Colman and Smith (this J., 1900, 19, 128), Kuster (Ber., 1894, 1101) and Dickenson Gair (this J., 1905, 1279; 1907, 1263). These methods deal with the estimation of the naphthalene in coal gas, but Dickenson Gair gives a method for the estimation in spent oxide by dissolving out the naphthalene with alcohol and precipitating the clear solution with picric acid; no details are given.

A method for the estimation of naphthalene in tar is described in Lunge's Technical Methods of Chemical Analysis, vol. ii. p. 803; this method, which is proposed by White and Ball (J. Gas Lighting, 1904, **88**, 262), consists in weighing about 1 grm. of tar into a 50 c.c. Erlenmeyer flask provided with an air inlet and connected to a U tube. The first two-thirds of this tube is filled with quicklime and the remaining space with glass wool and phosphorus pentoxide. The entire apparatus is heated in an air-bath at 70°—80°. The outlet of the U tube is connected outside the air bath with a weighed second U tube immersed in ice-water. A current of air is drawn through the apparatus at a velocity of 2 litres per hour, which causes the naphthalene to volatilise and deposit in the cooled U tube. The operation is continued until the second U tube no longer shows an increase in weight.

For separation of the naphthalene from spent oxide the method of White and Ball modified as described below and also distillation with steam have been employed, and this latter method has proved more satisfactory.

Separation of the naphthalene by a current of warm air.—When working with this method great difficulty was experienced in completely volatilising the naphthalene. Ten grms. of the spent oxide were weighed into a bottle fitted with inlet and outlet tubes, so that a current of air could be drawn through it. The air current was passed for two hours over the sample of spent oxide, then through 10% citric acid solution to retain any ammonia, and then through three wash bottles containing measured quantities of a saturated picric acid solution of known strength in which any volatilised naphthalene is collected. The bottle containing the sample and also that containing citric acid were kept at 100° in an air bath. The contents of the wash bottles containing picric acid were then mixed together in a tightly stoppered bottle, heated in the water bath until all the naphthalene picrate was dissolved, and then cooled, with occasional shaking. The solution was made up to known volume, the naphthalene picrate separated by filtration and the picric acid in the filtrate estimated by titration with $N/10$ sodium hydroxide, using lacmoid as indicator.

When a current of dry air was used to volatilise the naphthalene the quantity found after two hours' treatment was 1·35%, and with moist air 1·9%. In both cases an examination of the spent oxide after treatment showed visible crystals of naphthalene.

Separation of the naphthalene by steam distillation.—The naphthalene, as was expected, was very easily removed from the spent oxide by steam distillation, and a simple and easy method of estimation of all the naphthalene as picrate was devised. The naphthalene picrate obtained was examined in order to find out if any other hydrocarbons were distilling over and interfering with the estimation.

The details of the method were as follows:—Ten grms. of the sample of spent oxide are weighed into a Würtz flask and subjected to steam distillation. The steam and vapours of the distillate are passed through a second small Würtz flask heated to 100° C and containing 50 c.c. *N*, sulphuric or citric acid, then into a condenser, and finally into a receiver consisting of a wide-mouthed bottle. The whole apparatus is sealed by placing at the exit a wash-bottle containing 25 c.c. of a saturated picric acid solution. The distillation takes about 10 minutes. After this has taken place the water in the condenser is regulated so as to allow any naphthalene to melt and run into the receiver; as soon as this is the case the picric acid seal is washed into the receiver and a further 125 c.c. of picric acid solution added. The receiver is closed with a rubber bung and heated in the water bath until a clear solution is obtained. It is then cooled with occasional shaking and the excess of picric acid determined by titration with *N*/10 sodium hydroxide. The whole estimation takes about 1½ hrs. The following results were obtained on samples from the same lot of oxide:—3·06%, 3·88, 2·98, 2·80, 3·16, 2·79, 2·81% naphthalene.

It was decided to test the method in two ways—by examining the naphthalene picrate for purity and by estimating known weights of naphthalene added to the oxide previously freed from naphthalene by steam distillation.

Examination of the naphthalene picrate for purity.—The naphthalene picrate obtained was subjected to steam distillation, and the naphthalene produced was dried by pressure between filter paper and the melting point determined. The residue of picric acid in the distilling flask was titrated with *N*/10 sodium hydroxide, and the amount obtained compared with that in the naphthalene picrate taken. The melting point of the naphthalene was only from 1°—3° below that of pure naphthalene, which melts at 79° C., so that there could only have been a very small quantity of other aromatic picrates present, if any The quantity of picric acid obtained from the naphthalene picrate was less by 25% than that estimated as having been combined with the naphthalene, as might be expected, since the naphthalene picrate is slightly soluble in the mother liquor and the water used for washing it.

Determinations with known quantities of naphthalene.—For the estimation of known quantities of naphthalene, it would have been best to make up a mixture similar in composition to the spent oxide containing known quantities of naphthalene, but this was considered almost impossible on account of the complexity of the mixture and the difficulty of getting a known quantity of naphthalene to diffuse uniformly through the mass. In order to work under similar conditions as far as possible, the check estimations were made by separating the naphthalene by steam distillation from 10 grms. of the oxide; when all the naphthalene had distilled the apparatus was allowed to cool and then a known quantity of naphthalene was added and estimated as described above. In the earlier stages of the investigation it was found that the formation of the naphthalene picrate takes place much more readily when the solid naphthalene in the distillate is crushed before heating with the picric acid solution, and again if the heating be carried out too quickly the naphthalene has a tendency to melt, and in this state it seems to react only very slowly with the picric acid. The method as carried out above appears to give results which are 10%—15% low. It was thought that a possible source of loss might occur in that the 150 c.c. picric acid solution are diluted by the distillate and by the water necessary to wash the tubes and the catch bottle into the reaction bottle. The volume of liquid obtained is usually 195 c.c.—205 c.c. at 33% dilution—the result being that some naphthalene picrate dissolves in the weak liquor. A series of tests was therefore carried out with weighed amounts of naphthalene in which, before heating the naphthalene with the picric acid solution, sufficient solid picric acid was added to make the whole solution saturated. The results obtained are given below:—

Weight of naphthalene taken.	% $C_{10}H_8$ taken.	Weight of naphthalene found.	% $C_{10}H_8$ found.	Error.
0·34 gms.	3·4%	0·306 gms.	3·06%	—10%
0·29 ,,	2·9%	0·302 ,,	3·02%	4%
0·31 ,,	3·1%	0·310 ,,	3·10%	Nil

A series of estimations was next made on the original spent oxide to compare the two methods, *i.e.*, with and without the addition of solid picric acid. In each case slightly higher results were obtained in those experiments in which the solid picric acid was used, the difference agreeing fairly well with the results previously obtained:—

No.	% $C_{10}H_8$ by original method.	% $C_{10}H_8$ by adding solid picric acid.	Difference.
1	—	2·92%	—
2	2·63%	2·77%	5·4%
3	2·57%	2·86%	10·1%
4	2·61%	2·91%	10·3%

Therefore when estimating naphthalene in samples of spent oxide or in similar cases in which the naphthalene can be separated in a state of sufficient purity by steam distillation a sufficiently accurate result will be obtained for most purposes if after the distillation, crystals of picric acid are added to the distillate in such a quantity that the resulting solution is saturated. but for a working test this is perhaps not necessary. It does not follow that in all samples of spent oxide the naphthalene can be estimated by this method unless the purity of the naphthalene picrate is tested as noted above.

As the sample of spent oxide which was the subject of the above examination has been shown to contain a higher percentage of naphthalene than is usually found in spent oxides it was examined as to its content of solid soluble in water, tar oils and sulphur. The following values were obtained: Soluble in water, 4·95% (ammonium thiocyanate, 71·45%; ammonium sulphate, 9·9%); tar oils, 1·78%; sulphur, 30·32%.

I wish to express my thanks to Mr. Rossiter for his advice during the preparation of this paper, and to the directors of the British Cyanides Co., Ltd., for permission to publish the results.

Discussion.

Dr. W. B. Davidson said that the author appeared to have achieved a satisfactory result, though there did not appear to be any great use in an estimation of that kind. In the Williams process there was occasionally some difficulty in extraction of cyanogen and the presence of naphthalene in the boxes containing spent oxide was no doubt due largely to the fact that liquor or water, sprayed in at intervals, had a condensing effect. The naphthalene was therefore collected gradually in the boxes, and it was certainly a nuisance in the process if the gas under treatment was pretty well laden with naphthalene. Ordinary spent oxide was very often acid. So much depended upon whether air was passed through the purifiers or not. In the Williams process the spent oxide was naturally alkaline because the liquor generally contained 4 to 6% of ammonia.

Mr. Pickering said he had tried washing the oxide with a warm solution of picric acid, practically saturated, finally washing the oxide with a little water and thus preventing loss, and then estimating the naphthalene in the picric acid. He checked the method by adding naphthalene to a sample of oxide which had been washed with picric acid; and he found his results to come to within 95% or 96% of agreement.

Mr. F. H. **Alcock** asked if Mr. Davis had found sulphuric acid with the naphthalene in the distillate? He would have thought it important to seek for other acids than picric. There might be present other things than naphthalene and picric acid. It might be advantageous to add a volatile agent to the spent oxide and then distil the naphthalene. Or the boiling point of the liquid containing the naphthalene might be raised by adding salt, shaking the distillate with ether, and then evaporating slowly. He did not agree that the detection in gas works spent oxide was of little importance, because if its vapour could be carried to the houses there would be a better illumination.

Dr. **Davidson** replied that the vapour of naphthalene would afford no advantage. The boiling point was 218° C. The vapour tension at ordinary temperatures was so low that the gas could not carry 0·008% by volume; and that was only equivalent to the light of a small fraction of a candle-power.

Mr. **Davis**, in reply, said he did not think washing of spent oxide with picric acid would be effective in samples from the Williams process, because ammonia was present. Further there would be a loss of naphthalene before the process was finished owing to time required for washing.

Manchester Section.

Meeting held at the Grand Hotel, on Friday, November 6th, 1914.

MR. JULIUS HÜBNER IN THE CHAIR.

THE OXIDATION OF SEWAGE WITHOUT THE AID OF FILTERS. PART II.

BY EDWARD ARDERN, M.SC., AND WILLIAM T. LOCKETT, M.SC.

In a paper[*] presented to this Section of the Society in April last, a long series of experiments were described dealing with the application of aeration methods to the purification of sewage. It was shown that the accumulated deposit designated "activated sludge" resulting from the complete oxidation by prolonged aeration of successive quantities of sewage, had the property of increasing enormously the purification effected by simple aeration of sewage. The research, which was confined to laboratory experiments, included an investigation of the conditions controlling the oxidising effect of the activated sludge.

The present communication is concerned with outdoor experiments on similar lines to those previously undertaken in the laboratory but on a larger scale. The whole of the earlier experiments were carried out on the "fill and draw" method. Working in this manner with Manchester sewage, it was shown that a highly satisfactory effluent could be produced when the sewage, in intimate contact with one-fourth of its volume of activated sludge, was aerated for a period of from six to nine hours.

Under the conditions of experiment, however, it was necessary to subject the activated sludge to a further period of aeration in order to maintain its highest activity.

It was suggested in the previous paper that improved results might reasonably follow the adoption of a continuous system of working. The following trials were therefore undertaken.

Continuous system experiments.—For the purpose of these experiments a wooden rectangular aeration tank of 35 gallons capacity was employed, measuring 4 feet by one foot, the depth varying from 21 inches at the inlet end to 12 inches at the outlet. The aeration was effected through a series of perforated pipes placed at intervals of 4 inches and fixed latitudinally at a depth of 12 inches from the surface. In order to ensure the complete admixture of the sludge and sewage, an additional perforated pipe was fixed at the inlet end along the centre of the base of the tank.

The effluent from the aeration tank passed forward to a sedimentation tank of similar dimensions, and means were provided for the removal of sludge from this tank with a minimum amount of disturbance.

The previous laboratory experiments worked on a "fill and draw" method, had shown that, in order to be certain of the complete nitrification of Manchester sewage, a period of from 10 to 18 hours aeration in contact with a certain proportion of activated sludge was necessary. Further, the maintenance of the activity of the sludge was apparently dependent on this complete nitrification. The first experiments on the continuous system were made with a rate of flow of sewage sufficient to fill the aeration tank in 24 hours, with the idea of ascertaining whether, under these conditions, a completely nitrified effluent could be maintained which would thus avoid the necessity for re-activation of the sludge removed from the sedimentation tank.

Examination of the effluents obtained by this manner of operation showed that such was not the case. The amount of ammonia present in the effluent increased as the experiment proceeded and eventually rendered it necessary to submit the sludge to a further period of aeration prior to re-circulation through the aeration tank.

As this further period of aeration of the sludge apparently could not be avoided, it was decided to increase the rate of flow of sewage so that a mean stay of six hours was obtained, a period which had previously been found sufficient to produce a satisfactory effluent when working on the "fill and draw" method. Working in this manner, it was of course necessary to make provision for the re-activation of the sludge employed. This was accomplished by introducing a separate aeration tank, in which the sludge received from the sedimentation tank was further aerated prior to passing forward to the aeration tank. Throughout the whole of this period the effluents obtained were non-putrefactive and contained varying amounts of nitrate, but the percentage purification effected did not compare with that obtained with a similar period of aeration when working on the "fill and draw" method. Moreover, there was a distinct increase in finely divided suspended matter and the effluents were imperfectly clarified.

Consideration of the possible reasons for this diminished purification, especially in view of the obvious mixing effect due to the admission of air, led to a study of the minimum period of stay in the tank of any portion of the incoming sewage. Such determinations made by replacing the sewage with a salt solution of known strength, showed that with a mean rate of flow of six hours, 3% of the incoming sewage would pass through the tank in less than twenty minutes, and 25% in under two hours. The decreased purification was thus largely accounted for, inasmuch as the sewage which passed through the tank with less than two hours aeration would retain in all probability, a proportion of its colloid matter.

It was thus apparent that satisfactory progress with this method of working was dependent on the design of a tank which without unreasonably increasing the mean rate of flow would allow a certain minimum period of aeration considerably beyond that given by the tank employed.

In the meantime, further experiments, to be described later, working on the "fill and draw" method had given such considerably improved effluents that the possible advantages of a continuous method of working were definitely minimised, especially in view of the fact that in these latter experiments the manipulation of the activated sludge is obviated. Attention was therefore concentrated on further experiments working on the "fill and draw" method. The authors do not consider the results of the above continuous experiments conclusive, and they hope at a later date to return to this question.

Outdoor experiments on the "fill and draw" method.—In all the previous work the aeration of the sewage was effected through plain tubes. During the progress of this investigation the authors had the advantage of noting the efficient distribution of air effected by means of porous tiles which were being used experimentarlly by Dr. Fowler and Mr. Mumford in connection with further work on the clarification of sewage by means of a specific organism. A similar method of air distribution was therefore employed in the following experiments.

---

[*] This Journal, No. 10, Vol. XXXIII., pp. 523 to 539.

For these experiments wooden casks of 50 gallons capacity were employed. The aeration was effected by diffusing the air through a porous tile placed on the bottom of the cask. In general the volume of activated sludge was equal to one-fifth of the capacity of the cask, and consequently when in operation the casks were filled with 10 gallons of sludge and 40 gallons of crude sewage. Preliminary trials showed that an average period of six hours aeration was sufficient to produce effluents of remarkable purity, as will be seen from the following table of analytical results, nitrification in the majority of cases being entirely completed.

TABLE I.

Oxidation of Manchester sewage.

Results in parts per 100,000.

	Raw sewage.	Effluent after 6 hours' aeration.	Purification.
4 hours' oxygen absorption	10·90	1·10	90%
Free and saline ammonia ..	3·66	0·43	—
Albuminoid ammonia	1·12	0·085	92%
Nitrite } In terms	—	0·10	—
Nitrate } of NH_3	—	1·79	—
Absorption of dissolved oxygen 5 days at 65° Fah. Royal Commission test ..	—	1·09	—

Note.—Proportion of activated sludge to sewage 1 : 4. Temperature varied from 15° to 22° C.

Comparison of these results with those obtained when plain pipe aeration was employed, showed at once the beneficial effect of diffused air.

The following experiments relating to the rate of oxygenation of sewage by the use of (*a*) plain tubes, (*b*) porous tiles, offer a reasonable explanation of the improvement.

TABLE II.

Rate of oxygenation of raw sewage.

Results in parts per 100,000.

Time.	Excess of air used. Strong sewage.		Average amount of air used. Dilute sewage.		Minimum amount of air used Dilute sewage.

" 45 " "	·56	·64	·56	·76	·22	·66
" 60 " "	—	—	·57	·77	·09	·56
" 90 " "	·57	·63	·63	·79	—	—

In the light of our earlier investigations, it appeared likely from the high degree of nitrification obtained in these preliminary experiments, that the activity of the sludge would be maintained without intermediate aeration of the sludge alone. The two casks were therefore operated according to the following cycle :—(*a*) 6 hours aeration period, (*b*) 1½ hours settlement, (*c*) ½ hour discharge of effluent, and thus each cask received 3 fillings of crude sewage per day, and dealt with a total volume of 240 gallons per day.

As the experiment proceeded it was noted that nitrification of the weaker morning sewage was completed before the end of the six hour aeration period and subsequently the cycle was modified so that the morning sewage was aerated for a period of 4 hours only.

In Table III. are given the average results obtained over a considerable period.

TABLE III.

Oxidation of Manchester sewage.

Results in parts per 100,000.

	Raw sewage.	Effluent after 6 hours. aeration.	Purification.
4 hours oxygen absorption	10·22	0·86	92%
Free and saline ammonia ..	3·56	0·32	—
Albuminoid ammonia	1·03	0·08	92%
Nitrite } In terms of NH_3	—	0·06	—
Nitrate }	—	1·87	—
Absorption of dissolved oxygen 5 days at 65° Fah. (Royal Commission test)	—	0·80	—

Note.—Proportion of activated sludge to sewage 1 : 4. Temperature varied from 16° to 22° C.

In view of these excellent results the period of aeration was further reduced to 4 hours, the casks consequently received 4 fillings per day and dealt with a total of 320 gallons of crude sewage daily.

The results obtained when working in this manner are recorded in Table IV.

TABLE IV.

Oxidation of Manchester Sewage.

Results in parts per 100,000.

	Raw sewage.	Effluent after 4 hours' aeration.	Purification.
4 hours oxygen absorption	10·23	1·03	90%

Nitrite } In terms of NH_3	—	0·07	—
Nitrate }	—	1·60	—

Note.—Proportion of activated sludge to sewage varied from 1 : 4 to 1 : 3. Temperature 15°—20° C.

The percentage purification was only slightly affected by the reduction of the aeration period from six to four hours.

The effluents obtained throughout this series of experiments were extremely well clarified and in general were superior to those yielded by the best type of bacterial filters.

The outstanding feature of these results is the fact that by employing diffused air the necessity for intermediate aeration and consequent manipulation of sludge was entirely removed and at the same time much better effluents were obtained than those yielded by plain pipe aeration when working with a similar aeration period.

The effluents obtained in the earlier laboratory experiments, when working with a six hours plain pipe aeration period, were liable to absorb an undue proportion of dissolved oxygen, as compared with that absorbed from acid permanganate of potash. It is therefore highly satisfactory to note that in the series of outdoor experiments under observation, the dissolved oxygen absorption of the effluents was remarkably low. This low dissolved oxygen absorption being coincident with a very low free ammonia content, appears to support the theory previously advanced, that the stage to which nitrification has proceeded is not without influence on the amount of dissolved oxygen absorbed.

General remarks. The earlier experiments showed that the question of temperature influenced the oxidation process. The above results were obtained during the summer with entirely favourable temperatures. It is scarcely to be expected that such a high rate of nitrification would be maintained throughout the winter months without the necessity arising of increasing the temperature of the sewage a few degrees, by the use of warm air or by other means.

During the earlier experiments it was occasionally necessary to increase slightly the alkalinity of the sewage dealt with, in order that nitrification should proceed without hindrance. Throughout the present out-door experiments, when working with 20 to 25% by volume of activated sludge no difficulty has arisen in this respect. The alkalinity or basicity of the sewage and sludge has always been sufficient to allow complete nitrification.

The opinion expressed on a previous occasion in regard to the possible retarding effect of abnormal quantities of bacterially inhibitory trade effluents, such as may be present, from time to time, in Manchester sewage, has been confirmed by wider experience in regard to the working of this oxidation process. As an example of this action, it may be mentioned that on September 6th a sample of sewage was dealt with, the 4 hours oxygen absorption of which was as high as 38·4 parts per 100,000, as compared with the usual average of from 8 to 13 parts per 100,000. This high oxygen absorption figure was caused by an undue proportion of tar compounds.

The effect of four hours aeration of this sewage in contact with the usual proportion of activated sludge was to produce an effluent whose oxygen absorption was 3·1 parts per 100,000, showing a purification of 92% on the original sewage. As might be expected, however, this abnormal sample of sewage exerted subsequently a deleterious effect on the activity of the sludge, more particularly in regard to the nitrification change. By increasing the aeration period to six hours over a period of a week, the sludge practically regained its original activity. In another instance more difficulty was experienced in re-establishing active nitrification.

Experience with this method of sewage purification has clearly indicated the necessity for adequate scientific control in order that the oxidation process may be maintained at its highest efficiency. The complete success of the process is dependent upon the maintenance of the activity of the nitrifying organisms, which, unless thoroughly established, are very susceptible to adverse conditions.

The difficulties previously mentioned concerning the maintenance of the activity of the sludge should not arise when dealing with domestic sewage, but where Manchester sewage or a strong trade sewage of similar character is concerned, it is obvious that careful attention will have to be paid to the varying nature of the sewage treated, with special reference to the presence of abnormal quantities of inhibitory trade effluents.

On the average, the amount of air used in the cask experiments described previously, has not exceeded 15 cubic feet of free air per square foot of tank area per hour. Special attention is being devoted to the question of the minimum air supply essential to the proper working of the oxidation process.

The important question of accelerating the rate of initial accumularion of activated sludge is also being closely investigated. Slurry obtained from percolating filters has been found useful in this respect. Experiments are also in progress to determine the most economical proportion of sludge to be employed.

The outdoor experiments described in this communication, are at present being translated on to the working scale by the use of a tank of 20,000 gallons capacity. on the basis of the cask experiments, it should eventually be possible to deal with 60,000 gallons of sewage per day in this tank, the area of which is 400 square feet.

For the present the authors do not propose to refer to the question of cost other than to say that the results which have been described shew such a marked advance on those hitherto obtained, as to add great force to the remarks made in the previous paper, in regard to the practical application of this method of sewage purification.

In conclusion, the authors have again to express their sincere thanks to Dr. Fowler for his continued interest in this research, and they wish to place on record their appreciation of his invaluable enthusiasm in regard to the progress of the experimental work.

The authors' thanks are also due to the Worshipful Company of Grocers for facilitating the progress of this research, by the election of one of them to a Research Scholarship.

They are indebted to the Rivers Committee of the Manchester Corporation, for permission to publish these further results of their investigations, which have been carried out at the Corporation Sewage Works, Davyhulme.

THE PURIFICATION OF SALFORD SEWAGE ALONG THE LINES OF THE MANCHESTER EXPERIMENTS.

BY S. E. MELLING, F.I.C.

Prior to the reading of the paper on the oxidation of sewage without the aid of filters by Ardern and Lockett (see this J., 1914, **33**, 523), I had, through the courtesy of Dr. Fowler, seen certain work carried out at Davyhulme upon raw sewage with activated sewage-sludge, under laboratory conditions.

At that time, these gentlemen, having already built up a reserve of the activated sludge to establish finally the principles of its action upon sewage under aerobic conditions—details of which were embodied in their paper and have been subsequently elaborated—were considering ways and means of translating the experiments on to a much larger scale.

As an official closely concerned with the problem of sewage disposal in the neighbouring Borough of Salford, it appeared to me very desirable to make some out-of-doors investigation along similar lines, particularly since we were fortunately situated in regard to the requisite air supply for extensive experiments.

Whatever measure of success has been met with in so far as clarification and purification are concerned, it must be made very clear at the outset that the all-important question of cost has not yet been shown. The results which have so far been obtained are such as to warrant an extension of the work, and we look forward with confidence to the time when this method shall reveal itself as altogether rational for the treatment of sewage.

A few words are necessary here in explanation of the plant which the Rivers Committee of the Salford Corporation placed at the disposal of Mr. W. H. Duckworth, the Manager of the works, and myself for the work.

The method of treatment at Salford is chemical precipitation of the screened sewage (lime and iron salts) and sedimentation followed by filtration. Interposed between the precipitation-tanks and percolating filters, is a system of so-called "roughing" filters, which were introduced by the late Mr. Joseph Corbett, Borough Engineer, some seven years ago. These roughers (six in number) form two of the original twelve precipitation-tanks, and cover an area of about 2000 square yards. They contain 2 ft. 6 in. of fine gravel, and their function is to intercept solids in the tank effluent, and so minimise the tendency to choke the percolating filters. During normal working, mechanical cleansing of the gravel-media by means of air, covers a period of about 18 out of the 24 hours. Below the media the air pipes are arranged crosswise; the air-outlets or jets are ⅛ in. diameter, and placed 8 ins. apart on the top and sides of the pipe; to each filter there are about 15,000 jets. A roughing filter is sub-divided into 3 sections, separated by dwarf walls 4 ft. 6 ins. high—a full section to within an inch or two of the wall-coping holding roughly 25,000 gallons.

Half of one of the above sections of a roughing filter, with a capacity of 12,000 gallons was exposed, and the floor so prepared as to obviate any appreciable settling out of the sludge during either the blowing or the quiescent periods.

On June 16th the first charge of crude sewage was introduced and air forced through at a pressure of about 2 lb. The procedure at first decided upon, was to continue aeration until such time as a diminution in reducing power, along with sensible nitrification, were observed, followed by settling for a sufficient period and careful decantation. At a later date, matters were accelerated by the addition of copperas at the rate of 16 grains per gallon (*i.e.*, on four occasions only); and also of washings from slurry (free from coarse detrital matter) which had been removed from the filtered effluent carrier.

The analytical results are embodied in the following tables:—

TABLE 1 (A).

Experiment commenced, June 16th, 1914. No chemicals added. Analysis of effluent on shaken sample. Temperature averaged 20·5° C.

Laboratory experiments upon Salford sewage, involving the gradual building up of sludge of such a degree of activity as to bring about, in from two to three hours, upwards of 85% purification, together with a clarified and stable effluent, are not quoted here. Whilst fully substantiating parallel records at Davyhulme they are of secondary importance when compared with the subsequent trials on the larger scale at Salford.

The results fluctuate from day to day sometimes unaccountably, but it would appear that the maximum effect—if any virtue can be attached to it—is brought about in approximately 48 hours. Whilst a very material reduction in oxidisable matters and also some clarification is seen, it would appear that the cause is more physical than biochemical.

As shown in Table 1 (D), the period of blowing was now

cut down, and the results are perhaps typical of what one might expect, in spite of any precipitation induced by the copperas added, since the amount of sludge at this stage is exceedingly small and its activity problematical.

Our next move was to accelerate the accumulation of sludge and to oxidise it as thoroughly as possible. Accordingly, on July 20th and 21st, the slurry washings from the filtered-effluent carrier above referred to, were added to the already-existing sludge, and blown, without a charge of sewage. The depths of washings, etc., was 14 ins. The blowing continued with little cessation until August 13th, by which time the physical character of the sludge had undergone certain changes, but most marked in regard to its flocculent condition.

On August 14th, fillings with crude sewage were recommenced and included in Table 2 are two series of interesting analyses :—

Table 2 (A).—In 24 hours there is 50% reduction in "free and saline" ammonia, 80% purification based upon the 4 hours oxygen-absorption test, and active nitrification is in evidence. At the end of the third day, there was very good clarification and the ureal ammonia is now reduced 88%, accompanying increased "nitrites and nitrates." By the fifth day, nitrification was practically complete, and the experiment was not carried further. The effluent gave a satisfactory result upon incubation at 36° C. for five days.

With the subsequent filling on August 21st, a not altogether unexpected difficulty was experienced. Occasionally Salford sewage is liable to contain highly-oxidisable effluents of an objectionable type—coal-tar oils, phenoloid bodies, and so forth.

It was almost too much to expect the sludge, which was showing signs of marked activity, would survive intimate contact with sewage of the type shown in Table 2 (B), but, although oxidation was quite incomplete in one day, the fact that nitrification was proceeding, in a very few hours, was highly satisfactory, Some inhibitory effect, particularly upon the nitrifying organisms present, was suggested by the result of the next few days, which were not so good.

From the 28th August to 6th September, a period is covered in which the blowing varied accordingly to circumstances: in one case it continued for 55 hours, but a full day was allowed as the minimum. Intermediate samples, however, were taken to trace the reactions proceeding, and without multiplying figures it may briefly be stated that the most drastic change had taken place by the end of the sixth hour. Reduction in "Free and saline" ammonia and "Albuminoid" ammonia in no case was less than 50%, and nitrification was well established. As regards clarification, comparison of the filtered sample with filtered tank effluent was consistently to the advantage of the former.

In the next stage (September 8th to October 16th exclusive) the effluent is sampled at more frequent periods, *i.e.*, after 1, 2, 3 and 12 hours. The average for 35 fillings is given in Table 3.

The purification is shown to be progressive as the sludge is gradually accumulating. When on the 16th October we were working with perhaps 20% by volume of the sludge, in two hours there was a purification of 91% based on the oxygen-absorption figure, and the "free and saline" ammonia had been reduced from 2·64 parts to 0·028 part per 100,000, with "nitrous and nitric nitrogen," 1·17 parts per 100,000. Beyond the third hour aeration gradually removes all the ureal ammonia, but clarification is not so good at the end of the twelfth hour than was noted at intermediate stages. As there is obviously no further supply of ammonia to be converted, increase in nitrification, as shown, probably proceeds at the expense of the activated material, and, as suggested by Messrs. Ardern and Lockett, this might account for the increased turbidity observed due to fermentation of nitrogenous matter in the sludge.

Materially reducing the full period of blowing to three hours, we now arrive at the latest stage of these trials, and the results both as to clarification and purification are so remarkable that I venture to give another table (Table 4), showing analyses up to the 30th ult. Having regard to the exigencies of the occasion we worked on October 18th at the rate of from 3 to 4 charges per diem, and are still proceeding along these lines. On the 23rd ult. we had more than sufficient activated sludge for our purpose, so that an additional section of approximately 22,000 gallons capacity was inoculated with about one quarter of the volume of the well-settled activated sludge from the first section. This extension of the work is giving very promising results. The characteristic physical property of the activated sludge has been referred to. Its average composition is shown in Table 5, and for comparison an analysis of ordinary "tank" sludge, as sent to see, is included.

There are many interesting points brought about by this investigation, but the main fact is established that it is possible to clarify and purify crude sewage in bulk in 3 hours, under the above-demonstrated conditions: in effect to produce an effluent that will more than satisfy any local or international standard.

In conclusion I have to acknowledge the generous advice given by Dr. Fowler, to whom I have referred many doubtful points on the subject. To my assistant at the sewage works, Mr. Norman Lovett, I am also indebted for the laborious care he has exercised throughout the period of these tests, and finally to Mr. Duckworth, the manager of the works, special thanks are due for his valuable co-operation and the painstaking control of the working conditions involved.

DISCUSSION.

Mr. J. P. Wakeford (City Engineer of Wakefield) said he had tested the process with the sewage at Wakefield, which was composed of various trade effluents, notably wool-scouring refuse, and partook of many of the characteristics of the Bradford sewage but was not quite so concentrated. Humus tank sludge was brought into condition by aeration, and the quantity gradually increased to 25% of the barrel capacity (35 galls.) by decanting off the top water and adding more sludge. By this method nine days were required for the experiment. Crude sewage was then added and aeration continued. In this way after 48 hours the free and the saline ammonia were completely removed; at the present time the same results were being obtained in something like three to four hours, which indicated that the sludge had become more thoroughly activated. The dry sludge contained organic matter 43·99%, mineral matter 56·01, nitrogen, free and saline, ·052; total nitrogen 4·59, phosphates 2·74, iron 9·67. The figure for mineral matters was accounted for by the fact that for some three weeks the crude sewage used was taken direct from the outfall sewer without any settlement. Of course it was advisable to give the sewage as effective detritus tank treatment as possible, but still the results were interesting. Money expended in the past on the construction of filters would not be money wasted, as the experiment showed the percentage purification was most rapid in the initial stages; therefore it would most probably be found cheaper to use aeration methods as a preliminary process rather than an end in itself. In practice it would be found that further aeration of the sludge was necessary to keep up its high potential energy. It would also be noticed that the iron figure of 9·67 was high. The iron had possibly acted as a catalyst in bringing down the colloidal matter, and if so it might be found advisable to add iron where it was not present in the crude sewage.

At the present time Wakefield sewage was costing about 17/– per million gallons for treatment with lime. He could not at present see why the application of air should cost more than about 10/– per million gallons.

Mr. Duckworth said that the quantity of sewage purified at the present time at the Salford works by the activated sludge method was about 80,000 gallons per day, with three fillings in 21 hours, on the fill-and draw system, with three-quarters of an hour to fill, three hours blowing, two hours settlement, and one hour to run off. A sample taken after blowing one hour was allowed to settle and was quite clear. The experiment appeared to be worthy of very full investigation on a large scale. It was intended in Salford to put a 12,000 gallon tank on a continuous flow. One difficulty had already shown itself, namely, the stopping up to some extent of the holes in the aeration pipes.

Councillor Mather said that the experiment conducted at Salford had been very encouraging. It was hoped that in a very short time there would be such a number of filters in operation as would enable experiments to be conducted on a very large scale.

Mr. **Welch** approached the question from the point of view of the engineer, who was perhaps not so optimistic about it as the chemist. The effluents produced and the manner in which clarification was obtained within such a short time were noteworthy. The great difficulty in sewage treatment was that as a rule it was impossible to obtain sufficient clarification. Tank effluent frequently contained a large amount of solid matter, and engineers had been compelled to add one series of filters after another. That solid matter appeared to a very large extent to be absent from the samples of effluent that Mr. Ardern had previously exhibited. Another remarkable point was that the sludge samples did not possess anything like the greasy, fatty appearance that was customary. He was surprised, upon an inspection of Mr. Melling's analysis of sewage sludge, to find that the fatty acids were 2·93 for activated sludge as against 5·0 for tank sludge, and the unsaponifiable matter 1·87 against 2·20. The sludge seemed very granular. He would have thought that there would have been less fat than appeared to be shown on the tables. From the original paper in April he gathered that the air pressure was used partly to blow the activated granular sludge so that it came into close contact with the whole of the sludge, and that it was this intimate contact between sludge and sewage that was responsible, to a certain extent at least, for the success of the purification. If that were so that might occur in the case of perforated pipes; but in the case of diffused air he would have thought the effect was somewhat modified. It might be possible to reduce that cost of the process by aerating for one hour to get about 90% of purification, and get a further purification by precipitation or filtration. Although the aeration process necessitated a certain amount of working expenses, it could certainly be balanced by an enormous reduction in the first cost as Mr. Ardern suggested, and his experience was borne out by later speakers, that tank accommodation for one quarter of the daliy flow would be sufficient to give a satisfactory effluent without further treatment. That suggestion appeared incredible. He suggested that it might be desirable to compare summer treatment and winter treatment by using tanks surrounded and covered with non-conducting material.

Dr. G. J. **Fowler** said the achievement of Mr. Melling in dealing with 80,000 gallons of sewage per day, with a purification of something like 90%, was worthy of great praise. An arrangement had been made by the Manchester Corporation to deal with the sewage of the Stockport authority, or a population of 100,000 at the Davyhulme works. In the ordinary way this would seem a rather large undertaking, but if Mr. Ardern's results could be substantiated on a large scale, and the experience of Salford showed that they could, the whole of the sewage of Stockport could be dealt with in a single tank at Davyhulme, and with a considerably better result than was being obtained at the present time with full double-contact, and moreover with the production of a sludge which contained three or four times as much nitrogen as ordinary sludge. The resulting sludge could be dried almost instantaneously and in appearance was almost like sand. It contained a large proportion of phosphates. He quoted a paragraph from a paper sent to the International Congress at Washington several years ago.

"The scientific solution of the sewage problem will not be attained until the following results can be guaranteed for any given case :—

"(1) An effluent which will not deteriorate the stream into which it flows.

"(2) No nuisance in the course of sludge disposal.

"(3) No nuisance from smell or from flies in connection with filter beds.

"(4) An expenditure strictly proportionate to the sanitary and æsthetic results achieved."

Apparently all four conditions were now capable of fulfilment. It was quite obvious that the expenditure could not be excessive in making provision for the blowing of a quarter of a cubic foot of air per minute per square foot of water surface for a period of three or four hours, because in the one process the whole thing was complete; sludge treatment, purification and everything else, with the exception of course of simple manipulation. The process described in the papers was the only process existing which purified sewage thoroughly from beginning to end in one operation. To that extent it really constituted a revolution in sewage treatment. Heretofore chemists had always been accustomed to think of the necessity of first a tank, then a filter, and then the production of some intractable material known as sludge. The new process put an end to these conditions. He now felt that it was in the direction indicated by the papers that the final solution of the sewage problem was to be sought. A debt of gratitude was due to the chemists who had undertaken research work on the new lines, but of course the development of an idea could not be credited to any one worker. The idea which started these particular researches originated really at the Lawrence experimental station at Boston, Massachusetts. He was interested in Mr. Wakeford's statement concerning the probable catalytic effect of iron, and probably "M7" played some part in the process. A great amount of research work still remained to be done on the bacteriological and physico-chemical side of the question, but the further investigation was carried the easier the problem appeared to be.

Mr. J. H. **Lester** was struck by the extreme simplicity of the processes. There were many iron precipitation methods, metallic iron had been used in the "Electrical" process, and iron largely accounted for the purification taking place in contact beds, but probably the best method of distributing iron in colloid form was that now described, in which the iron was distributed throughout the sludge and was thoroughly mixed with the sewage.

Dr. J. **Grossmann** said that the question of cost was the principal factor. Again, if air was blown through a liquid there was bound to be a certain amount of spray. Would his tend to the creation of a nuisance in the case of sewage, and was it possible for pathogenic germs, which otherwise might be latent or stagnant, being blown about in the atmosphere? The treatment of sewage not only involved purification but also highly the important sludge problem.

The present process was understood to be biological, though he was not aware that that had been clearly demonstrated. It would be interesting to learn definitely whether it was or was not a purely physical process, or to a great extent a physical process, the result being simply due to the much larger surface which was given to the sludge. For instance, if fifty parts of sand, kieselguhr, or other substance were mixed with one part of sludge and air blown through it, would the same result be obtained? Mr. Melling's figures indicated that the sludge treated was abnormal, because the nitrogen content was low and so was the grease (sum of unsaponifiable matter and fatty matter). The mineral matter was reduced by blowing from 68·8 to 45·5%: the only conclusion he could draw was that there was an addition in bulk of 50% of sludge as the result of the process by blowing. The figure of 7·2% for total fats in a sludge was extremely low. It appeared to him that altogether a much larger bulk of sludge was formed, and he would like to learn whether exact observations had been made on the point. The activated sludge contained 94·6% of water and the ordinary tank sludge 88%; this in addition to the other increase in bulk shown by the decrease of the mineral matter would increase the bulk of the sludge produced by this method considerably more than threefold. And in dealing with the sludge subsequently more than twice the quantity of water would have to be removed by some means or other. Mr. Ardern had stated that a great deal of the water could be eliminated by a process of fine sieving so far as laboratory experiments went, but it was doubtful whether such a system could be applied on a large scale. Sludge containing 5% of fatty matter was unsuitable for agricultural purposes, so that it would have to be degreased in order to obtain a marketable product, and three times the bulk would have to be dealt with.

Mr. **Ball** said that if the figure for nitrogen could be maintained it might be possible to make a profit out of the sludge.

Mr. W. **Thomson** inquired whether the sludge had been examined for bacterial life, and whether there was an increased quantity in the activated sludge. The greater proportion of mineral matter contained in the ordinary as compared with the activated sludge might possibly be explained by the mineral matter falling to the bottom during aeration. The phosphoric acid in the activated was about twice the quantity of that in the ordinary sludge. Was it possible that that could have any effect upon the rapid development of bacterial life? Assuming phosphoric acid had some considerable effect in propagating bacterial organisms, would finely divided bone charcoal, when mixed with the sludge, increase the purifying action on the sewage? In sewage matter there was always a certain amount of protoxide of iron, the sewage matter having the effect of deoxidising the peroxide of iron. It was probable that the iron oxide present in the sludge might act as a catalytic agent in bringing about the more rapid oxidation of the organic matter.

Mr. Pettigrew asked whether the sludge was not extremely liable to putrescence. It appeared to him, from the sample he had seen, that after partial or wholly drying it was extremely liable to have a strong odour. In Glasgow, for the ordinary treatment of their sewage in the East End, they ran the sewage on to the old sludge, and in half an hour obtained a much superior effluent than they did when they worked the process continuously. He was very pleased to find that the idea which was originally stated, that the air was only to be used for mixing the sewage, had been dropped. He believed the rationale of the process was that it did away with the filtering media of a biological filter, and the ease with which the sludge or the humus matter coming from a sprinkler filter was rendered fit for activated sludge appeared to demonstrate that that was practically the basis on which the process operated. It was not necessary to have an oxygen saturated atmosphere in a filter; in fact, the result was rather deleterious. A small quantity of oxygen was necessary. Probably some of them had read Dr. Angus Smith's works, and they would remember his statement that when he blew air through sewage there was never putrescence; the sewage effluent had to be prevented from turning all the oxygen into carbonic acid. He was pleased to find it had been shown by Mr. Ardern's paper that the actual presence of free oxygen in the effluent was absolutely necessary, and also that it was requisite to pay attention to the method of distributing it. He thought the views of some of the gentlemen who had spoken would be modified if they saw the samples of effluent; when they saw how compact the sludge settled, how granular it was in appearance, and the clearness of the liquid obtained on the top. There was another question to be considered, and that was the small amount of nitrogen obtained after having got rid of the free ammonia and the nitrogen in the effluent. If all the nitrogens were added together there was very much less nitrogen contained in the effluent than there was in the original sewage. For instance, a biological filter might give a nitrogen content of about 2½ grains to the gallon or 1·5 on the average, whereas the effluents he had seen had a nitrate content of about 0·2 to 0·5. He should imagine if activated sludge was allowed to stand nitrogen gas would be given off.

Mr. Ardern, in reply, said they were naturally very pleased to hear of the success of the aeration experiments at Wakefield. He had rather anticipated that with sewage containing a high proportion of soapy matters, preliminary treatment with lime would have been required. In the light of the experience gained at Manchester, he was rather of opinion that it would be more economical to carry the oxidation process to complete oxidation in tanks alone, rather than to reduce the aeration period and nitrify the resultant effluent on filters working at a high rate. Working in the latter manner, there appeared to be considerable difficulty in maintaining complete activity of the sludge, as this was dependent on the stage to which nitrification proceeded. If, therefore, the question of intermediate aeration or reactivation of the sludge had to be considered, the difference between the cost of complete purification in tanks alone, and that necessary for clarification or partial purification, did not leave much margin for filtration charges. With regard to the Wakefield experiments it could not be assumed that the high percentage purification obtained with one hour's aeration would be maintained, if the sludge was called upon to deal with successive quantities of sewage with a period of one hour's aeration each. In regard to the method of air distribution, a contrivance in the nature of a box was employed, the top surface of which was composed of a specially prepared porous tile. The air was admitted underneath and diffused through the porous tile. It was highly important to obtain a complete admixture and intimate contract of the activated sludge with the sewage, otherwise not only was a proportion of the sludge removed from the sphere of action, but the deposit of sludge resulting from imperfect circulation, was liable to give rise to secondary changes inimical to the oxidation process. The covering of the tanks as suggested by Mr. Welch might be useful, but the winter temperature of many sewages frequently fell below the optimum required for the most efficient working of the process, a difficulty which could not be overcome by any methods designed purely from the point of view of the conservation of the heat of the original sewage. The question of cost had received serious consideration, and from this point of view the process was eminently practicable. The actual cost would depend on details concerned with the mechanical application of air, which remained to be fully developed. There was much to learn in regard to the mechanism of the reaction, whilst physical actions were undoubtedly involved, the purification process was essentially a vital one. The real activity of the sludge was considerably influenced by the stage to which nitrification proceeded. An experiment with sterile sludge quoted in the previous paper showed no purification effect. The possibility of nuisance or danger from the moist atmosphere rising from the surface of the aeration tanks, could only be regarded as infinitesimal when compared with the present-day methods of sewage purification. No reliable determination had yet been made of the volume of residual sludge resulting from the oxidation process. Since a sludge containing upwards of 4% nitrogen was looked upon rather as an asset than a liability this question had not been considered of vital importance. He could not agree that the low fatty matters content of the dried sludge would inhibit its use as a fertiliser. A large number of manures on the market contained a greater quantity of grease.

The sewage of many industrial towns contained appreciable quantities of iron, and the question of its action as a catalyst or conveyer of oxygen was one of considerable interest. This question was at present being investigated. In principle there was no difference between the reactives invoved in the aeration tank and in a percolating filter. In the aeration process the action was intensified by a more intimate contact with the sewage of a greater proportion of sludge in a more thoroughly oxidised state. The loss of nitrogen referred to by Mr. Pettigrew was more apparent than real because of the dilution effect of the volume of sludge employed, the free ammonia content of which would be practically nil.

However, there was usually a loss of nitrogen, which apparently varied directly with the rate at which the free ammonia was removed. Previous experiments had shown that quantitative nitrification could be obtained when working with a small proportion of sludge and a longer period of aeration, while as the quantity of sludge employed was increased and the aeration period required for complete purification consequently reduced, certain nitrogen losses were observed. The reason for this was at present undetermined.

Mr. Melling said that he had dealt with sludge similar to that taken out to sea by the S.S. "Salford" three or four times a week; the mineral matter was, in fact, higher in proportion than in normal Salford sludge. In the Salford experiments the bulk of sludge was found to be a rapidly-increasing quantity. When a change was made to charges of three hours' full aeration there was built up such a volume of activated material that a week later there was 33 to 35% by volume present. It was not necessary to carry the experiment beyond 25%. The excess over and above what was necessary was employed to inoculate a tank twice the size, and it was largely owing to the quick and highly satisfactory results obtained in the second tank that Mr. Duckworth had spoken with optimism as to the success of the treatment. In reply to Mr. Thomson, the samples of sludge were taken indiscriminately from different parts of the tank and at different depths, and all mixed together, and a representative sample taken from the bulk. It had not been possible to differentiate between what had been termed the "sandy" and the organic matters.

The problem of the conservation and utilisation of sludge containing such a high percentage of nitrogen would have to be seriously considered as almost apart from sewage purification; in his opinion, there were great future possibilities.

Meeting held at Bolbec Hall, on Wednesday, November 18, 1914.

PROF. H. LOUIS IN THE CHAIR.

GERMANY AND CHEMICAL INDUSTRY.

BY N. H. MARTIN.

Although I have had more than fifty years' experience of making chemicals, and of handling and examining a wide range of the chemicals which are made in this country and in Germany, the problem of the Chemical Industry of Germany is so complex and requires for its full understanding the consideration of so many factors that I can only hope to indicate some of the ways in which she has gained such supremacy as she enjoys. If it were not so regrettable, because it misleads the public and influences the legislature, it would simply be ridiculous to contemplate the astounding ignorance which prevails as to the part which England has played and the share which she still holds in the great edifice of Chemical Manufactures. Her supposed decadence is set down, even by members of our own Society, to want of enterprise, of scientific knowledge and of capital. In no other great industry for which England is famous is it so frequently stated that those who carry it on have allowed a competitor to gain innumerable advantages over them, by ignorance and indolence. If I can divert your minds from such loose talk and through you the minds of others, and concentrate attention on some of the true causes which have in so many ways handicapped English manufacturers I shall feel that I have done some small service to my country of which I am proud and to those who conduct chemical manufactures, of whom neither I nor any Englishman, who knows or will take the trouble to ascertain the facts, need be ashamed.

At the outset I must dissociate myself from the cry "War on German trade" which is so prominent a topic in our newspapers and in the mouths of public speakers. If as the result of this unhappy war the industrial and productive capacities of the German nation are crippled it will be an irreparable loss to the whole world. Whatever belongs to Germany as a consequence of her natural resources, of the genius and industry of her people, will I hope remain to her and go on increasing for generations after this war is over and its ravages have passed into history. I do want, however, to defend the products of the brains, the industry, and the honesty of Englishmen from the unfair attacks which are made upon them, and there is no reason why Germany should not be taught —and if need be compelled—to be as honest in manufacturing and distributing her productions as we hope she will be forced to be in her political relations.

For the present purpose I will roughly group my remarks under four heads, and then by way of illustration quote some facts and allude to some specific handicaps which are imposed upon us. The four heads are, labour, patents, registration of trade marks, and finance.

In the matter of *labour* and its price the Germans have decidedly gained the better of us in the past forty years. We had the most highly skilled and industrious workmen (I include brain as well as hand workers) the world has ever seen, and in the building up of England's wealth and reputation they were free to put forth their best efforts, but from causes which I need not explain a considerable number are now content to perform their duties in the most perfunctory manner. I suppose we all have in our minds the great aniline industry of which Germany has captured so large a proportion of the output and which has been the basis and the initiative of a large amount of research in respect to other departments of synthetic chemistry. While our makers were handicapped by many difficulties of which alcohol was a very important one at the time, the Germans were making large sums of money which enabled them to increase their staffs of scientific chemists and, in order to keep them employed, they filled up their time in making large series of chemicals only wanted in small quantities and considered not worth the attention of an English manufacturer. One great difference between the English chemical manufacturer and the German has been that the former concerned himself mainly with heavy chemicals and those which were required in large quantities while the German would make any and everything, however small the quantity, and he had an abundance of *cheap* scientific labour at his command. In another very important department connected with the success of chemical industry, namely, the making of glass and porcelain ware, graduated instruments and so forth, which were formerly made to a large extent in this country, it was not a case of the Germans capturing the trade but of our workmen driving it away by the despotic and arbitrary conditions which the workmen through their Unions imposed on themselves, and now the art of making such things is almost lost to this country and it will not be revived unless wiser counsels prevail.

Patents.—I am not competent to deal with the great question of our Patent laws and the various ways in which they have played into the hands of Germany or been twisted by Germans to their own advantage, but that this has been to them a source of very great wealth there is not the smallest doubt. I would recommend those who are interested to read the remarks under the head of "Reform of our Patent Laws" in the Presidential address which Mr. Levinstein gave at the Annual Meeting at Liverpool in 1902. For a long term of years the Germans were free to hold patents in this country and to send the product here for sale without employing a single labourer or contributing a fraction to the government or expenses of this country. This was intended to be remedied by the Patents Act of 1907, and to some extent it has probably been done, but even here, if rumour may be trusted, the proverbial coach and six is often driven through the Act and more or less of a pretence of manufacturing is set up while the bulk comes in from Germany. According to a decision of Lord Justice Parker the *onus probandi* that the patent is not being "adequately worked" is placed on the complainant, who has no access to the patentee's books or means of proof as to the ratio of manufacture to actual sales. In this connection I quote from a Patent Agent of wide experience who writes :—"The English Courts are so studiously fair that they are more disposed to lean towards a foreigner than against him." This Act, by the way, known as Lloyd George's Act is an example of protection pure and simple given to us by a free trade government.

Trade Marks.—In the use of trade marks the German has twisted the English law to suit his own purpose. Instead of using the registered trade mark as a brand to distinguish the goods of one manufacturer from similar goods made by another, they invariably used it as the name of the article itself, and having by various methods got this word adopted by the users they secured to themselves the monopoly of the whole manufacture of certain definite pharmaceutical preparations, such as antipyrin. They were not content with doing this in the case of things which they discovered and introduced, but they also applied it to scientific preparations which were discovered in this country, and thus diverted the trade in the article to themselves. As an instance of this I may mention an important derivative of morphine, diacetyl morphine hydrochloride, which was discovered in Great Britain and described in English scientific literature and was afterwards made by a German house who sold it under the registered name of Heroin.

Finance.—After giving our foreign competitors opportunities denied to Englishmen of accumulating riches, it is adding insult to injury to taunt the latter with the lack of capital to embark upon chemical manufacture on an adequate scale. But things are not always what they seem and their very wealth and the facility with which they get support from the State and help from their banks may have tempted the Germans to speculate beyond the region of prudence and even have led to their financial undoing. There is no lack of capital in this country which will quite easily and naturally flow into the channels of chemical manufacture when it is encouraged to do so. The suggestion for the creation of special banks to deal with this and, still more foolish, the suggestion that the State shall come to the aid of manufacturers with advances of capital, can only come from those who are conscious of their inherent incapacity to face this problem unaided. Men with brains and character and a reasonable initial capital can obtain privately from any English bank all the capital which the wise development of their enterprises may require.

Since this note on State Aid was written I see that the Government through the Board of Trade has decided under certain circumstances to subscribe a portion of the capital and to guarantee the interest on a considerable further proportion to enable the consumers of dyestuffs to form a company to manufacture dyes for their own use. Presumably there is nothing to prevent this new company from obtaining the monopoly of the manufacture as, if the new company is established, "the Government would be prepared to take all necessary steps to secure the acquisition of any other concerns in the United Kingdom whose transfer to the new company might be desirable." On behalf of manufacturers I view this step on the part of the Government with some misgiving. There is absolutely no more reason for the Government either directly or indirectly to subsidise or assume control of the dye manufacturing industry than of any other chemical industry. There are large and important aniline dye manufacturers in this country who will quickly cope with the necessities of the consumers, and as they have struggled for so long a period against the unfair handicap which the Government has allowed, it is unjust now to create a government factory, which may easily become a monopoly, to deprive them of their legitimate reward. If you want to know the part which England and Englishmen have taken in this great enterprise read the whole of the address by Mr. Levinstein to which I have before alluded.

At the outset I alluded to the ignorance which prevails as to what England does do in the way of manufacturing chemicals of prime importance, and nowhere is this more apparent than in the region of medical substances. With regard to morphia I am informed that even so able a man as Sir William Tilden in the "Times" bewailed that this "to a considerable extent" came from Germany, whereas as a matter of fact practically the whole supply for Europe, including Germany, is manufactured in Great Britain. Quinine is, of course, made on the Continent, but the production in this country is far more than is required for the whole of the British Empire. Caffeine was first made by an Edinburgh firm and exhibited by them at the Vienna Exhibition of 1873; after that, when the demand increased, it was made in Germany until our Government allowed the waste tea which came into the London Docks to be denatured, after which and ever since caffeine has been made to an enormous extent in this country.

Many other alkaloids are produced in this country in large quantities, and one maker to whom I wrote replied:—"On the general question of alkaloids we may assure you that in scarcely any instance have we ourselves been outstripped by Germany in such products as we have ever seriously taken up. On the contrary before the war Germany was our best customer and we venture to think this is a fairly good answer to a great deal of the loose talk at present indulged in by writers to the newspapers on what is sometimes described as the decadence of British industries."

With regard to chloroform, I am assured that practically none came from Germany, and also, while chloroform is made in Germany for their own consumption, that it is British chloroform which to a considerable extent is exported to all parts of the world.

With regard to synthetic drugs which figure largely in the popular imagination I cannot do better than quote the following from the address on education and competition which I delivered before this Section in 1899.

"Amongst synthetic remedies antipyrine was controlled by a German patent and was a great success, but its very success has proved a snare to German science. Hardly a month passes but that some new substitution compound with a trivial name to indicate its alleged medicinal properties, and a scientific name intended to suggest profound research, is introduced to English medicine. They come with laboratory and medical reports attested by men with University degrees, couched in language calculated to deceive the very elect, but the touchstone of practical trial reveals how science has been prostituted to commercial ends, and the substances, one after the other, pass into oblivion. Such experience serves to bring discredit upon chemical novelties introduced from Germany, and suggests the thought that when science ceases to pursue truth for its own sake, and becomes the badly-paid slave of commerce, its deterioration is inevitable."

This is as true to-day as when it was written, and although for a time we are placed at a great inconvenience with respect to the *few* remedies which are of value, I am assured by one of the oldest aniline manufacturers in this country that there are no difficulties in making these drugs by anyone who understands the business, that they are making them and are increasing their output enormously, and that probably other people will be making synthetic medicinal products.

With regard to scores of other medicinal synthetic remedies (so called) the sooner they are consigned to the oblivion from which German enterprise brought them forth the better for science and for medicine.

I will give you one other instance of a handicap if you will pardon a personal experience. It was Brown-Sequard, a Frenchman, who first made suggestions with regard to the medicinal value of certain internal secretions on which is based the whole fabric of modern scientific organotherapeutics and our own fellow-townsman, Prof. George Murray, who first put to practical use in medicine the most important of them all, thyroid extract, which my firm manufactured for his use. Although we were thus the first to manufacture animal extracts of the kind in this country, we were soon, in the case of one of these, outdistanced by the importation of the active principle adrenalin from America and then from Germany. The manufacture of this particular active principle was impossible without being able to gauge the activity and purity of the product by experiments upon animals and we were compelled to seek, and we obtained, the licence from the Government to do this, after which we were not many weeks before we were manufacturing a product which in all respects was equal to what was being made and sent into this country from abroad. There exists this difference in regard to experimental research in relation to medicine, at home and abroad, that while in Germany and America no difficulty is placed in the path of scientific research or manufacture, we at home are hampered by numerous restrictions and it is only with difficulty and at great expense that we can obtain suitable animals for our purpose. Hundreds of such derelict animals are annually destroyed in this town in what is called the lethal chamber, without having been of the smallest service to any human being, whereas in our and similar laboratories during their passage to euthanasia the same animals might have performed great service to suffering humanity and helped to redeem our investigators and manufacturers from the stigma of being without scientific knowledge or technical skill. In this instance a little group of well-meaning persons with badly balanced minds are able through the legislature to impose a definite handicap on such workers.

One other matter which will of necessity arise in connection with this subject is the question of fiscal safeguards. We cannot estimate how big a factor this has been in Germany's success—probably larger than all the others put together. Although on other grounds I have for thirty years been a tariff reformer, I should deprecate any panic or greedy legislation in the direction of protection, but I should be prepared to consider wise measures of defence so that any and every industry in this country, including the chemical industry, should receive fair treatment and be placed on a basis of equality in meeting its foreign competitors. England is the only country in the world which goes naked and unarmed into the world of production and expects to hold her own against unscrupulous competitors, and I throw out the suggestion that it may be worthy of consideration whether the competition of Germany or any other country should not be held in check by forbidding the importation into, and selling any products in Great Britain, and as far as possible in her colonies and dependencies, at a less price than they are sold in the country where they are produced.

In conclusion every member of our Society should be a missionary of truth to the outside world and do his share to dispel the mists of error which have grown round this subject, instead of allowing the uninstructed man in the street through his political tendencies to handicap and defeat the aims of the intelligent and patriotic few who, amidst unparalleled difficulties, have kept alive the torch of chemical research and manufacture in this country.

Discussion.

Professor P. P. Bedson said it had always appeared to him that Germany's position in chemical industry was very largely due to the educational facilities whereby scientific knowledge was diffused amongst the people, who in consequence were ready and willing to provide capital to carry on scientific chemical industries. In the manufacture of heavy chemicals, such as sulphuric acid by the contact process, and the ammonia soda process, the fundamental reactions were discovered in this country, but it was Germany who brought them to perfection as industrial processes. What was wanted in this country in connection with the chemical industries was the application of brains, and educated capital. It was of little use to have chemists doing good work capable of industrial application, unless they had educated capital to support it. One of the great advantages which Germany enjoyed in connection with the manufacture of aniline dyes and similar products was that she was able to employ scientific labour. Only a board of directors, fully conversant with scientific methods and knowledge, could have sanctioned the expenditure of the money (nearly a million sterling) on investigations which the manufacture of artificial indigo necessitated.

The last time he was in Germany he was much impressed in the works he visited by German thoroughness and the extensive scientific staff employed. In this country there was nothing like the same extensive scientific equipment. The nearest approach was Messrs. Brunner, Mond & Co., where they had a large and technically-equipped staff; this was doubtless due to the fact that the founders of the enterprise were men educated on those lines themselves, who understood and appreciated research; and until in this country this system was more widely extended, he did not think they could advance much in the manufacture of fine chemicals. The services of the chemist in works in this country were not appraised nor utilised as they ought to be. Not infrequently instances were met with of the baneful influence of engineers and engineering—chemical factories under the control of engineers who had no knowledge of chemistry, whereas the chemist himself occupied quite a subordinate position. He was not given the opportunity of expressing his opinion on purely chemical matters, or if at all, then only through a medium imperfectly acquainted with chemistry. That was not as it should be. In a chemical manufactory of any kind the chemist should have a recognised and responsible position. Until the science of chemistry received its due recognition in the works there could be little success attending its industrial application.

Dr. J. T. Dunn would have liked to hear more of the views of industrial and commercial men, who were more directly in touch with facts than he. Still, a professional man did see something of what went on, and perhaps saw tendencies of which the industrialist was not conscious. He said that even if free alcohol had been available in this country, and had our manufacturers been able at that time to set up works at once to make aniline dyes, it was doubtful whether they would have devoted any considerable portion of their profits to the establishment of research laboratories. He could not see why things such as filter paper and laboratory glass should not have been made quite well in England, unless it were that the English manufacturer's mind did not work in that way, and that with his tendency to let well alone, he refused to have anything to do with a process which would not at once be profitable. He instanced the by-product coke industry. Durham was the home of coke, and at the present time the old bee-hive oven was largely superseded and by-product coke ovens had risen in all directions; yet the home of the by-product coke oven was Germany, and he questioned very much whether at the present time we should have had any by-product coke ovens in England if there had not been by-product coke ovens in Germany. Our colliery owners and coke manufacturers seemed inclined just to go on making no doubt handsome profits from their minerals under the old conditions, but, on the other hand the German tackled the problem scientifically, and it was only through his initiative that the system was introduced into this country, when the Durham coke-maker found there was a danger of his being ousted from the markets by coke made in Germany from his own coal. We were also equally well able with Germany to build these ovens, but up to the present time a considerable portion of these ovens was built with purely German materials. This was one of the largest fire-brick districts in the country, then why were we not ready to produce proper fire-bricks for building these ovens? Largely, he thought, because fire-brick makers had certain clays which their fathers had used and they made fire-bricks from them still in the same way. They did not consider the subject from the scientific point of view. If a fire-brick did not answer to certain purposes they replied that "it was a pity," whereas the German tackled the problem scientifically, and they were able to produce fire-bricks, by a judicious admixture of clays, which would fulfil certain definite conditions. That was done in Germany long before it was done in England, and he doubted whether it was done in England even now amongst a large proportion of fire-brick manufacturers. He thought that attitude was largely responsible for such progress as Germany might have made in chemical manufacture to the detriment of England. Naturally, the man in the established position tended to be content; but it behoved him to be alert, to realise what would be the attitude of his not yet established rival, and to take all practicable measures to preserve his supremacy. He sometimes wondered whether finance in Germany dealt with inventions and inventors quite in the same way as it did in England. Many inventions had simply been killed through the inventor getting into the hands of a syndicate who wished to use the invention merely as a means of making a large profit, and who had spoiled the invention by making it "stink in the nostrils of the investing public." He did not know whether that happened in Germany, but it happened in this country, and it was undesirable from the point of view of pure industry.

Mr. S. Evans quoted a case where gear wheels had been manufactured at a cost of 20s. per cwt., but that manufacture had to be discontinued because they were being supplied from Germany at 14s. per cwt., delivered into the works. Again, a company in London had formerly made a lot of tungsten, but had been driven from the market by German competition; he knew of three or four cases where the manufacture was now being carried on on an experimental scale, and it ought to attain to large proportions in time, for the English chemist could carry out the process just as well as the German chemist. In regard to the zinc industry' Germany was supplying more than half of the spelter, and the Germans had actually contracted for twenty years ahead for the production of all the zinc concentrates from Australia, but when war was declared and these supplies were interrupted a lot were diverted to this country. He could not see any difficulty in the way of manufacturing spelter in this country to compete with the Germans. Electrolytic zinc was produced in the United States, France, Belgium, and Germany, but the only firm he knew in this country who manufactured it was the firm of Brunner, Mond & Co. This zinc was used solely for making cartridge cases. Probably everyone would admit the advisability of some form of protection in order to foster the industries of this country. There was no doubt that a new industry, if it had to compete against some industry developed in Germany years and years ago, was on a weak footing indeed, and it was not surprising that financiers would not capitalise them.

With regard to chemical education in this country, his objection was that the chemist was treated purely and simply as a chemist, and had no idea of working costs. The only way they could get over that was by having a commercial man as manager. The modern chemist in works was looked upon as something a little less than the typist.

Mr. A. **Short** said that Germany had used the experience of older nations like ourselves, and all honour was due to her because she had come to the top. Perhaps we had lagged a little behind, but he thought that in time, even if we could not educate our boards of directors, we had future boards coming on, and they would realise, when they had to start in a small position like Germany had done, that it was only by studying the wants of the people for whom they manufactured that progress would be made. Our education of chemists was certainly far better than it used to be. There were many firms doing a lot of research work and many firms who were giving the chemist a good deal to say in the running of their works, and in time he thought that we should come to the top again.

Mr. S. H. **Collins** said that agriculture stood in a different position to other industries, although it was becoming very much a chemical industry. We were not entirely deficient in sources of potash. Agriculture did not grow on those big concentrations of capital which made it practical for any other business concern to employ a large amount of scientific research, and it had to leave that side of the question more to Government and private enterprise.

Mr. E. F. **Hooper** said that in their misfortunes in trade they always seemed to think that it was the other party who was making the mistake. One thing that was necessary was to get more effective help and support from our Government and its departments. The trouble which many chemical manufacturers experienced in shipping and exporting their products was greater in this than in many other European countries. Those in the chemical trade knew the considerable difficulty they had in getting real assistance from the Customs or from the Home Office authorities in making shipments of products abroad; he understood that, especially in Germany, the shipping and rail facilities and package facilities were always at the command of any chemical works. There was no doubt also that we had suffered a good deal from artificially assisted imported products in recent years. Another branch of our Government service which they had found unsatisfactory was our consular arrangements. A large number of our consular agents were Germans, and it was unlikely that they would give us every assistance for exporting our chemical products to a great and growing country like South America in preference to those of their own country. It was to be hoped that now our consular service would be served by Englishmen in every country. In England they were said to be under a very great and grievous difficulty with regard to the use of absolute alcohol in manufactures owing to the disinclination of the Government to assist chemical firms to use alcohol to the same extent as was allowed abroad. It was to be hoped that the Chambers of Commerce would secure an alteration in that direction, if the hindrance was a real one.

With regard to trade in Germany, they had to reflect that there was a more united system of dealing and manufacturing in Germany than in England. A large proportion of the German by-product firms dealing with tar were under one syndicate, and that undoubtedly enabled them to get facilities from their Government which we were entirely at a loss to obtain. There was a lack of cohesion among our chemical firms, and there was a great tendency to compete unduly one with another, whereas some system of co-operation and control such as they had in Germany would be of value both in cheapening working costs and in regularizing output. One could only hope that out of evil good would come, and there was no doubt that one of our trades might be immensely stimulated by the disastrous condition of things at the present time. He referred to the beet sugar industry. There was no finer climate or soil for the production of beet for sugar purposes, and the manufacture of sugar in our own country would provide work for an enormous number of men on farms, and a considerable source of potash would be obtained from the residues of beet sugar when manufactured on a large scale in this country. There was no reason why toughened glass should not be made here as well as in any other country. The manufacture of tungsten had been mentioned; there were many alloys which this country, which is pre-eminently the home of the finest steel, ought to be able to produce.

Professor H. **Louis** said that the discussion had extended over a wide range of subjects, but there seemed a pretty definite consensus of opinion that in many directions at any rate Germany had distinctly the better of us in scientific and technological manufactures. The blame had been distributed among our Government, our manufacturers, our financiers and our method of education; rather less stress had been laid upon the question of natural advantages or disadvantages, and he was personally inclined to think that those of Germany had been somewhat overlooked; for example, here were the enormous natural deposits of potash salts on a scale which, as far as he knew, were not to be found anywhere else in the world. It might be possible to extract potash from such bodies as potash felspar, and if there was a dearth of potash it might stimulate work in that direction. Zinc manufacture was a fair example of how natural advantages sometimes work out. Germany was a zinc manufacturer long before zinc was known through the production of calamine brass. England, however, was the first to take up the manufacture of zinc as such by what was known as the old English process. Then came Belgium and Germany, and these had the advantage of large deposits not only of zinc ore but above all of high-class fire-clays, and England lost its place in the zinc industry through no fault of her manufacturers, but because she had not those particular high-class clays. But the balance has since been redressed now that it has been found an admirable retort can be made from carborundum. That, of course, brought in another form of natural advantage, for they required a cheap source of electricity, and America had now taken a prominent place in zinc manufacture. It was clear that in these discussions one must not forget the natural advantages of the countries concerned.

With regard to the other parties who had to bear their share of the general blame, he thought that it was quite justifiable to say that our Government was in various ways responsible for it. Possibly that was inevitable in a system of party Government. To what extent our manufacturers were to blame was very difficult to decide. It was certain that for a long time they did not appreciate the advantages of technical education. But they had factories that worked steadily and paid well, and they therefore stuck to their old well-tried methods, and if any of them were manufacturers in the same position they would probably do the same thing.

To what extent our methods of education might be to blame it was also very difficult to say. Germany commenced by educating in the truest sense of the word. She worked at science for the sake of science itself.

Before 1870 Germany was divided into small kingdoms the rulers of each of which required to be surrounded by the shrewdest and most capable men they could get, and this gave an immense impetus to national education;

add to this the undoubted bent of the German mind towards science, and it is obvious why science was pursued for its own sake. It was only afterwards that the German manufacturers began to discover that there was money in this same science, and now Germany had ceased to pursue science except for what she could make out of it, and he was inclined to think there were signs of a corresponding decadence in German science, not altogether to our disadvantage. Finally, came the very difficult question to what extent the financiers were to blame. In Germany they had a large number of industrial banks, banks that were prepared to subsidise industries, even young and growing industries almost to any extent, and unquestionably that had been an enormous advantage to German industry. He had come across cases where English firms had been beaten out of the market because the Germans had at their backs the huge capital which their banks were ready to offer, and he had felt the enormous power which that attitude of German bankers gave the Germans, but on the other hand it brought with it a corresponding danger. He remembered some eight or nine years ago a terrible financial crisis caused by the failure of one large German firm which had been subsidised by the banks, and that crisis very nearly brought about a financial panic in Germany. Upon the whole he thought it would be better if some banks were prepared to pursue a more open policy in that respect and laid themselves out for the support of industrial undertakings; but he admitted that it was a very debatable point. He was very much at one with Mr. Martin in objecting to the proposed subsidy for the dye industry by the Government. It was to him an entirely false policy, for if it was a bad business why should the Government put our money into it? If, on the other hand, it was a good business, there would be no difficulty in finding capital for it. He could not see that policy was a sound one or one to be recommended.

Mr. Martin then briefly replied to the discussion, and the proceedings terminated.

Lectures.

THE SUPPLY OF CHEMICAL PRODUCTS TO BRITAIN AND HER DEPENDENCIES.

Delivered before the Royal Society of Arts on Nov. 25, 1914. By Sir William A. Tilden. J. Roy. Soc. Arts, 1914, **63**, 26—37.

(Abstract.)

After the days of Lavoisier, and during the earlier part of the nineteenth century, the foundations of theoretical chemistry were laid by the efforts of the chemists of England, France, and Sweden, including Davy, Faraday, Dalton, Gay-Lussac, Dumas, and Berzelius. There were no German chemists of the front rank in those days, the only fundamental discovery of great importance attributed to Germany being the discovery of isomorphism by Mitscherlich in 1819. Thus, whilst acknowledging the brilliant services to chemistry of such men as Liebig, von Bayer, and Fischer, it is clear that the fundamental principles underlying chemical theory have been established almost entirely by the chemists of other nations.

In 1862, A. W. Hofmann said that the British had maintained their pre-eminence among the chemical manufacturers of the world, and at about the same time W. Gossage prepared the following statistics relating to the alkali trade, beside which are placed those collected by C. Allhusen in 1852, from 81% of the manufacturers of the United Kingdom:—

	1852.	1861.
	tons.	tons.
Soda ash	71.193	156.000
Soda crystals	61.044	104,000
Bicarbonate..............	5.762	13,000
Bleaching powder	13.100	20.000
Estimated total value	£1,250,000	over £2,000,000

In 1907 soda compounds, excluding bleaching powder and chromates, were produced in the United Kingdom to the value of £3,390,000, whilst the value of the bleaching powder made was £527,000; imports of these products in 1912 from Germany were £8700 and £44,600 respectively. These figures show that British manufacturers have been able, up to the present, to hold their own against foreign competition in these chemicals, and a similar remark applies to aluminous compounds, coal-tar products not dyes, cyanides, sulphuric acid, and other acids.

The immense advances made in all civilised countries have brought increasing demands for a variety of products, many of which are the outcome of recent chemical progress: these include coal-tar dyestuffs, drugs, antiseptics, essential oils, photographic chemicals, explosives, and analytical and laboratory reagents. The sources of supply of dyes, drugs, photographic chemicals, and perfumes in the United Kingdom are seriously inadequate, a large proportion having been obtained from Germany. Thus, in 1913 we imported from Germany artificial dyestuffs to the value of £1,730,278, and "drugs, unenumerated, including medicinal preparations," £332,464. Our exports to Germany of dyes and other chemicals from coal tar amounted in the same year to £24,691, whilst our production of dyestuffs in 1907 was valued at £373,000. There has been no appreciable production of fine chemicals for analysis in this country.

The German chemists have been boasting that, having secured the trade in fine chemicals and dyes, they will now attack the heavy chemical business. In this connection it is to be noted that the export of sulphuric acid from Germany in 1912 was three times as large as that from the United Kingdom in 1913. The successful establishment in Germany of works for the production of ammonia from its elements, and for the fixation of atmospheric nitrogen as cyanamide, is also very significant.

Though the development of scientific teaching and research in this country has not been so marked as in Germany, there is here considerable activity in chemical research, but further co-operation between industry and science is needed; the secret of the success of German chemical factories has been the employment of the best available scientific skill and the constant appeal to scientific research. One of the most notable instances of this has been the production of synthetic indigo, the ultimate success of which was attributed by Brunck to the co-ordination of intellectual labour and the industry of many men for a number of years. British chemists, including Perkin, Meldola, and Green, agree that Germany's success has been due to her better appreciation of the value of science.

To remove reproach from British chemical industry and to render the Empire independent of supplies from foreign sources, it will be necessary to have many first-rate chemists, a few engineers, plenty of capital, and some good business men: a combination of these in due proportion is certain of success. If the demand for scientific assistance were more general, the supply of well-qualified men would increase and greater attention would be given by teachers to the industrial side of the subject. Further, the remuneration offered to the chemist is often insufficient, and the employer frequently expects immediate profitable returns from the engagement of a scientific man. In German works research and manufacture are regarded as inseparable.

The establishment of new industries requires assistance from the State, and encouragement is already promised for the dye industry; but remembering that the manufacturer of dyestuffs depends on a number of intermediate compounds, the production of which is associated with other chemical manufactures, it is to be hoped that temporary protection will be extended beyond the immediate field of the colour-maker.

Finally, when the war is over, everyone should demand that business at home shall be limited to British goods, in spite of the powerful organisation and long experience behind the German chemical manufacturers.

Discussion.

The Chairman (Sir William Ramsay, K.C.B.) said that it was for the scientific and technical chemists of this country to outline the steps necessary to recover their ormer supremacy. German chemical industries were nanaged by specialists, aided by a highly trained staff of cientific, technical, commercial, and legal men, and were rotected by fiscal and other legislation, by low freights, nd by bounties. Such competition must be met by o-operation amongst chemical manufacturers, for example y smaller works combining to obtain efficient laboraories, and by protecting our industries by means similar o those adopted in Germany.

Prof. J. J. **Dobbie** said that as regards the supply of rained chemists, this country was in a better position han it had ever been. In the smallest of the Scottish niversities, twelve research students were assisting in he production of certain drugs required by the Army nd Navy. Unless chemical manufacturers were prepared o avail themselves of scientific assistance, and to renunerate it adequately, little progress could be made. he Government Laboratory had recently applied to everal manufacturers for chemicals previously made broad, but no one would undertake the manufacture, nd finally it had been made in the Laboratory itself. hat indicated either lack of suitable men in the works, or nwillingness to devote the time to the problem. What as needed here was proper organisation.

Mr. A. E. **Berry** said that many manufacturers were andicapped by the restrictions with regard to duty-free pirit.

Prof. A. G. **Green** said that the Germans had considered t worth while to pay to obtain knowledge, whilst we had ot. In addition to the difficulties with regard to alcohol, he British manufacturer was handicapped by the price of uch products as ether and ethyl acetate, which had to be ade from industrial alcohol. However, the question of lcohol was not of premier importance; the question of he employment of chemists came first.

Mr. A. C. **Chapman** said that it was necessary to educate any British manufacturers and also the British public. he brewing industry had recognised the value of science.

Mr. W. F. **Reid** said there were many inventions made this country but worked abroad. The British Governent had at first refused to adopt smokeless powder for he Army, because, if they had done so, all the rifles would ave had to be altered. The commercial aspect of the uestion was of the greatest importance. It would be seless to invest large sums in plant for new manufactures nless such manufactures could be protected in some way fter the end of the war.

Col. C. E. **Cassal** referred to the very low salaries offered and accepted by trained chemists.

The **Author** replied briefly to the various points raised.

HE PREPARATION AND COMMERCIAL USES OF HYDROGEN.

By A. W. Crossley. Pharm. Soc., April 21, 1914. Pharm. J., 1914, 92, 604—607, 637—640, 676—679.

It is only within the last ten years or so that hydrogen as become a substance of great commercial importance.

The methods by which hydrogen is now made on the rge scale may be divided into four groups :—1. The ction of acids on metals ; 2. The action of steam on etals and other substances ; 3. Electrolytic methods ; . Other methods.

1. *Action of acids on metals.*—In some industries and for lling balloons in stationary military camps hydrogen is ade by the action of dilute sulphuric acid on iron, but ere are many objections to this method, not the least eing the enormous quantities of material which have to e used. For example, a military airship of no very ceptional capacity requires from 250,000 cubic feet (about 000,000 litres) to 500,000 cubic feet of hydrogen to inflate , which would necessitate, taking the lower figure of pacity, the use of about 18 tons of iron and 31 tons of lphuric acid.

2. *Action of steam on metals, etc.*—The two most idely employed methods coming under this head are the ction of steam on iron, giving oxide of iron and hydrogen, and the action of steam on coke, producing the so-called water-gas,

$$C+H_2O=CO+H_2$$

which contains on the average H 48, CO 43, CO_2 4, N 4%, together with small amounts of O and CH_4. The carbon monoxide and other impurities can be removed by a variety of methods; for example, Frank (Fr. Pat. 371,814, 1906; this J., 1907, 408) suggests passing the dried water-gas over calcium carbide at above 300° C., when carbon monoxide and dioxide react with the carbide, forming calcium oxide, calcium carbonate, and carbon :—

$$CaC_2+CO=CaO+3C$$
$$2CaC_2+CO_2=2CaO+5C$$

and nitrogen is absorbed with formation of calcium cyanamide :—

$$CaC_2+N_2=CaNCN+C$$

In order partially to remove the oxides of carbon the water-gas may first be treated with solvents or strongly cooled to liquefy them. Jouve and Gautier (Fr. Pat. 372,045 of 1906; this J., 1907, 401) pass the gas through a porous partition of unglazed porcelain so as to separate the hydrogen by reason of its more rapid rate of diffusion. A single passage through the partition reduces the content of carbon monoxide from 45 to 8%. The Cie. du Gaz de Lyon (Fr. Pat. 375,164 of 1907; this J., 1907, 863) pass water-gas mixed with steam at a temperature exceeding 400°—500° C. over a catalyser, such as oxide of iron, when the carbon monoxide is replaced by an equal volume of hydrogen :—

$$CO+H_2+H_2O=CO_2+2H_2$$

and the carbon dioxide produced is removed by lime. (See also Elworthy, Fr. Pat. 355,324 of 1905; this J., 1905, 1164). The Griesheim Elektron Company (Eng. Pat. 13,049 of 1912; this J., 1913, 278) pass water-gas, mixed with steam, into a heated retort charged with quicklime, when calcium carbonate is formed :—

$$[H_2+CO]+CaO+H_2O=CaCO_3+H_2+H_2$$

The elimination of the monoxide is very complete, and the resulting hydrogen (containing the nitrogen originally present in the water-gas) costs about one penny per cubic metre.

Some of the working methods may be briefly described as follows :—

The Linde-Frank-Caro Process (compare Linde, this J., 1911, 746; also Frank, this J., 1911, 893) starts with water-gas, having practically the composition indicated in Column 1 :—

—	1.	2.	3.
Hydrogen	48—54%	97—97·5%	99·2—99·4%
Carbon monoxide	42—44%	1·7—2%	Nil
Carbon dioxide	2—5%	Nil	Nil
Nitrogen	3—5%	1—1·8%	0·6—0·8%
Oxygen, marsh gas, sulphur and phosphorus compounds	Variable amounts	Nil	Nil

The carbon dioxide is removed by using absorbents, such as lime, caustic soda, or more simply by a solution of caustic soda under the pressure necessary for separating the water-gas into its constituents. This separation is based on the fact that hydrogen boils (— 253°) much lower than either carbon monoxide (— 192°) or nitrogen (— 196 C°). Hence if the gaseous mixture be cooled with liquid air, carbon monoxide, nitrogen, and other impurities are condensed, while hydrogen remains in the gaseous form. There is thus obtained one portion of the water-gas very rich in carbon monoxide (80—85%), which can be burnt in a gas-engine serving to drive the plant; and a second portion, very rich in hydrogen, with composition given in Column 2 above. Further purification can be effected by treatment with soda-lime, when the whole of the carbon monoxide is removed, and the resulting gas has the composition indicated in Column 3 above. The inventors of the process claim that hydrogen produced in this way contains no heavy hydrocarbons, oxygen, or compounds of sulphur and phosphorus, and that it can, therefore, be used for catalytic reactions or for filling balloons, because it contains nothing liable to corrode balloon fabric or to cause explosions. The cost of producing the gas with the composition given in Column 2 is 1½d. per cubic metre, and the gas of the composition indicated in Column 3, 2d. per cubic metre. The gas can be stored in gasometers or, as it issues from the apparatus under about 50 atmospheres pressure, in compression cylinders.

The Messerschmitt patents. (Eng. Pat. 12,117 of 1912; Fr. Pats. 444,105 of 1912; 461,480, 461,623 and 461,624 of 1913; Ger. Pats. 254,222, 263,390, 263,391, 268,062 and 268,339 of 1912; this J., 1912, 1079, 1126; 1913, 351, 944; 1914, 136, 137, 201, 313) combine the production of hydrogen by the action of steam on iron and reduction of the resulting iron oxide by water-gas. These two reactions, which take place between 700° and 800° C., are known respectively as the gassing or oxidation period and the reduction period. They are carried out alternately so long as the reactions take place with sufficient speed, averaging about ten minutes and twenty minutes respectively. The principles of the process have been known for a long time, and are the subject of numerous patents (Lane, Eng. Pat. 17,591 of 1909; Dieffenbach and Moldenhauer, Fr. Pat. 444,044 of 1912; this J., 1910, 1057; 1912, 1126); but there are many technical difficulties which up to the present have not been mastered, more particularly that of heating the contact mass uniformly and sufficiently speedily without running the risk of over-heating and melting it. The Messerschmitt patents claim to have overcome these difficulties by a series of details of furnace construction, ensuring even heating and heat economy. On leaving the generators the hydrogen is purified by spraying with water to remove dust, and is then led through chambers filled with bog ore and lime to remove traces of sulphur compounds and carbon dioxide. The gases used for heating and reducing, which do not cost more than one-halfpenny per cubic metre of hydrogen produced, are carefully purified, thus rendering the life of the contact mass a very long one, and securing, with the small amount of further purification already mentioned, an almost chemically pure hydrogen containing only traces of nitrogen.

Another method makes use of the application of high pressure in promoting chemical reactions whereby it is possible to retain the liquid state from the boiling point up to the critical point, and thus to utilise the physical properties of a liquid at high temperatures, causing reactions to take place which cannot be carried out at low temperatures. Led by the assumption that in the presence of a metal water in the liquid state might be made to decompose into hydrogen and oxygen, Bergius (this J, 1913, 462) has investigated and patented a process for producing hydrogen in large quantities by the action of water on iron. The reaction takes place quantitatively in accordance with the equation :—

$$3Fe+4H_2O=4H_2+Fe_3O_4$$

and is carried out at 300° to 340° C. The oxide of iron is produced as a very fine powder, which can easily be reduced to the metallic state by either carbon or carbon monoxide. The speed of the reaction increases with increase of temperature, and is also affected by the presence of such substances as sodium chloride, ferrous chloride, or a metal such as copper, as can be seen from the results detailed in the following table :—

	Temp.		Quantity of hydrogen per hour. c.c.
Iron and pure water	300°	..	230
Iron and pure water + $FeCl_2$	300°	..	1,390
Iron and pure water + $FeCl_2$ + Cu	300°	..	1,930
Iron and pure water + $FeCl_2$ + Cu	340°	..	3,450

Within the limits practically obtainable, the speed of the reaction is so great that in a vessel of 10 gallons capacity about 3000 cubic feet of hydrogen can be generated per day. Since iron and water are the raw products, it is possible to obtain an extremely pure form of hydrogen, mainly because the carbon and sulphur compounds in the iron are practically unattacked by the water. A sample of the gas has been analysed by passing 30 litres over heated copper oxide and weighing the water and carbon dioxide formed. In a second experiment 200 litres of hydrogen were passed under pressure through a copper coil cooled in liquid air and the condensed fraction analysed for carbon dioxide, carbon monoxide, saturated and unsaturated hydrocarbons, with the following results :—H, 99·9495; CO, 0·0011; C_nH_{2n+2}, 0·0416; unsaturated hydrocarbons, 0·0078%. Advantages claimed for the method are that as the reaction is vigorous the hydrogen is obtained under high pressure (up to 300 atmospheres: Ger. Pat. 254,593 of 1911 and Fr. Pat. 447,080 of 1912; this J., 1913, 195, 364), and may be directly filled into cylinders without previous compression; further, that compared with the latest and cheapest technical process for the production of hydrogen, that of Linde-Frank-Caro, it gives a very much purer gas without cost of purification, without cost of compression, and with a total expense of energy 60% less than is needed in the Linde process. The gas containing less than 1·01% impurities, and costing about three-farthings per cubic metre, is now being produced at a factory in Hanover. Bergius has also patented another process (Ger. Pat. 259,030 of 1911; this J., 1913, 657), in which a mixture of carbon dioxide and hydrogen is produced by heating together coke and water in presence of thallium chloride. The carbon dioxide is removed by lime, and the resulting hydrogen is obtained absolutely pure and under a pressure of more than 100 atmospheres.

3. *Electrolytic methods.*—One of the main difficulties met with in the preparation of hydrogen by the electrolysis of water or some suitable electrolyte, is that a mixture of oxygen and hydrogen is given off at both electrodes. The hydrogen contains about 1% of oxygen and the oxygen about 2% of hydrogen. Depending on the use to which the hydrogen is to be put, this amount of oxygen may become very dangerous, as for example, in the synthetic preparation of ammonia, where the mixture of gases is heated to a fairly high temperature. In order to avoid this, the electrodes may be separated by a diaphragm, which, however, increases the resistance in the cell to such an extent that the efficiency of the apparatus is seriously reduced. The difficulty has been overcome in a variety of ways, and in the Garuti system (see Eng. Pats. 23,663 of 1896, 12,950 of 1900, 2820 of 1902, and 27,249 of 1903; this J., 1897, 337; 1900, 1121; 1902, 778; 1905, 94) which is used in Italy, the diaphragm consists of iron sheets about 1 mm. thick, covered on both sides with a metallic net to facilitate the separation of the small bubbles of gas which collect. The electrolyte is a 26% solution of potassium hydroxide, which must be very pure as if it contains chlorides or sulphates, Cl and SO_4 ions are formed, which attack the electrodes. Other forms of electrolytic apparatus are described in Fr. Pat. 355,652 of 1905; Ger. Pat. 198,626 of 1906, Fr. Pat. 397,319 of 1908; this J., 1905, 1240; 1908, 946; 1909, 799).

The Elektron Works at Griesheim on Rhine prepare hydrogen by the electrolysis of potassium chloride. Three important products—hydrogen, chlorine, and potassium hydroxide are thereby made in one operation. The Maschinenfabrik Oerlikon use a solution of potassium carbonate as electrolyte, and the Heraeus Company in Hanau use a 20% solution of potassium hydroxide maintained at 60—70° C. Both firms require an expenditure of six kilowatt-hours per cubic metre of hydrogen. Where electric power costs £4 per horse-power year, as is frequently the case in Germany, the electric energy necessary for the production of one cubic metre of hydrogen amounts to about three-farthings.

Large quantities of hydrogen are also formed in various electrolytic processes, such, for example, as the preparation of sodium hydroxide.

4. *Other methods.*—In this connection may be mentioned the action of water on calcium hydride, CaH_2, prepared by passing electrolytic hydrogen into metallic calcium heated in an electric furnace (Fr. Pat. 327,878 of 1902; this J., 1903, 950), and the so-called hydrolith and hydrogenite processes. *Hydrolith* is a white crystalline powder consisting of about 90% calcium hydride, the remainder being oxide or nitride. When treated with water about one cubic metre of hydrogen is evolved from each kilo. of

hydrolith. *Hydrogenite* consists of 25 parts of ferrosilicon, 60 parts of sodium hydroxide, and 20 parts of slaked lime: when suitably ignited, it reacts with production of hydrogen, and the silicates of sodium and calcium. One kilo of hydrogenite yields from 270 to 370 litres of hydrogen.

Pictet (Eng. Pat. 14,703 of 1911; this J., 1912, 686) prepares a mixture of hydrogen and carbon monoxide in any desired proportion (by regulating the supply of water) by heating together a mixture of water and hydrocarbon vapours, such as petroleum. Every litre of petroleum furnishes about 3000 litres of gas. (See also Badische, Fr. Pat. 463,114 of 1913; this J., 1914, 313.)

The Carbonium Company at Friedrichshafen, the headquarters of the Zeppelin dirigible balloon management, prepare hydrogen by decomposing acetylene electrically. The carbon is produced in such a fine state of division that it commands a high price as a pigment. (Compare also Pictet, Fr. Pat. 421,838 of 1910; this J., 1911, 542).

Numerous other methods have been suggested, but it would hardly seem likely that many of them could really be considered as sources of cheap hydrogen when compared with some of those already mentioned. Uyeno (Eng. Pat. 11,838 of 1912; this J., 1913, 289) treats each part of an alloy of 78—79 parts Al, 1—15 parts of Zn and 0·5—7 parts of Sn, with 0·025—0·12 part of Hg. After heating to as high a temperature as possible, without volatilising the mercury, the mass is treated with hot water.

Teissier and Chailláux (Fr. Pat. 447,688 of 1912; this J., 1913, 234) heat a mixture of barium sulphate and manganous oxide to a red heat, finally to a white heat, and pass steam under pressure over the resulting mass, when the following reactions are stated to take place :—

$$BaSO_4+4MnO = BaS+4MnO_2$$
$$BaS+4MnO_2=BaS+4MnO+2O_2$$
$$BaS+4MnO+4H_2O=BaSO_4+4MnO+4H_2$$

Jaubert (Fr. Pats. 427,191 of 1910; 438,021 of 1911; this J., 1911, 1058; 1912, 536) prepares hydrogen by the ignition and autocombustion of mixtures containing excess of a combustible body, capable of decomposing steam at high temperatures, with an oxidising agent to maintain combustion, and a substance capable of evolving steam when heated. Such mixtures are: powdered iron 20 parts, slaked lime 10 parts, potassium perchlorate 6 parts; or ferrosilicon 20 parts, lead monoxide 10 parts, and soda lime 60 parts.

Uses of hydrogen.

Hydrogen is used as a combustible on account of the high temperature attainable when it is burnt in presence of oxygen (up to 2800° C.). The so-called oxy-hydrogen flame is employed, for example, in the fusion and welding of platinum and in uniting the edges of lead sheets for making vessels to hold acids. The best proportion in which to use the gases for welding is one part of oxygen and four parts of hydrogen; if the proportion of oxygen is increased, the flame acquires an oxidising action. The oxy-hydrogen flame has now been largely replaced by the oxy-acetylene flame, because the latter yields a higher temperature, and whilst in the reducing flame about 4 cubic metres of hydrogen are required for one cubic metre of oxygen, only 700—800 litres of acetylene are necessary. The oxy-hydrogen flame is also employed in working fused quartz for making laboratory apparatus or quartz mercury lamps.

In the manufacture of tungsten filament lamps an inert atmosphere is required in which to heat the filaments to a high temperature during their final treatment. Generally a mixture of hydrogen and nitrogen in equal volumes is employed, and it is of importance that the hydrogen should be very pure on account of the tendency of the filaments to oxidation.

Hydrogen is now largely used for the filling of balloons and dirigible airships. It is calculated as possessing a lifting capacity of 1 kilo. per cubic metre, and must be of a sufficient degree of purity not to attack the balloon fabric. It is recorded (this J., 1907, 1130) that a balloon burst at Milan in 1906, the fabric of which was marked with spots which could be easily torn. These were proved to have been caused by phosphoric and arsenic acids, arising from the oxidation of phosphine and arsine in the hydrogen with which the balloon had been filled. The quantities of hydrogen required for the filling of airships are on the manufacturing scale, and, moreover, the supply must be regular because of the high rate of diffusion of hydrogen; though improvements in the manufacture of balloon fabrics are now largely minimising this objection.

In the last decade two entirely new industries have sprung into existence, depending on the behaviour of hydrogen in presence of certain catalysts. These are :—

(1) The synthetic production of ammonia directly from nitrogen and hydrogen. (2) The hardening of fats.

In 1897 Sabatier and Senderens discovered a general method for hydrogenating volatile organic substances, based on the employment of certain metals in a fine state of division as catalysers. Numerous detailed researches have appeared on the subject in the *Comptes Rendus* and the *Bulletin de la Société chimique de France* by Sabatier and Senderens (1897—1905), Sabatier and Mailhe (1904—8), and Sabatier and Murat (1912). Sabatier and Senderens have also published a résumé of their researches in the *Annales de Chimie et de Physique* (1905 [8], **4**, 319; 1909 [8], **16**, 70); Sabatier has delivered a lecture on the subject before the German Chemical Society (*Ber.*, 1911, **44**, 1984), and a still more detailed account is to be found in the recently published book entitled "La Catalyse," by P. Sabatier (see also this J., 1914, 733). The process consists essentially in passing the vapours of a substance mixed with excess of hydrogen through a tube containing a metallic catalyser, such as platinum black, nickel, cobalt, iron, or copper, maintained at a suitable temperature, which may be the ordinary temperature, but which is in general from 150—200° C., 180° C. being frequently the most suitable. Of these five metals, nickel is the most active, and together with cobalt the only one capable of producing certain hydrogenations such as that of the benzene ring; copper is the least active, platinum and iron being intermediate between cobalt and copper. The hydrogen must be rigorously purified from such substances as hydrogen sulphide, arsenide, phosphide, and chloride. This is accomplished by passing it through a long glass tube containing copper turnings heated to redness, which arrests the major portion of the impurities; then through a long tube filled with moistened potassium hydroxide to arrest acid vapours or hydrogen sulphide, and finally drying the gas. The activity of the nickel varies very much according to the nature of the oxide from which it is prepared, and the conditions under which the oxide is reduced. Nickel obtained by reduction at a bright red heat is practically inert as a catalyser, whereas when produced by precipitating the hydroxide from the nitrate, drying, and reducing at 250° C. it is excessively active, but also very variable in character. The best product is obtained by dissolving commercial nickel in nitric acid, free from hydrochloric acid, calcining the nitrate at a dull red heat, and reducing the oxide so obtained at about 300° C. Such nickel is capable of producing a great variety of reactions, and maintains its activity for a very long time. If the reduction is carried out above 350°, the nickel is of little use for reducing substances containing the benzene ring, but at 250° or 280° C. the resulting substance is quite active in this respect. The presence of infinitesimal amounts of chlorine, bromine, or iodine poisons the catalytic effect of nickel, and therefore the metal should never be prepared from oxide precipitated from the chloride. The catalytic activity of nickel exhibits three stages, an initial short period during which the catalyst adapts itself to its function, a normal period of activity and a period of decline. The second period of normal function is generally very long, and would probably be indefinite if the metal did not come in contact with any traces of substances capable of altering its surface, as may easily be derived from the hydrogen used, from the substance itself or from the product of the reaction. Traces of sulphur or of the halogen elements (as already mentioned) completely suppress the activity of nickel; for example, benzene which has not been completely purified from thiophene cannot be transformed into cyclohexane, and the presence of a minute trace of bromine in phenol prevents the latter being changed into cyclohexanol. When carefully prepared the nickel can, however, be used for a very long time, and Sabatier and Senderens quote an instance where they employed the same tube of nickel for transforming benzene into cyclohexane for more than a month. Sooner or later its action becomes enfeebled (the more active the metal, the more rapid the change), due to traces of toxic substances, which gradually accumulate, and most frequently to small amounts of non-volatile tarry matters, which condense on the active surface and so prevent contact with the hydrogen and the substance under treatment. When an enfeebled specimen of nickel is dissolved in dilute hydrochloric acid there is always a fetid smell of hydrocarbons, and a deposit of brown viscous matter. The same effect is noticed when the reaction gives rise to substances which are only slightly volatile at the temperature of the reaction, and which gradually impregnate the metal and prevent its activity. For example, in the hydrogenation of aniline at 190° C. there is mainly produced cyclohexylamine, $C_6H_{11}NH_2$, boiling at 134° C., but also two non-volatile amines, dicyclohexylamine, $(C_6H_{11})_2NH$ and cyclohexylaniline, $C_6H_{11}NH{\cdot}C_6H_5$, which boil above 250° C. It is for this reason that it is necessary to avoid allowing the metal to become moistened with the liquid under treatment, which may be caused by an excess of the substance or by a lowering of the temperature of the reaction tube.

Hydrogenations can only take place within a certain range of temperature, and both the substance to be transformed and the transformation product must be kept in the state of vapour. Within a certain limit, the higher the temperature the greater the acceleration of the reaction, but changes of temperature may produce profound changes in the course of the reaction. Thus benzene can be converted into cyclohexane, C_6H_{12}, by hydrogen in presence of nickel at 70° C., the amount formed increasing with the temperature and reaching a maximum at 180°—200° C. Then the amount gradually decreases to 300° C., at which temperature the reaction no longer takes place; on the contrary, cyclohexane is decomposed into benzene and hydrogen, or into benzene and methane, according to the equation:—

$$3C_6H_{12}=2C_6H_6+6CH_4.$$

Above 300° C. the reaction is limited to the transformation of benzene into methane. When a substance is capable of adding on several molecules of hydrogen, this can often be carried out in stages by a choice of temperature, thus anthracene, $C_{14}H_{10}$, at 180° C., is changed into the perhydride, $C_{14}H_{24}$; at 200° C. into the octohydride and at 260° C. into the tetrahydride. The easiest reactions to carry out are those capable of being brought about over a large range of temperature such as the reduction of an ethylenic linkage or of certain nitro-derivatives. The most difficult are where the range of temperature is narrow, as in the hydrogenation of the aromatic nucleus, and, above all, with the diphenols or pyrogallol.

The reactions may be divided into four classes:—1. Reduction without fixation of hydrogen. 2. Reduction effected with fixation of hydrogen. 3. Direct fixation of hydrogen, as, for example, at a double bond. 4. Hydrogenations effected with decomposition of the molecule.

1. Reduction without fixation of hydrogen is of little importance. It may be exemplified by the conversion of nitrous oxide into nitrogen and water without the formation of either ammonia or hydrazine.

2. Reduction effected with fixation of hydrogen is illustrated by the behaviour of carbon monoxide:—

$$CO+3H_2=H_2O+CH_4.$$

The reaction commences at 180°—200°, and is rapid at 230°—250° C., so that with a mixture of 3 vols. of hydrogen and 1 vol of carbon monoxide, it is practically complete, and pure methane results. Below 250° C., the nickel can be used indefinitely and is completely soluble in dilute hydrochloric acid without leaving any carbonaceous residue. Above 250° C. there is a complication due to the reaction:—

$$2CO=C+CO_2,$$

and at 380°, when using the mixture of gases which is totally converted into methane at 250° C., a mixture is formed containing in 100 vols., 10·5 vols. CO_2, 67·9 vols. CH_4, and 21·6 vols. H_2. Carbon dioxide is likewise converted into methane,

$$CO_2+4H_2=CH_4+2H_2O,$$

and at 300° C., using excess of hydrogen, the reaction can be made to furnish almost pure methane, by washing the resulting gases with potassium hydroxide, drying and liquefying, under conditions such that any hydrogen present in the mixture is not condensed, and therefore escapes. The production of methane by the direct hydrogenation of carbon monoxide or dioxide can be utilised for the industrial preparation of a gas possessing very high calorific power and capable of being used for heating or lighting (Int. Congress Applied Chem., Rome, 1906, 4th Section, 188). Several methods have been suggested, of which the most promising would appear to be the preparation of water-gas at as high a temperature as possible, when it consists of almost equal volumes of carbon monoxide and hydrogen, with very small amounts of nitrogen and carbon dioxide. By a process of cooling three-quarters of the carbon monoxide can be liquefied, giving a gas of the composition one vol. of carbon monoxide and 4 vols. of hydrogen, which, when passed over nickel at 200°—250° C., is converted into a mixture of equal vols. of methane and hydrogen. The refrigeration has the further effect of condensing the sulphur compounds present in water-gas, which would poison the nickel.

3. The preparation and careful study of the properties of hydrogenated aromatic, or hydroaromatic, compounds have long been of the greatest importance on account of their close connection with such substances as the naphthene hydrocarbons of petroleum and the naturally occurring terpenes and camphors. Many hydroaromatic substances have been prepared by indirect methods, but their direct preparation from aromatic compounds, in many cases, has been rendered possible by Sabatier and Senderens' reaction. In the great majority of cases the hydrogenation of the aromatic nucleus by hydrogen in presence of finely divided nickel takes place at about 180° C. without any considerable amount of side reactions, and consequently the products are obtained in very good yields. (Compare Skita and Ritter, Ber., 1911, **44**, 668.) Below 250° C. toluene, the three xylenes, mesitylene and pseudocumene give, in almost quantitative yields, the corresponding methyl-cyclohexanes. Traces of unaltered aromatic hydrocarbons are always present, but they are easily removed as nitro compounds by treatment with a mixture of 1 vol. of concentrated nitric acid and 2 vols. of concentrated sulphuric acid. In the case of aromatic hydrocarbons with a long side chain, there is always produced, besides the principal normal product, more or less of the saturated hydrocarbons with shorter side chains, *e.g.*, ethylbenzene gives ethylcyclohexane and some methylcyclohexane; propylbenzene gives propylcyclohexane together with some methyl- and ethyl-cyclohexanes. The amounts increase with rise in temperature, and it is therefore important to limit the temperature to 180° C. in these reactions. Phenol is easily converted into cyclohexanol at 180°: thymol and carvacrol into the corresponding methylisopropylcyclohexanols at 180°—185° and 195°—200° C. respectively.

4. The phenomenon of hydrogenation accompanied by decomposition of the molecule largely depends on the temperature. Generally speaking, between 300° and 350° C. cyclic hydrocarbons are broken down into small molecules, principally methane (see benzene, above). Acetylene gives at quite a low temperature ethane and small amounts of higher gaseous and liquid hydrocarbons. By carrying out the reaction at 200° C., Sabatier and Senderens obtained a liquid consisting principally of pentane and its homologues, together with small quantities of ethylenic hydrocarbons and traces of aromatic hydrocarbons. The liquid in density, odour, and fluorescence resembled Pennsylvanian petroleum; whereas the same reaction without the use of any hydrogen and at 200°—300° C. gave rise to a liquid consisting principally of aromatic hydrocarbons and strongly resembling Caucasian petroleum. On these facts Sabatier and Senderens have formulated a theory of the formation of natural petroleum. They

presume that in the interior of the earth large masses of the alkali metals and metals of the alkaline earths exist, together with their carbides. These, when acted upon by water vapour, would liberate hydrogen and acetylene respectively, and reactions similar to the above would take place. If the hydrogen was in large excess, then on coming in contact with nickel, cobalt, or iron at temperatures lower than 200° C., American petroleum would result, together with large quantities of combustible gases (hydrogen, methane, ethane, etc.), such as are actually met with at Pittsburgh. If acetylene encountered the metals without any appreciable amount of hydrogen, there would result principally aromatic hydrocarbons or Caucasian petroleum. Intermediate conditions would give rise to the petroleums of Galicia or Roumania.

Finely divided cobalt, such as is produced by the reduction of its oxide, may be substituted for nickel in all of the reactions which the latter is capable of bringing about, but its activity is less marked than that of nickel, and in general higher temperatures are necessary. Finely divided iron, obtained by the reduction of its oxides, can be substituted for nickel in many reactions, but not in all. For example, it is possible to use it for reducing ethylenic hydrocarbons, acetylene, aldehydes, or ketones, but it is useless for transforming carbon monoxide or dioxide into methane, and also for the fixation of hydrogen to the aromatic nucleus. Another disadvantage is that the oxides must be reduced at temperatures between 400°—450°, which takes six or seven hours to accomplish, for if the temperature is higher then the catalytic activity of the metal is practically negligible. Copper is also capable of producing many reductions, though not all, and on account of its cheapness and the ease with which it is obtained from its oxide by reduction at 180° C., it may become of commercial importance. Its activity, however, varies considerably according to its method of preparation. It is the best metal for using in the reduction of aromatic nitro derivatives, because its action is only directed to the NO_2 group, and not to the aromatic nucleus. Nitrobenzene can be thus easily transformed into aniline at 230°; between 300° and 400° C. the reaction is regular and rapid, if hydrogen is in excess, when aniline is obtained pure and in a 98% yield. The behaviour of copper is sometimes quite different from that of nickel; for example, at 300°—330° it converts cyclohexanol into cyclohexanone.

The preparation of chemical substances by the process of Sabatier and Senderens is carried out on the commercial scale by Poulenc Frères, under the direction of Senderens.

The reactions so far described deal with the action of hydrogen in presence of a finely divided metal on a substance in the form of vapour, but many processes have been devised for applying the principle to liquids, as suggested by Ipatieff, Paal, Willstätter, and Skita. The method of Ipatieff consists in heating the substance to be hydrogenated in presence of nickel or its oxide with hydrogen under a pressure of at least 100 atmospheres. The work is described in a series of papers appearing principally in the Journal of the Russian Physical and Chemical Society from 1906 to the present time. On the whole, the results are very similar to those obtained by the method of Sabatier and Senderens, *e.g.*, the aromatic nucleus is hydrogenated in all cases, benzene giving at 250° cyclohexane, which is decomposed at 300° C. into benzene, methane, and hydrogen with deposition of carbon. Acetone and homologues give secondary alcohols, and other examples are summarised in the following table:—

—	Temp.	Pressure in atmospheres.	Product
Phenol	245°	—	Cyclohexanol
Camphor ..	350°	—	Borneol
Limonene ..	300—320°	120	Limonene dihydride
Pinene	265°	—	Pinene dihydride
Carvone ..	280°	120—130	Carvomenthone
Naphthalene	250°	120	Tetra- and deca-hydrides
Anthracene	260—270°	100—125	Tetra-, deca-, and perhydrides

Quinoline, which is only converted into the tetrahydride by Sabatier and Senderens' method, gives almost entirely the decahydride. Oleic acid at 100° C. and under 26 atmospheres pressure does not suffer any appreciable change, but at 60 atmospheres pressure it is converted into stearic acid.

Paal's method.—Many attempts have been made to use metals in the colloidal state as the catalyst in processes of hydrogenation. In presence of certain organic bodies, as proved by Paal, the stability of colloidal metal solutions is considerably increased. The two substances principally used by Paal are called by him protalbinic and lysalbinic acids, and may be prepared from egg albumin (this J., 1902, 996), by heating at 100° C. with 3% aqueous sodium hydroxide for one hour. On acidifying with acetic acid protalbinic acid is precipitated and is purified from salts by dialysis. After washing with alcohol and drying it forms a white powder, easily soluble in aqueous acetone or acetic acid, and in both acids and alkalis. Lysalbinic acid is contained in the mother liquors of protalbinic acid, and is isolated by evaporating to a small bulk, and acidifying with sulphuric acid. It is then purified by pouring its concentrated aqueous solution into alcohol, and is a fine white powder, soluble in water. It constitutes about one-quarter of the original weight of albumin. An alkaline solution of sodium lysalbinate or protalbinate is treated with platinic chloride and a slight excess of hydrazine hydrate and allowed to stand five hours. The salts produced are removed by dialysis, and the solution concentrated, first, on the water bath, and then in a vacuum. The product, when dried at 100° C., forms black glistening scales, which dissolve readily in water to a dark brown opalescent solution. Colloidal solutions of palladium may be prepared in a similar manner (Skita and Meyer, this J., 1913, 46). The solutions are very stable, and even when concentrated can be heated for some time without undergoing change.

An aqueous solution of the colloidal platinum is added to an alcoholic solution of the substance to be hydrogenated, and hydrogen passed in. It is of importance to keep the liquid agitated, and temperature and pressure both exercise an influence on the course of the reaction. (Compare Skita, Ber., 1908, 41, 2938; 1910. 43, 3393.) The results obtained are similar to those produced by Sabatier and Senderens' method, but colloidal palladium will not reduce the benzene nucleus. The reduction of oleic acid to stearic acid was effected by Fokin (this J., 1907, 1149) at the ordinary temperature, using palladium or platinum black. Paal and Roth (this J., 1908, 864) have shown that sodium oleate and colloidal palladium give a 60% yield of pure stearic acid, and, further (this J., 1909, 611), that castor oil, croton oil, olive oil, cotton-seed oil, linseed oil, butter, and lard can be completely reduced by colloidal palladium and hydrogen to give in all cases a hard, white, brittle crystalline substance. In 1911 Skita and Paal patented (Ger. Pat. 230,724) the use of palladous chloride and gum arabic instead of colloidal palladium, and they have proved (Ber., 1911, 44, 2,862) that strychnine in dilute acetic acid containing a little 1% palladium chloride and 1% gum arabic is reduced to strychnine dihydride in presence of hydrogen under two atmospheres pressure, and under three atmospheres to strychnine tetrahydride. Brucine under similar conditions is converted into brucine dihydride.

Willstätter's method.—The researches of Willstätter have made the use of platinum or palladium black in presence of hydrogen of almost general application. The substance to be acted on is dissolved in a suitable solvent, mixed with platinum black (one-third to one-thirtieth of the weight of the substance) and hydrogen led in, during which time the apparatus is shaken continuously. In this manner ethylenic linkages easily become saturated; ethyl oleate is changed to ethyl stearate; eugenol and isoeugenol give propylguaiacol (Fournier, Bull. Soc. Chim., 1910 [4] 7, 23); cholesterol in ethereal solution with one-third of its weight of platinum black is completely changed to cholesterol dihydride in two days (Willstätter and Mayer, this J., 1908, 642, 829). The method gives good results with aromatic hydrocarbons, which are converted into the corresponding cyclohexanes and also with the terpenes.

Platinum would appear to give in general more satisfactory results than palladium.

Synthetic ammonia.

The affinity of nitrogen for hydrogen is so small that the two gases do not unite to any appreciable extent either at ordinary or raised temperature. The best mixture of these gases for the production of ammonia is 1 vol. of nitrogen to 3 vols. of hydrogen, but the limit of the percentage of ammonia attainable under ordinary pressure is at high temperatures very small indeed, as will be seen from the following table :—

Percentage amount of NH_3 *in the equilibrium of the reaction* $N_2+3H_2=2NH_3$.

Temperature.	Pressure in atmospheres.		
	1	100	200
400°	0·48%	—	—
500°	0·13	10·8%	—
550°	0·0769	6·70	11·9%
600°	0·048	4·5	—
650°	0·0321	3·02	5·71
700°	0·021	2·1	—
750°	0·0159	1·54	2·99
800°	0·011	1·1	—
850°	0·0089	0·874	1·68
950°	0·0055	0·542	1·07
1000°	0·0032	—	—

It would, therefore, appear from the figures in the first column of the table that the production of ammonia by this process would be practically impossible. There is, however, another factor of the greatest importance to be considered, for the number of molecules on both sides of the equation

$$\underset{4\text{ mols.}}{N_2+3H_2}=\underset{2\text{ mols.}}{2NH_3}$$

is not the same, and this decrease means that the percentage of ammonia attainable is proportional to the working pressure over a wide range. As will be seen, the values for the percentage equilibrium at 100 and 200 atmospheres show a very different state of affairs, and technical synthesis becomes a possibility if the equilibrium at such pressure can be reached and in a short enough time. The process developed is due to the work of Haber and Le Rossignol (Z. anorg. Chem., **44**, 341 ; Ber., 1907, **40**, 2144 ; Z. Elektrochem., 1908, **14**, 181 ; 1910, **16**, 244 ; Ger. Pats., 235,421, 1908 ; 238,450, 1909 ; Fr. Pats. 406,943 of 1909 ; see also this J., 1905, 131, 545 ; 1910, 485, 488, 1057 ; 1913, 134 ; 1914, 49). Haber has shown that with suitable catalysts it is possible to work at temperatures ranging between 500° and 600° C. and at high pressure, so that the equilibrium is nearly maintained with a high rate of flow of gas. The actual process used by the "Badische Anilin und Soda Fabrik," which firm has taken over the patents, is based on the description given by Haber (see this J., 1913, 134). It consists in compressing a mixture of 1 vol. of nitrogen and 3 vols. of hydrogen in presence of a catalyst, when under a pressure of 175 atmospheres and at a temperature of nearly 550° C. about 8% by vol. of ammonia is formed. The gases pass from the compression cylinder to a cooling arrangement, where the ammonia liquefies, and may be drawn off, or water may be directly introduced into the apparatus, and under the pressure used a concentrated solution of ammonia produced directly. The very high pressure used limits the space which may be filled with the catalyst, but more than 1 kilo. of ammonia can be produced per hour for each litre of catalyser space. The necessary heat is produced by the reaction itself, for 13,000 grm.-calories are set free at this temperature by the formation of 1 grm.-equivalent of ammonia from its elements. Haber describes osmium as the best catalyst but for use on the large scale it cannot be seriously considered, as the world's stock does not amount to much over 100 kilos. and only small amounts are obtained annually. Next in order comes uranium, which, in the form containing carbide, such as is produced in the electric furnace from uranium oxide and carbon, crumbles under high pressure to a very fine powder possessing at 500° C. very high catalytic activity. An essential when using uranium is that no water or substances which would give rise to water should be present in the gases. When this process came to be applied on the large scale, difficulties of quite an unusual nature had to be overcome, more particularly in the construction of apparatus to withstand the necessary pressure and temperature. Steel loses its carbon at the temperatures in question, so that its capability of withstanding pressure is reduced to a minimum. Iron completely changes its properties and at high temperatures becomes, in quite a remarkable degree, pervious to hydrogen under high pressure. But these and many other difficulties have now been completely overcome, and the works of the Badische Company at Oppau, near Ludwigshafen-am-Rhein, are producing large quantities of ammonium sulphate annually. The process is not without danger, as very slight amounts of oxygen or air entering the apparatus are sufficient, at the high pressure, to cause explosions. Automatic devices for indicating the presence of oxygen have been introduced, and the danger from explosion is guarded against by setting up the apparatus in bomb-proof chambers. A very careful study has been made of the various catalysts which can be used, and it has been found that in general they are made more active by the presence of certain foreign substances or promoters ; in many cases a very minute quantity is sufficient to raise the catalytic activity very considerably. Among the more important promoters are the oxides, hydroxides, and salts of the alkali metals and of the metals of the alkaline earths. Moreover, osmium and uranium are not by any means the only possible catalysts, for iron itself, manganese, or tungsten can be used with good effect. Another factor of great importance is the recognition of certain specific poisons for ammonia catalysts. The most active poisons are sulphur, selenium, tellurium, phosphorus, arsenic, boron, or the hydrides of these elements ; also many organic compounds and certain metals of low melting point, which can easily be formed from their compounds by reduction with hydrogen ; for example, lead, bismuth, and tin. Extremely minute quantities of oxygen-sulphur compounds, such as sulphur dioxide, which are almost always present in the purest commercial products or in the so-called pure gases, suffice to render the catalysts absolutely inactive or to diminish their activity very considerably ; thus iron prepared from its oxide with a content of 0·01% Na_2SO_4 or containing 0·1%S is quite useless. The recognition of these facts necessitates the preparation of contact materials free from such poisons, and also the very careful purification of the gases which are to be used. As little as one part per million of sulphur in the gas mixture can be injurious, so that even electrolytic hydrogen has to be further purified. The nitrogen is prepared by the Linde method, or by passing air over heated copper, and the hydrogen by any of the methods already alluded to. In order to free hydrogen from traces of carbon monoxide treatment with caustic alkalis at high temperatures is especially recommended (Badische, Fr. Pat. 439,262 of 1912 ; this J., 1912, 722) ; for instance, hydrogen containing 1% CO can be treated with (A) 80% caustic soda at 260° under 50 atmospheres pressure or (B) 25% caustic soda at 240° C. under 200 atmospheres pressure. Great as the possibilities of this process seem to be, neither the Chilian nitrate nor Norwegian nitrate industries are likely to suffer thereby, for the annual increase in demand for these substances is calculated to amount to 185,000 tons of ammonium sulphate.

The hardening of fats.

The hardening of fats consists in adding to the glyceride of an unsaturated acid the necessary number of atoms of hydrogen to convert it into the glyceride of a saturated acid.

Though by weight the amount of hydrogen required for converting an oil into a workable solid fat is not great, the volume of hydrogen assumes enormous proportions. One ton of oleic acid requires roughly 79,000 litres or 2800 cubic feet, and one ton of triolein requires 75,900 litres or 2680 cubic feet of hydrogen. It has not been found possible to obtain any accurate idea of the amount of oils which are thus treated annually, but it may be mentioned that the Linde Company's method for the production of hydrogen (this J., 1911, 746, 893) is being carried out in various factories for fat hardening to the extent of 1000 cubic metres per hour, which amount is sufficient to harden 100,000 tons of fat annually. There is further a factory in Norway capable of producing 4500 cubic metres of hydrogen by an electrolytic method, and of hardening 150 tons of whale oil every twenty-four hours (Offerdahl, see later). The reason why the hardening of fats has assumed such large proportions is that so much of the natural supply of hard fats is now employed in the making of margarine and other foodstuffs, that the amount of such fats available for soap boiling has been considerably encroached upon, and hence it has become necessary to find other sources of hard fats for the latter purpose. One of the principal oils submitted to the process of hardening is whale oil, of which the world's supply in 1912 amounted to 1,200,000 barrels (about 42,000 tons), more than half of which was obtained from Norway (Offerdahl, this J., 1914, 32) Ten or fifteen years ago only small amounts of whale oil were used in the tanning industry or for lubricating, its taste and smell prohibiting its employment for other purposes. More recently larger quantities have been worked up for the isolation of glycerol. The oil is now almost entirely hardened to a substance melting between 40° and 50° C., which possesses neither taste nor smell.

Although in the application of Sabatier and Senderens' reaction, substances are only used in the state of vapour, and these authors lay stress on the point that the catalyst should not be allowed to become moistened with the substance under treatment, the present methods for the hardening of oils are the direct outcome of the researches of Sabatier and Senderens. The first patent dealing with the hydrogenation of oils in the liquid form was taken out by Normann (Eng. Pat. 1515, 1903; this J., 1904, 26). This patent marks the commencement of a new industry, but, in view of more recent work, it does not appear to contain many of the essentials of success, some of which are :—1. The preparation of the catalyst in a suitable condition. 2. The proportion of the catalyst used. 3. The temperature at which hydrogenation is carried out. 4. The refining of the fatty body. 5. The application of continuous mechanical agitation. 6. The use of hydrogen free from hydrogen sulphide, 0·1% of this gas being sufficient to stop the reaction. The importance of some of these points is illustrated by the following records of experiments by O. Hehner :—

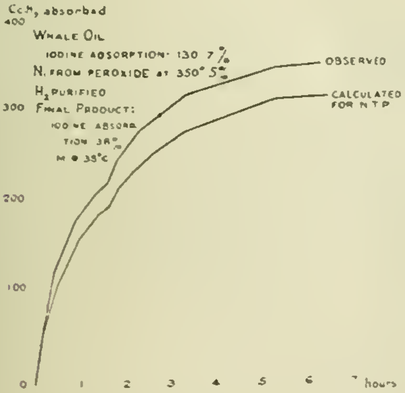

FIG. 1.

Figs. 1 and 2 show the behaviour of whale oil and rape oil respectively when submitted to the action of hydrogen in presence of reduced nickel. The time during which the experiment lasted and the volume of hydrogen absorbed are indicated in these and following diagrams. It will be seen that the iodine value of the whale oil fell from 130·7 to 38, and the melting-point of the resulting solid was 38° C. With the rape oil the iodine absorption fell from 105·4 to 8·3, and the melting-point of the resulting solid was 57° C. Figs. 3 and 4 illustrate the necessity of exercising care in the preparation of the catalyst. Nickel prepared from the hydroxide or from the nitrate, through the oxide, was of approximately equal effect with whale oil at 250°, though much less active in the latter case at 180° C., whereas nickel prepared by strongly heating the nitrate and reducing the resulting oxide was practically without effect on linseed oil, and nickel obtained from the sulphate through the hydroxide (probably containing traces of sulphur) was markedly less active than carefully purified nickel from the hydroxide. The following example, taken

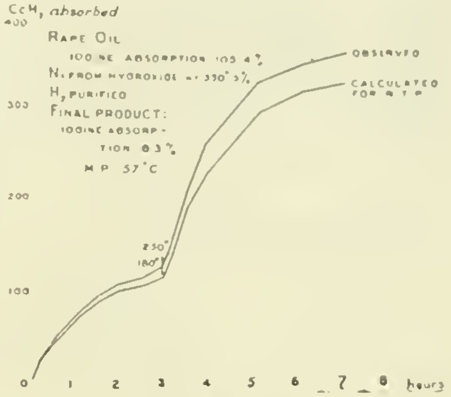

FIG. 2.

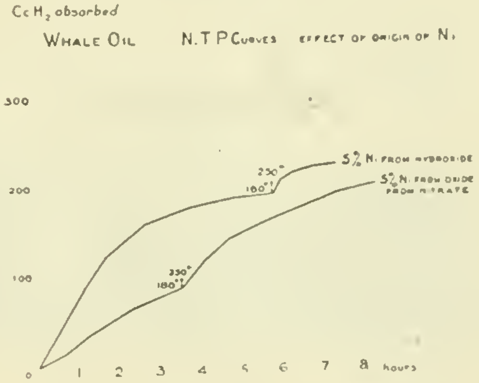

FIG. 3.

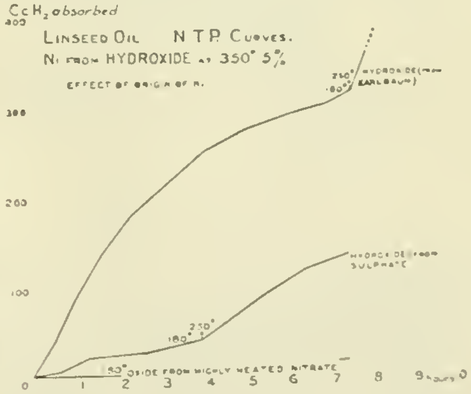

FIG. 4.

along with some other data here quoted, from evidence handed into court in the case of Joseph Crosfield and Sons, Limited, v. Technico-Chemical Laboratories, Limited, may be cited in further exemplification of this point. The iodine value of an oil was decreased from 108·4 to 72·1 by treatment with hydrogen in presence of nickel obtained by igniting nickel carbonate at 400°—450°, and reducing the resulting oxide with hydrogen at 400° C. A specimen of the same oil had its iodine value lowered to 13·2 when treated in presence of nickel prepared from the carbonate by roasting at 300° for 5—6 minutes, and reducing the resulting oxide with hydrogen at 300° C. for 4—5 minutes.

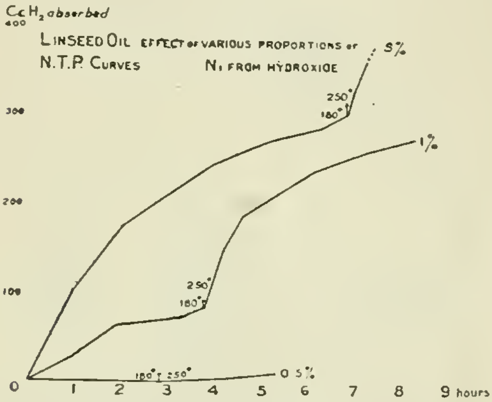

Fig. 5.

The curves in Fig. 5 show the great importance of selecting a definite proportion of the catalyst, and also, in common with most of the previous curves, the effect of temperature on the absorption of hydrogen. With 0·5% of nickel there was practically no absorption of hydrogen, even on raising the temperature to 250°; with 1% of nickel absorption was slow at 180°, increasing rapidly on raising the temperature to 250°, whereas with 5% of nickel.

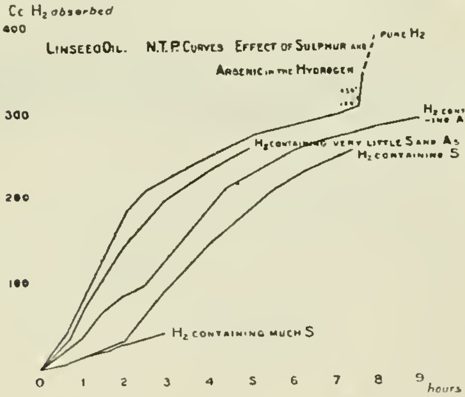

Fig. 6.

the absorption was at the end of seven and a half hours considerably greater at 180° than it was at 250° C., when using only 1% of nickel. Figs. 6 and 7 show the effects produced by the presence of arsenic and sulphur in the hydrogen or by using commercial gases, such as water-gas. By unpurified hydrogen is meant the gas such as would be obtained from a good specimen of zinc without further removal of impurities. Hydrogen containing arsenic was generated from an ordinary sample of zinc. Hydrogen containing much sulphur refers to the gas passed through a very dilute solution of hydrogen sulphide in water. The effect of hydrogenation on a variety of acids and oils is well illustrated by the figures contained in the following table, comprising the results of numerous experiments conducted by F. W. Passmore.

Despite the large amount of work which has been done on the hardening of fats, the literature on the subject is very meagre, and almost the only information which is forthcoming is in numerous patents.* A good, though brief description of many of the processes and forms of apparatus employed is to be found in a paper by C. Ellis (this J., 1912, 1155). There is, however, one patent (Lessing, Eng. Pat. 18,998 of 1912; this J., 1913, 917) not mentioned in Ellis's paper, which appears to differ materially from others, more particularly in the novel method for bringing catalyst and oil in contact. According to this process hydrogen containing 5—10% of carbon monoxide, such as may easily be prepared from water-gas or the thermal decomposition of coal gas or hydrocarbons, is passed over reduced nickel, with formation of nickel carbonyl. The nickel need not be pure, but in the form of such complex mixtures as are obtained in the treatment and reduction of nickel ores. The mixture of hydrogen and any desired proportion of nickel carbonyl is then passed into the substance to be hydrogenated at a temperature between 200°—240° C., when the nickel carbonyl is decomposed and elementary nickel, in a very pure and particularly active form, is produced. The proportion of nickel carbonyl required is very small, excellent results having been obtained with an amount equivalent to 0·1 part of nickel per 100 parts of oil. Fresh nickel carbonyl is always passing into the substance to be hydrogenated, and the nickel is believed to act in the nascent condition at the moment of decomposition of the nickel carbonyl. This seems to be borne out by the fact that if the same percentage of nickel be introduced into an oil as nickel carbonyl, the latter decomposed and then hydrogen passed in, there is practically no result from the commercial point of view. (Compare C. Ellis, *loc. cit.*; Shukoff's Ger. Pat., 241,823 of 1910.)

German Patents.—256,500 and 260,885, 1911.

French Patents.—378,528, 1907; 426,343, 1910; 425,729 and 433,294, 1911; 439,262, 441,097, 447,420, 447,688, 449,668, and 450,703, 1912; 458,445, 1913.

U.S. Patents.—1,004,034 and 1,004,035, 1911; 1,040,531, 1,040,532, and 1,043,580, 1912: 1,058,738, 1,059,720, and 1,060,673, 1913. (See this J., 1904, 26; 1907, 1150; 1908, 296; 1909, 1005; 1910, 1396; 1911, 966, 1022, 1266, 1461; 1912, 139, 398, 443, 722, 826, 1085, 1186; 1913, 234, 253, 475, 497, 543. 610, 612, 705, 797, 798, 917, 958, 989, 1119.)

The process of hydrogenation gives rise to fats of any desired degree of hardness, which are used at the present time primarily for soap making. It is stated that the soaps produced are very hard and do not lather well, but this objection would not appear to be of a very serious nature, as the hardened fat could be mixed with a suitable quantity of another fat, which would give the desired quality to the resulting soap. Hardened fish oil is odourless and gives a good soap, but unless the iodine value of the oil has been lowered during hydrogenation to 50 or less, then, on ironing materials washed with such soap, the odour of fish oil again becomes noticeable. Hardened oils seem likely to be used largely in the future for lubricating purposes, and as foodstuffs. Even at the present time hardened cottonseed oil, a substance resembling lard, is used edibly, and a great number of physiological experiments carried out on the edible properties of hardened whale oil (Offerdahl, *loc. cit.*) have proved it to be easily digested. One point, however, will require very careful consideration in this respect, namely, that an oil hardened by a process including nickel as catalyst always contains small amounts of nickel. Offerdahl has shown that the average amount of nickel in hardened whale oil is from 0·5—2 mgrms. per kilo., whilst the most found was 4 mgrms. per kilo. Despite the facts that 99·8% of nickel taken is eliminated from the system, and that Normann and Hügel (*Halbmonatsschrift für Margarin-industrie*, 1913, VI., No. 17) have shown that this amount of nickel is very much less than that contained in many foodstuffs, prepared in nickel vessels, which have had no injurious effects on those who have eaten them, the matter is one which will require detailed attention.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL PLANT; MACHINERY.

Patents.

Smoke and like particles in air or gases; Treatment of ——. G. B. Burnside and J. S. Anderson, Glasgow. Eng. Pat. 23,605, Oct. 18, 1913.

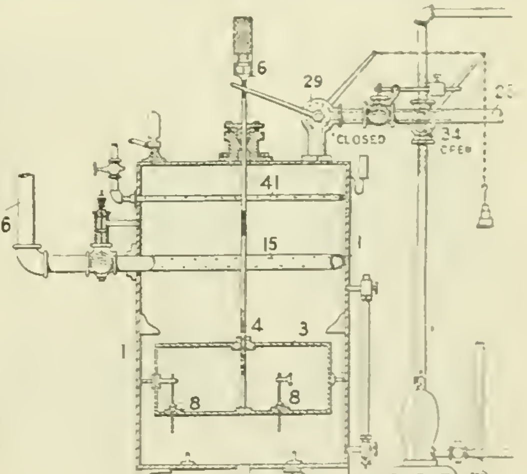
The particles are caused to coalesce and condense by treating the gases with moist steam which has been electrified by passage through a fine jet.—W. H. C.

Sizing and classifying comminuted materials; Process and apparatus for ——. H. M. Sutton and W. L. and E. G. Steele, Dallas, Tex. U.S. Pat. 1,114,935, Oct. 27, 1914; date of appl., Jan. 22, 1914.

The materials are fed upon a continually moving, transversely inclined belt, having a roughened surface. A vibratory motion is imparted to the belt from below, the frequency of the impulses increasing from the feed point onwards, thus causing the particles to diverge from their normal path at increasingly greater angles according to their dimensions. The products of different sizes fall into separate receptacles.—W. H. C.

Evaporating-accelerator. E. C. Dun, Santiago, Cuba. U.S. Pat. 1,110,752, Sept. 15, 1914; date of appl., May 3, 1911.

The condensed water and air from the heating chamber of the evaporator enter the receiver, 1, through the pipes, 16, 15, and the water accumulating at the bottom of the receiver causes the float, 3, to rise, closing the valve, 29, and opening the steam valve, 34. Steam enters the pump, 22, which commences to pump the water out of the receiver. When the float sinks to the bottom of the receiver, the valve, 29, connected by way of pipe, 26, with a vacuum pump, is opened and the steam valve, 34, is shut. The vacuum pump, withdraws the air from the receiver and some air from the external atmosphere enters the float through the valve, 6, and the hollow shaft, 4, and drives out any water that may have entered the float through the valves, 8. If any steam enters the vessel, 1, it may be condensed by a spray of cold water from the pipe, 41.—W. H. C.



Filter-leaf. N. A. Burgess, New York, Assignor to Butters Patent Vacuum Filter Co., Inc. U.S. Pat. 1,114,224, Oct. 20, 1914; date of appl., Aug. 30, 1913.

A horizontal pipe fitted to the filter-leaf has an opening protected by an overlapping lip beneath the surface of the filter-cake.—W. H. C.

Separating apparatus. P. Kropp. Fr. Pat. 469,073, Feb. 20, 1914. Under Int. Conv., Feb. 21, 1913.

Solid particles suspended in a liquid are removed by imparting to the latter a motion similar to that of a breaking wave by means of appropriate baffles.—W. H. C.

Absorption and decoloration; Method of effecting ——. G. H. Hellsing, Trollhättan, Sweden. Eng. Pat. 22,063, Sept. 30, 1913.

See Ger. Pat. 276,343 of 1913; this J., 1914, 1083.—T.F.B.

Driers; Continuous automatic centrifugal ——. C. A. Wendell, Joliet, Ill., U.S.A. Eng. Pat. 4808, Feb. 24, 1914.

See U.S. Pat. 1,088,754 of 1914; this J., 1914, 631.—T.F.B.

Separator; Centrifugal ——. W. Mauss, Johannesburg, Transvaal. U.S. Pat. 1,115,852, Nov. 3, 1914. Date of appl., March 25, 1913.

See Eng. Pat. 6478 of 1913; this J., 1913, 858.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Explosions in Mines Committee; Sixth report of the ——. [Cd. 7638.] 17 pp. (See also this J., 1913, 476, 688, 1148.)

Firedamp in the air helps the inflammation of coal dust, but it does not appreciably diminish the protective effect of an admixture of fine uninflammable dust, 50% of which should pass a 200-mesh sieve. Water spraying must be uniform; an atomiser is best. To prevent propagation of flame from coal-dust when a 24-oz. charge of powder is fired into it, 30% of water is required, and 50% in the case of the cannon and 5 lb. of coal dust, or coal gas and air through 150 ft. of the 3-foot gallery. Reduction of the oxygen to 17% would not prevent explosion, and would be harmful to the miners. Home Office recommendations are: (i) 50% of non-inflammable dust (pulverised argillaceous shale is recommended), or (ii) 30% of water in the dust throughout the roads, or (iii) a combination of these.—O. E. M.

Acetylene; Quantity of —— necessary to cause an explosion in a closed space. Bosnische Elektricitäts-A.-G. Z. Bayr. Rev.-Vereins, 1909, Nr. 6. J. Gasbeleucht., 1914, 57, 65.

A mixture of acetylene and air will not explode if the proportion of acetylene is less than 2·5%. The experiments were carried out in a large chamber of 11 cb. m. capacity, ignition being effected by a flame. There is no danger of explosion in dwelling houses, etc., having rooms with over 40 cb. m. air space, if the charge of carbide does not exceed 2 kilos.—A. T. L.

Carbonisation results with coal stored in the open and in bunkers. K. Bunte. J. Gasbeleucht., 1914, 57, 450.

Tests were made at the Karlsruhe experimental gas works with the same coal, part of which had been stored in the open air for 3½ years to a height of 3·5 metres, and part in bunkers to a height of 3 metres. The results showed that so far as gasification was concerned there was practically no difference effected by the method of storage, but that the coke from the coal stored in the open was much smaller and more friable.—J. H. J.

Coke-oven gas; Long-distance transmission of ——. R. Witzeck. J. Gasbeleucht., 1914, 57, 361—368, 389—392.

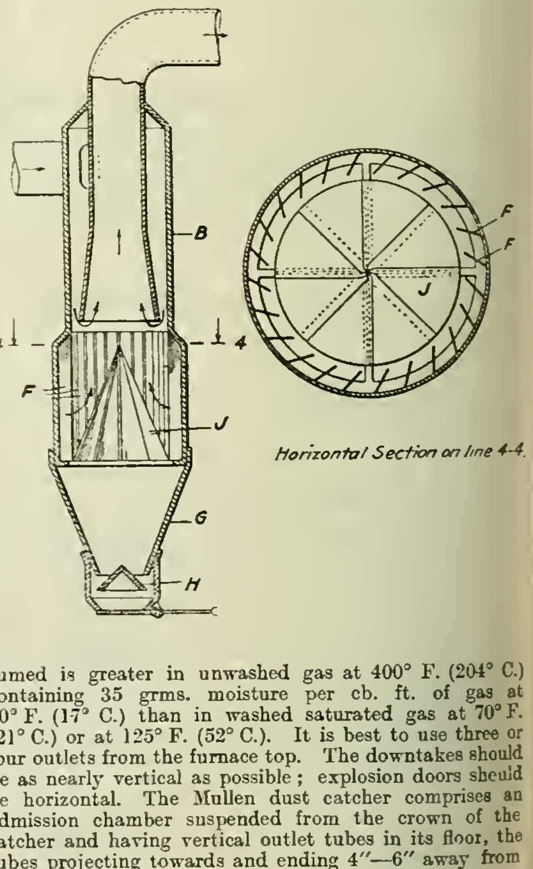
The history of the coke oven and its development into the modern regenerative form, with by-product recovery, are discussed. It is shown that there are advantages in manufacturing in a large oven, situated in a coalfield, and distributing through considerable lengths of pipe, over manufacturing on the small scale near the consumer. Examples of modern installations are described in detail. —O. E. M.

Producer gas; The Hilger rotating grate generator for ——. V. O. Keller. J. Gasbeleucht., 1914, 57, 80—82.

The roof of the generator is provided with a hopper for admitting the charge, and a lock chamber, so as to seal the interior of the furnace from the air during the feeding. The hearth of the furnace has the form of an inverted bowl which can be rotated by means of worm gear. The rotating bowl contains the grate which is composed of two parts. On the lower part there is a star-shaped hood. A star-shaped opening leads from here to the top of the grate, and permits the air and steam mixture to be admitted to the furnace. By means of a simple mechanism, the cogged wheel which drives the hearth can be engaged by worm wheels on either side. The direction of rotation can thus be reversed and a tilting motion imparted to the ash basin. The consumption of fuel is more thorough with this than with other generators.—J. N. P.

Blast-furnace gas; Cleaning and utilisation of ——. J. E. Johnson, jun. Met. and Chem. Eng., 1914, 12, 685—692.

When the gases contain a large amount of water vapour some may be removed even by wet scrubbing. The total heat available per lb. of dry fuel gas consumed is greater in unwashed gas at 400° F. (204° C.) containing 35 grms. moisture per cb. ft. of gas at 60° F. (17° C.) than in washed saturated gas at 70° F. (21° C.) or at 125° F. (52° C.). It is best to use three or four outlets from the furnace top. The downtakes should be as nearly vertical as possible; explosion doors should be horizontal. The Mullen dust catcher comprises an admission chamber suspended from the crown of the catcher and having vertical outlet tubes in its floor, the tubes projecting towards and ending 4″—6″ away from the surface of water maintained in continuous flow by a supply pipe at the centre of an inverted cone-shaped water container. The gases pass through an annular chamber surrounding the admission chamber to the outlet. In the Brassert-Witting primary dry cleaner, used after the ordinary centrifugal dust chamber, the gases enter tangentially an annular chamber, B, the lower end of the outlet being flared. Below the outlet the chamber is larger and contains side baffles, F, and a central conical baffle, J. A cone, H, is placed at the bottom of the conical dust collector, G. In a modification the end of the outlet is barrel-shaped, a spiral deflector is placed in the annular



chamber, B, and an annular chamber is formed outside the baffles, F, which have vertical spaces between them. In another modification bars on the outer wall of the chamber, B, and extending above and below the flared end of the outlet, replace the baffles, F, and cone, J.

—W. F. B.

Coal gas residuals. F. H. Wagner. Met. and Chem. Eng., 1914, 12, 696—702.

The following results have been obtained with the Feld hot tar washing process (see Eng. Pats. 20,139 of 1907 and 9086 of 1910; this J., 1908, 1011; 1910, 999).

Washing without Pelouze condenser.

Gas temperature at inlet to washer.	Tar content in grains per cb. ft.		Grains removed	Efficiency, %	Gas passed per 24 hrs., cb. ft.
	Inlet.	Outlet.			
131° F.(55° C.)	11·512	0·2930	11·219	97·46	2,463,000
127° F.(53° C.)	10·386	0·2160	10·170	97·92	2,453,832
129° F.(54° C.)	10·818	0·2930	10·525	97·29	2,341,800
129° F.(54° C.)	13·518	0·4170	13·101	96·92	2,397,000
126° F.(52° C.)	9·907	0·5250	9·382	94·70	2,400,000
Washer with Pelouze condenser.					
140° F (60° C.)	10·050	0·0436	10·0064	99·56	2,600,000
194° F.(90° C.)	13·100	0·0872	13·0128	99·34	2,600,000

With the Feld system of ammonia extraction (see this J., 1912, 430 and 1911, 1381) combined with the Bueb process for the extraction of cyanogen (this J., 1903, 204) a plant carbonising 300 tons of coal per day, working 250 days per year, gave the following results :—

Cyanogen	1147 cwt. at £3 2s.	£3556
Sulphate	12,047 cwt. at 14s.	£8433
NH_3 in press cake	266 cwt. at 32s. 6d.	£432
Total gross earnings		£12,421

The working expenses were :—

Materials	£770
Steam	£346
Power	£560
Miscellaneous	£208
Labour	£521

Total working expenses	£2405
Net earnings per year less interest and depreciation	£10,016

—W. F. B.

Tar: Electrical removal of —— from gas. F. W. Steere. J. Gas Lighting, 1914, **128**, 309—311. (See also this J., 1914, 1000.)

When crude coal-gas or producer gas is submitted to an alternating high-tension discharge at 40,000—80,000 volts in an ioniser, the tar fog condenses to large globules, which can be readily removed by a centrifugal or by a Pelouze and Audouin extractor. In an experimental apparatus treating 30,000 cb. ft. of gas per hour, rich coal-gas given off during the earlier part of the coking period was passed through a washer-cooler and then through the ioniser. The best temperature was 65°—80° C. (149°—176° F.). The naphthalene was separated in crystalline form by passing the tar-free warm gases from the tar-extractor through a washer-cooler, and the cooled gas contained only sufficient naphthalene vapour for saturation at the temperature of the gas. The separated tar contained little benzene and toluene, a larger proportion of these constituents remaining in the gas and increasing its illuminating power. This effect was increased by raising the temperature at which the gas entered the ioniser. The process has been used continuously since January for removing tar from producer gas for use in engines.

—A. T. L.

Gas and water mains; Corrosive action of electrical currents on the —— in the town of Gablenz a. N. (Austria). T. Herrmann. J. Gasbeleucht., 1914, 57, 88—89.

Attention is drawn to the serious electrolytic corrosion of water and gas mains in Gablenz. The origin of the earth currents is attributed to the electric tramways in the streets. These vagrant currents are assisted by impurities introduced into the soil through acids formerly discharged by factories in various places. The damaged pipes are for the most part situated under the tram rails, and cast and wrought iron tubes were equally attacked. In a large number of lead pipes, the metal was transformed into a brown powder, whereby serious leaks of gas occurred. The accumulation of gas led in one instance to a disastrous explosion. Especial damage has been caused at the gas works where many lines converge, through stray currents travelling along the main pipes connected with the plant. The water conduits and oil pumps were thus destroyed. Accidents also arose from the difference in potential existing between the earthed gas plant and the tram rails, which led to discharges between the two. In addition to electrolytic actions, a number of accidents have arisen through lightning discharges. These have struck the overhead live wires, or in some cases exposed metal fittings, and created a short circuit between the electrical leads and the gas mains or telephone wires. The disturbances at the gas works have been obviated by suspending electrical traction altogether and by interrupting the metallic connection between the street mains and the gas works. This has been effected by the use of flanged joints between the pipes, packed with layers of mica. This method however has introduced an additional danger on account of lightning discharges. Electrical charges concentrated in the ground surrounding the works tend to pass along the whole length of pipes as offering the path of least resistance to distribution in the earth; currents thus tend to leap over the insulated section and cause dangerous discharges at the metallic termini. The parasitic earth currents arise from the difference in potential—in some cases amounting to 20 volts—between the tram rails and adjacent pipes, and these can best be minimised by lowering this potential. It is desirable therefore to increase the conductivity of the rails. Short circuits by lightning discharges can be obviated by more carefully arranged installations.—J. N. P.

Petroleum; Notes on the composition of Mid-Continental (U.S.A.) ——. F. W. Bushong. J. Ind. Eng. Chem., 1914, 6, 888—890.

The results of repeated fractional distillations of a sample of Oklahoma petroleum are given. The crude oil had the sp. gr. 0·8513 at 15°/15° C. (the original oil at the well was lighter, some gasoline being lost during transport). The total gasoline fractions (b. pt. up to 150° C., sp. gr. 0·6296—0·7687, n_D^{15}=1·3616—1·4300) amounted to 13·77% and the kerosene fractions (b. pt. 150°—300° C., sp. gr. 0·7715 0·8530, n_D^{15}=1·4320—1·4760) to 28·80% by vol. The fraction of b. pt. 296°—298° C. yielded 10% of a red ozonide (compare Molinari and Fenaroli, this J., 1908, 1146) of which a portion purified by dissolving in ether had the composition, $C_{17}H_{20}O_6$. The fraction of b. pt. 252°—254° C. was refined by treatment with liquid sulphur dioxide (Edeleanu, this J., 1910 143; 1914, 343); the oil recovered from the sulphur dioxide extract yielded a nearly white ozonide which after being purified by washing its ethereal solution with potassium hydroxide had the composition $C_{15}H_{16}O_3$. The reaction of unsaturated hydrocarbons with ozone is considered to be a valuable means of detecting new constituents of petroleum, which constituents can be extracted from the oil by means of liquid sulphur dioxide.

—A. S.

Viscosimeters [for mineral oils]; Comparison of Engler's and Barbey's ——. C. Baheux. Les Matières Grasses, 1913, 6, 3221—3224. Petroleum, 1913, 9, 161—162.

Barbey's ixometer measures the fluidity of an oil, but does not give information of the behaviour of a lubricating oil in practice. In the case of machine oils, whose fluidity is usually determined at 35° and 50° C., the results are concordant, but for testing cylinder oils (100° C.) Engler's viscosimeter is preferable, since less time is required. Moreover, the use of an oil-bath with the ixometer involves a considerable error due to the irregular distribution of the heat, whereas the heating bath of Engler's apparatus is easily regulated. The values obtained with the two apparatus do not agree in all cases, the friction coefficient being greater in the case of Barbey's apparatus, which has a much longer outlet tube. Of two oils with equal viscosity that with the smaller friction coefficient will pass more rapidly through the outlet tube of Barbey's apparatus than the other. This is particularly noticeable with compound oils, the friction coefficient of which is lower than that of mineral oils of equal viscosity. Only mineral oils of the same viscosity that have been refined, etc., in the same way can be compared by means of Barbey's apparatus. Engler degrees may be calculated into Barbey degrees by the formula :—

$$f=\frac{720{,}000,}{v.a.m.}$$

where f represents the Barbey fluidity degree, v the Engler viscosity, a the efflux velocity (seconds in Engler's viscosimeter) of 200 c.c. of water at 20° C. and m a factor varying with the temperature and the quality of the oils. The results agree well in the case of mineral oils at 50° and 100° C., but are not applicable without correction to oils tested at 35° C., or to compound oils.—C. A. M.

Mineral oils ; Use of the Kubierschky column in the distillation of ——. E. Graefe. Petroleum, 1913, 9, 303—307.

Kubierschky's fractionating column consists of superposed chambers having the construction shown in Fig. 1. It has given excellent results in the manufacture of bromine, and has now been adapted to the distillation of mineral oils, in a series of two or four (Fig. 2). The crude oil from the reservoir, F, is heated in G by vapours from the column II, the heaviest fraction of these vapours being simultaneously condensed. The condensed portion falls into the cooler, K, which is charged with water, and thence into D_2, where it is separated from the water. The heated oil from G is passed into the column I, where it meets an ascending current of steam, and is freed from its lighter fractions. It then falls into the vessel, D_1, whence, after separation of water, it is pumped by the pump, E, into the heater, H, and is heated to a higher temperature by the vapours from II. It then passes into II and is freed from lamp oil fractions by superheated steam, whilst the residue is drawn off at N. If further fractionation is required a third or fourth column is added to the apparatus. For the distillation of lubricating oils the steam from the superheater, M, must have an initial temperature of not less than 550° C., and, to prevent condensation of oil, must not cool below about 300° C. For the recovery of the steam the vapours leaving the column are passed into the heater, G, where the temperature falls to 100° to 150° C. and the lubricating oil is condensed and drawn off into K. Part of the steam is conducted into the column I and used for distilling light fractions from another oil, whilst the remainder is brought back to the superheater, M, and again heated to 550° C. In the distillation of crude benzine about 5% of b. pt. up to 150° C. is separated in I, whilst the remainder is heated in II to obtain a product boiling exactly at 150° C., and a residue (4%) of b. pt. up to 225° C. One part of steam is required for each part of distillate. In the case of oils containing asphaltum the temperature need not exceed 250° to 280° C., and a good quality of asphaltum is obtained, whilst there is only slight decomposition of sulphur compounds. Petroleum residues containing paraffin wax are readily fractionated into a semi-solid distillate and a hard undecomposed amorphous wax. It is essential, however, that the lower parts of the columns should be well insulated to prevent loss of heat.—C. A. M.

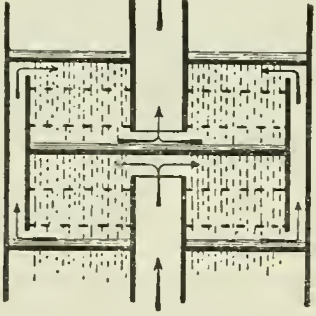


Fig. 1.

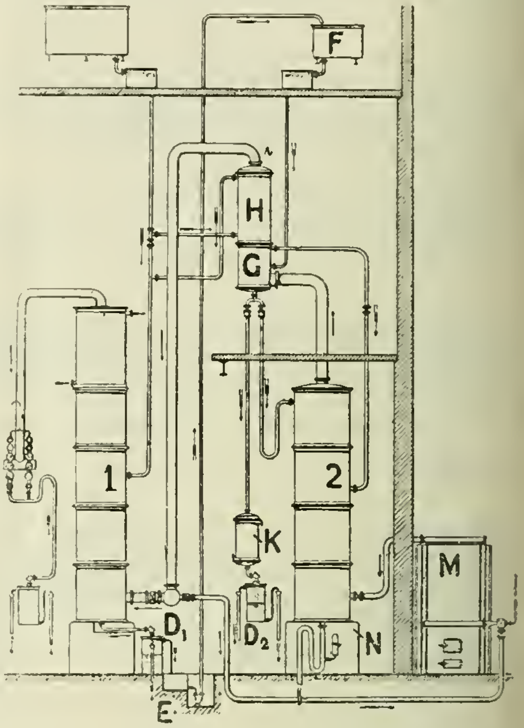

Fig. 2.

Motor fuel ; Peroxidised kerosene as ——. G. B. Selden. Petroleum, 1914, 9, 1304—1305.

Kerosene and other heavy petroleum oils can be utilised as fuel for internal combustion engines if small quantities of peroxides or other highly oxygenated substances, such as picric acid or nitronapthalenes, etc., are either dissolved in them or sprayed into the air inlet of the carburetter. Thus petroleum with 3% of hydrogen peroxide is stated to be perfectly stable, to differ from the original oil but little in either colour, specific gravity, or flash point, and to burn perfectly clean and without residue in the cylinder or odour in the exhaust. The power of the engine is moreover increased. Although aqueous peroxide may be used as a spray, it is preferable to shake the aqueous peroxide with the oil, and allow to separate. The hydrocarbon layer will then contain most of the hydrogen peroxide, and is decanted off. Many nitrated substances have also been employed in amount varying from 0·5 to 5% in solution in the oil, with similar results. It is claimed for example that an addition of 2% of naphthalene picrate increased the power of the engine by more than 100%. Similar nitrated compounds of naphthalene, phenanthrene, pyrene, and picene have also been used.—G. F. M.

Heavy oils (tar, tar-oil) ; Use of —— *in internal-combustion engines.* F. Drexler. Oelmotor, 1913, 2, 125—137, 309—315, 433—437, 563—575. Chem.-Techn. Rep., 1914, **38**, 358.

Regular ignition and complete combustion of crude tar and heavy oils are difficult to obtain in a Diesel engine on account of the varying quality of the fuel. A more rational method of using tar as fuel for engines is by the production of oil-gas from the tar, and of carbon monoxide from the non-volatile residue, the mixed gases being used in a gas-engine.—A. T. L.

Benzine; Electrification of ——. F. Dolezalek. Chem.-Ind., 1913, [6]. Petroleum, 1913, 9, 24—25.

Electrification of benzine passing through a pipe is intensified when the pipe is connected with the earth owing to the removal of the electricity from the pipe. Connection of a benzine tank with the earth is thus no safeguard against electrification of the liquid, and is also superfluous, since in practice tanks are not sufficiently insulated to retain electrostatic charges. The increase in electrification when air and benzine are forced together through a pipe is due to the greater friction produced. The igniting capacity of a spark depends upon the heat generated, and this depends upon the potential difference and the quantity of electricity. For the production of a spark at least 300 volts are required, but such a spark only causes ignition when a sufficient quantity of electricity is present; on the other hand a spark produced by 10,000 volts will not cause ignition when the amount of electricity is very small. The very slight, barely perceptible sparks given by electrified benzine have only slight igniting power, since only small quantities of electricity can accumulate owing to the poor conductivity of the liquid; yet such sparks may cause ignition when they meet fine conductive particles. The addition of soap to benzine, as suggested by Richter, is useless as a protection. (See also this J., 1913, 128.)—C. A. M.

Benzine from natural gas. Z. Biluchowski and S. v. Pilat. Petroleum, 1914, 9, 1305.

The natural gas obtained from the oil wells of Galicia contains considerable quantities of benzine. Gases of sp. gr. 0·820 to 0·892, after drying with calcium chloride, were led through three well-cooled vessels, connected together in series, containing benzine or kerosene. The issuing gas was specifically lighter and had given up from 3·6 to 9·6% of benzine vapours. The benzine obtained from the naphtha contained 30 to 56% more aromatic hydrocarbons than a similar benzine obtained from the natural gas by condensation, and it is consequently concluded that benzine can be most advantageously obtained from the gas by absorption. The heating value of the natural gas only falls by this process from 9132 to 8856 calories.—G. F. M.

Mineral oils; Detection of rosin oil in ——. Nachr. f. d. Zollstellen, 1914, 139—140. Chem.-Techn. Rep., 1914, 38, 363.

Aniline dyes are sometimes added to mineral lubricating oils in order to destroy fluorescence. Before testing such oils for rosin oil the dye should be extracted by shaking the oil repeatedly with strong hydrochloric acid, and then washing with water. Viscous oils should be diluted with ether to facilitate the extraction; the ether being afterwards evaporated.—A. T. L.

Paraffin wax in mineral oils; Determination of ——. F. Schwarz and H. von Huber. Chem. Rev. Fett Ind., 1913, 242—244. Petroleum, 1913, 9, 235—236.

From 1 to 5 grms. of distillate (or less of crude wax) are dissolved in the smallest possible quantity of a mixture of butanone (methyl-ethyl-ketone) and water (sp. gr. of mixture 0·812 at 20° C.) (see this J., 1912, 62), the solution cooled to —20° C., and sufficient butanone added to keep the oil in solution. The precipitate is collected on a filter chilled by a freezing mixture, and is washed with butanone (sp. gr. 0·812) at below —15° C., with constant stirring, until free from oil, and then dissolved in petroleum spirit, the solvent evaporated, and the residue weighed. In some cases slightly more paraffin wax was found by this method than by treatment with alcohol-ether, but oils freed from wax by means of butanone never gave a precipitate with ether-alcohol. For quantities of wax below 13% the results agreed with theory within 0·4% (usually 0·1 to 0·2%).—C. A. M.

Asphaltic material; Determination of —— in petroleum by the so-called excise method. L. Gurwitsch. Petroleum, 1914, 9, 1303—1304.

The determination of asphaltum in petroleum products as carried out by the Russian excise authorities consists in shaking 50 c.c., diluted with 100 c.c. of benzine, with 10 c.c. of sulphuric acid of sp. gr. 1·84, and after standing, reading off the volume of separated asphaltic material. Experiments show that in the case of lubricating and vacuum oils, not only is the indicated percentage of asphaltum in some cases too high owing to benzine being carried down with it, but also a considerable quantity of pure oil may be held in solution in this benzine. In an actual test where 56% of asphaltum was indicated, only 9·5% was present, the difference being benzine and pure oil. On the other hand with a cylinder oil known as viscosine, 13% of asphaltum was indicated by the test, but when this same oil had been concentrated, but not further refined, so that the residue then contained a still larger proportion of asphaltum, the excise test gave a zero value. In some cases, in fact, a negative percentage of asphaltum may be indicated owing to absorption of sulphuric acid by the benzine solution of the oil. It is concluded that the test is absolutely useless for the valuation of lubricating and cylinder oils, although for a rough characterisation of crude petroleum products it may be of some utility.
—G. F. M.

Asphaltum in petroleum and its distillation products; Determination of ——. K. Charitschkoff. Njeftjanoje Djelo, 1913, No. 13; Petroleum, 1914, 9, 690—691.

Colorimetric and densimetric methods have been suggested, but have not been found practicable. The French method, although imperfect, is the only one in use: the oil, dissolved in benzine, is shaken with sulphuric acid, and the quantity dissolved is taken as the asphaltum (compare preceding abstract). Secondary reactions, such as polymerisation, addition, etc., cause errors. The iodine value gives the content of unsaturated hydrocarbons, which should be deducted from the asphaltum.—O. E. M.

Naphthenic acids; Investigation of —— from heavy commercial lubricating oils. V. Herr. Petroleum, 1914, 9, 1198—1199.

An aqueous solution of the commercial product known as "muilonapht" gave on addition of sulphuric acid an oil of sp. gr. 0·9476, and refractive index 1·4848. The low gravity compared with that of the naphthenic acids from kerosene residues, 0·9621, is considered to be due to the presence of a neutral oil which was isolated by distilling the potassium salt of "muilonapht" with superheated steam till nothing but water distilled over. A solar oil of sp. gr. 0·8878 was obtained as distillate, and the residue on acidification gave naphthenic acids which on distillation in vacuum formed a yellow oil of sp. gr. 0·8737. Another method consisted in fractionating the methyl esters obtained by esterifying the acids in the crude oil liberated by sulphuric acid from "muilonapht." The fraction 270° to 350° C. was saponified and an acid of sp. gr. 0·9578 obtained. From another commercial naphthenic acid an acid of sp. gr. 0·9702 was isolated by the potassium salt method. These experiments indicate that the naphthenic acids obtained from the higher-boiling fractions of Baku petroleum belong to the same homologous series as the kerosene naphthenic acids, and that the specific gravities of the technically pure naphthenic acids from both fractions are almost the same. This is not in accord with the observations of Albrecht (Chem. Rev. Fett-Ind., 1911, 18, 152 and 189) who found that the rise in boiling-point was accompanied by a decrease in specific gravity.—G. F. M.

Physiological effect of methane. Rybak. *See* XIXb.

PATENTS.

Fuel; Composition ——. W. T. Vint, Bradford, and S. G. Grimshaw, London. Eng. Pat. 20,625, Oct. 6, 1914.

A SMALL proportion of the fibrous root of the canna plant is added to a mixture of coal and pitch, before briquetting, to prevent the finished briquettes from falling to pieces in the fire.—W. H. C.

Gas producers, blast furnaces, etc. Hoppers for ——. Babcock and Wilcox, Ltd., London. From The Babcock and Wilcox Co., New York. Eng. Pat. 23,054, Oct. 13, 1913.

A CYLINDRICAL hopper is provided midway of its height with a loose conical ring, which forms a seating for a valve opening downwards. This valve has a downward tubular extension enlarged at the lower end to form a combined spreader and valve which provides a second closure at the bottom of the hopper.—A. T. L.

Gas, oil and ammonia; Manufacture of ——. R. Maclaurin, Cambusbarron, Scotland. Eng. Pat. 24,426, Oct. 28, 1913.

PRODUCER gas containing at least 14% H_2 is passed upwards through a column of bituminous fuel above the producer chamber so as to form ammonia, and distil off tar and oils from the fresh fuel. The distilling chamber has metal walls with annular partitions inclined upwards and inwards so as to form troughs for collecting and withdrawing the oils which condense in the cooler part of the fuel column. The oils are thus prevented from running back into the hot fuel and being converted thereby into more viscous oils and finally into tar. The fuel is supported above the annular troughs by horizontal or inclined perforated annular plates. Part of the producer gas is withdrawn directly from the producer chamber, in order that the temperature of the fuel column may be kept at 700° C. decreasing gradually to 500° C. in the ammonia-generating zone, and below 500° C. in the distilling chamber. The draught is regulated so that the fuel remains in the ammonia-generating zone for 4 hours. The producer chamber is of comparatively large cross-section and has very thick walls to prevent loss of heat. For making illuminating gas and coke as well as oil and ammonia, a large producer chamber (diameter 8—10 ft. for burning 1 ton of coal per hour), with walls 2 ft. thick, is surmounted by an ammonia-generating and oil-distilling chamber of three-fourths the diameter and 4—5 ft. high. The producer chamber is blown alternately with air and with water-gas or coal-gas. The gas formed during the air-blow is drawn off at the top of the producer chamber, and the heated current of coal-gas or water-gas is passed up through the distilling chamber to an outlet at the top of the producer. Coke is withdrawn through lateral doors above the grate.—A. T. L.

Gas producers. P. A. J. Cousin, Loos-lez-Lille, France. Eng. Pat. 4673, Feb. 23, 1914. Under Int. Conv., Jan. 8, 1914.

A ROTARY grate for gas producers is formed with a deep annular trough around its outer edge for the reception of clinker and ash from an inclined radial channel in the grate. The central part of the grate forms a blast chamber having a number of tuyère openings. The tuyères which project upwards into the fuel have a cutting edge in the direction of their movement and air-discharge openings in their rear wall. The radial channel in the grate is covered by grate-bars which can be raised and lowered by cams. To facilitate the passage of the clinker and ash through the radial channel to the annular trough, a rod carrying hinged plates is worked to and fro in the bottom of the channel. A fixed inclined plate dipping into the annular trough removes the clinker from the trough as the latter rotates.—A. T. L.

Fire-grates for gas producer furnaces. W. P. Gibbons and C. J. McEwen, Dudley, Worcestershire. Eng. Pat. 12,582, May 22, 1914.

SEPARATE hanger-bars rest freely on a series of horizontal rods fitted at different heights across the grate-opening. The bars extend downwards and each rests upon the next below, thus forming an inclined grate, which projects downwards into the water-sealed ashpit. The separate bars are in contact where they rest on the rods, but are narrower at the lower part so as to leave air spaces. The top of each bar projects outwards horizontally, forming a shelf on which ashes can be placed to bank the fire. The surface of the bars exposed to the fire is grooved and water is run down it from an annular trough at the top of the grate.—A. T. L.

Gas-producer. J. H. Hirt, Sewickley, Pa., Assignor to Allis-Chalmers Manufacturing Co. U.S. Pat. 1,114,355, Oct. 20, 1914; date of appl., Nov. 30, 1908.

Two superposed cylindrical chambers are separated by a partition having a central opening. Fuel is fed through an oblique port near the bottom of the lower chamber and "moisture" through an oblique port near the top of this chamber. The producer gas is withdrawn from the upper part of the upper chamber.—W. H. C.

Gas-producer. C. M. Garland, Chicago, Ill. U.S. Pat. 1,114,979, Oct. 27, 1914; date of appl., Dec. 15, 1913.

THE producer comprises an upper chamber for the distillation of fresh fuel by means of a downward current of steam and gas, and a lower chamber in which gas is generated from the coked fuel by means of an upward current of steam and air admitted through a central tuyère. The steam is generated in an annular boiler which forms the wall of the upper chamber. This chamber is fitted with a depending bell which forms the fuel chamber and provides an annular space through which the gases pass from the top of the lower chamber to an outlet near the top of the producer. The steam passes, part through a three-way valve, and a superheating-coil in the walls of the producer, and part direct, to an injector nozzle which draws some of the gases from the lower chamber and delivers them into the upper part of the upper chamber to form the downward current of hot gases. A thermostat in the upper chamber controls the three-way valve so as to maintain the temperature of this heating current constant.—A. T. L.

Gas generator. G. Akerlund, Assignor to Standard Gas Power Co., Atlanta, Ga. U.S. Pat. 1,115,268, Oct. 27, 1914; date of appl., Feb. 2, 1912.

IN a down-draught gas-producer, the gas is withdrawn through a central collector in the lower or ash-zone, and the air and steam are admitted at a number of points around the wall of the producer at about the middle of its height. An independent supply of air and steam is also admitted at the top of the fuel column.—A. T. L.

Gas; Process of making ——. J. O. Carrey, St. Louis, Mo. U.S. Pat. 1,115,392, Oct. 27, 1914; date of appl., July 26, 1913.

AN inclined partition extends from the axis of the producer near its lower end to the upper part of one of the walls, and forms the side wall of a distillation chamber for the raw fuel. It is heated by the incandescent fuel beneath it and by the hot gases passing to the gas outlet. The coked fuel descends from the distillation chamber to the furnace chamber in the lower part of the producer and is moved by stirring arms so that all parts of the fuel are subject in turn to the blast which is admitted at separate points. Distillation gases drawn from the upper part of the producer are admitted at points between the blast inlets. —A. T. L.

Coal gas; Process for purifying ——. R. Fabry, Sheffield. Eng. Pat. 29, Jan. 1, 1914.

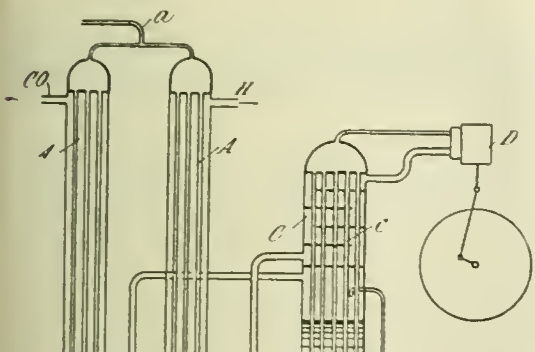
THE cooled and tar-free gas is washed with a solution of a mixture of alkali (preferably potassium) carbonate and caustic ammonia in such proportion as will take up the excess of H_2S, CO_2 and HCN over that which will be absorbed by the ammonia in the gas. The washing solution is regenerated by heating in a dissociating still and the vapours and gases given off are mixed with those from the ammonia liquor still and passed into a saturator containing sulphuric acid. The gases from the saturator are utilised by partial or complete combustion.—W. H. C.

Mixing the constituents of a combustible gaseous mixture; Method of and means for ——. A. C. Ionides, jun., London. Eng. Pat. 23,350, Oct. 15, 1913.

A DEVICE for mixing gas and air in a burner in the proportions requisite for complete combustion, and at the same time preventing backward propagation of the flame (see Eng. Pats. 15,455 of 1909 and 21,112 of 1911). The wall of the air conduit, which is surrounded by a gas chamber, is perforated with holes arranged spirally around it and increasing in number towards the burner. By this arrangement the mixture is richest at the part of the mixer nearest the burner and a backward propagation of the flame is retarded by the weaker mixture at the other end of the mixer. The orifices may be fitted with inclined tubes projecting into the air conduit, those tubes furthest from the burner leading furthest towards the axis of the conduit. The mixer may be used with the crucible furnace described in Eng. Pat. 2839 of 1912 (this J., 1913, 198).—A. T. L.

Gaseous mixtures [e.g., water-gas]; Separation of the constituents of ——. Soc. l'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude), Paris. Eng. Pat. 13,160, May 28, 1914. Under Int. Conv., May 29, 1913.

COMPRESSED water-gas enters the heat interchangers, A, A, through the pipe, *a*, passes through the tubes and away by the pipe, b^1, to the reservoir, B^1, and thence up the tubes, *b*, *c*. Carbon monoxide condenses and collects in the reservoir, B^1, and the cooled compressed hydrogen passes to the engine, D, where it expands, does work and is further cooled. The expanded hydrogen circulates round the upper part of the tubes, *b*, *c*, in the vessel, C, and completes the condensation of the carbon monoxide which was commenced in the lower part of the tubes by the cold produced by the evaporation of a previously liquefied portion of carbon monoxide which supplied the vaporiser, B, by the pipe, b^2, from the reservoir, B^1. The separated hydrogen and carbon monoxide pass through the jackets of one or other of the vessels, A, A, to the outlets.—W. H. C.



Hydrocarbons; Conversion of heavy into lighter ——. W. A. Hall, New York. Eng. Pat. 17,121, July 25, 1913.

HYDROCARBON vapours are heated to above 600° C. in the presence of a suitable catalyst and under a pressure of about 5 atmospheres. The vapours are then passed through an expansion chamber provided with screens for separating the free carbon, and through a condenser. Suitable catalysts are Ni, Co, Ag, Pd, Cr and Mn, and their oxides. Gas oil treated in this way yields 60—70% of oil of sp. gr. 0·765, suitable for petrol engines.—A. T. L.

Paraffins; Separation of solid —— from oils containing them. Allgem. Ges. f. Chem. Industrie m. b. H. Ger. Pat. 276,994, May 3, 1913.

SOLID paraffins may be separated from hydrocarbon oils by treatment with liquefied sulphur dioxide in presence of an unsaturated aromatic hydrocarbon which is soluble in liquefied sulphur dioxide and will dissolve the volatile paraffin hydrocarbons. In some cases, such as with the oils from lignite tar, treatment with liquefied sulphur dioxide alone is sufficient to separate the solid paraffins.—T. F. B.

Water-gas; Apparatus for the manufacture of ——. A. G. Glasgow, Richmond, Va., Assignor to The United Gas Improvement Co., Philadelphia. U.S. Pat. 1,115,065, Oct. 27, 1914. Date of appl., Nov. 11, 1911.

SEE Eng. Pat. 28,855 of 1910; this J., 1912, 64.—T. F. B.

Calorimeter. U.S. Pat. 1,115,238. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Distillation of hardwood; Effect of pressure on yields of products in the destructive ——. R. C. Palmer. J. Ind. Eng. Chem., 1914, 6, 890—893.

EXPERIMENTS were made with maple and birch sawdust and birch chips, 1×½×½ in. in size, distillation being effected in a cast-iron autoclave, 15½ ins. deep by 8½ in. inside diameter. The effect of pressure was to increase the yield of charcoal and gas and, to a slight extent, of wood alcohol and to decrease the yield of acetic acid, pyroligneous acid and tar. A greater effect was produced by increasing the pressure from atmospheric to 60 lb. than by a further increase. The greatest effect was on the yield of tar which was decreased 60—65% at 60 lb. pressure. It is suggested that possibly pyroligneous acid free from soluble tar might be obtained by subjecting the distillate to high pressure during the vapour stage. —A. S.

Gas lighting and hygiene. M. von Grüber. J. Gasbeleucht., 1914, 57, 690—691.

TESTS were carried out in rooms in which the conditions could be controlled. Sulphur dioxide and carbon monoxide could not be detected in the air in the rooms, even after the burners had been alight for 67 hours; traces of nitric oxide were usually present, the largest amount found being 10·4 c.c. per cb. metre. The quantity of carbon dioxide never exceeded 4 parts per 1000 and the temperature of the rooms was only raised a few degrees. In comparative experiments with gas and electric lights, the difference in the increase of the temperatures of the rooms amounted to 1·6° C., whilst the difference in moisture-content of the air was generally less than 5%. In the room lighted with electric lamps the ventilation was such that about one-third of the air was replaced per hour; in the room having gas lamps, two-thirds of the air was replaced per hour. The hot gases from the lamps did not appear to have any disinfecting effect on the air.—W. P. S.

Gas lighting and electric lighting in Japan. Iwabushi. J. Imp. Gas Assoc., Tokyo, 1914, No. 1. J. Gasbeleucht., 1914, 57, 600.

ALTHOUGH the gas industry is older than the electrical industry, the latter has surpassed the former owing to the mountainous nature of the country being especially favourable for small electric works with water power.

Fourteen towns with a total population of over six millions have nearly one million gas connections, or 124 per thousand inhabitants, whilst the electricity connections exceed two millions, equal to 272 per thousand inhabitants. —J. H. J.

Patents.

Coals and other hydrocarbonaceous substances; Apparatus for and process of treating ——. J. D. Scott, New York. U.S. Pats. 1,115,453 and 1,115,454, Oct. 27, 1914; date of appl., Aug. 26, 1910.

The materials are spread in thin layers on a number of superposed perforated trays spaced apart within a double-walled chamber. Hot gases are circulated through the space between the walls and then downwards over the material to an exhaust pipe.—W. H. C.

Distilling wood, peat, moss, straw, etc.; Process for ——. H. Plauson and G. von Tischenko. Ger. Pat. 276,811, Dec. 22, 1912.

A combined distillation and extraction of wood, peat, moss, straw, and similar materials, is effected, with only a very small production of gas, by treatment with superheated steam and the vapours of a solvent, such as an alcohol, naphtha, an oil, etc. Addition of alkali or alkaline-earth salts produces a catalytic effect, resulting in the formation of larger quantities of liquids of low boiling-point, such as turpentine and terpenes from pine wood. A higher yield of ketonic or other oxygen compounds, lubricating oils, etc., is obtained if the mixture of steam and solvent is heated to 300°—600° C.—T. F. B.

Arc-light electrode. A. V. Wilker, Berea, Ohio, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,114,953, Oct. 27, 1914; date of appl., Jan. 22, 1912.

The electrode contains a silicide of a rare earth metal, *e.g.*, cerium silicide.—A. T. L.

Incandescence bodies made of tungsten or similar metal; Process for making —— *of uniform diameter.* Allgem. Elektricitäts-Ges. Ger. Pat. 276,037, July 27, 1913.

Wires of tungsten or similar metals, for use in incandescence lighting, are heated in presence of a substance which will, under these conditions, attack the thicker parts, which are less strongly heated. For example when tungsten wire is heated electrically in presence of hydrogen containing less than 1% of oxygen, the thicker parts, heated to a red heat, are oxidised, whilst the thinner parts, which become more strongly heated, are not oxidised. Nitric acid may be used for the same purpose, and is suitable for treating wires of tungsten, molybdenum, or tantalum.—T. F. B.

Arc-light carbon. H. Ayrton, London. U.S. Pat. 1,115,480, Nov. 3, 1914. Date of appl., March 7, 1914.

See Eng. Pat. 1775 of 1913; this J., 1914, 346.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Tar and its derivatives; Applications of ——. Kayser. J. Gasbeleucht., 1914, **57**, 200—203 and 220—231.

Owing to the large amount of benzene for use in dye manufacture recovered in the production of coke in coke-ovens, new outlets are necessary for the tar and its derivatives produced in gas works. The use of tar oil as fuel in furnaces and engines is one such. In furnaces the oil should be supplied under pressure and then broken up by air streams. A flat stream issuing under low pressure appears better than spraying through easily choked fine orifices. In the Irinyi apparatus the oil is vaporised in a retort in the furnace, oil flowing to the retort by gravity. The advantages of tar-oil in furnaces are smokeless firing, simplicity of working and cheapness. Tar oil is also used in Diesel engines; and Körting's have a plant of 500 H.P. running with tar from vertical retorts: this works as well as a tar oil installation while the cost of fuel is less, but a special starting means is necessary. Tar has also been used in furnaces. Tar is in demand for road making and for coating wood, etc., especially in roof work. Pitch is used in the coal briquetting industry. Separate works for the distillation of 175—200 tons of tar per annum are not profitable. Combined working of such outputs should be resorted to. Both continuous and discontinuous distillation processes are used. A continuous plant of H. Hirzel comprises a raised reservoir into which tar is pumped, and whence it flows through a vertical chamber having horizontal baffles and heated to 180° C. to drive off water and light oils. It then passes through a series of three stills, placed side by side and stepwise. In the first medium oils are driven off, in the second heavy oils, and in the third anthracene, the pitch being drawn off through a cooler into pits. The distillates are passed through condensers into reservoirs. A fourth still is used alternatively as the third in the series, and alternate cooling tanks are used for the pitch. In the discontinuous process a vertical retort is usual, the means for driving off water and light oils being the same as in the continuous process. For large plants a vacuum process is desirable. In the Sadewasser system, tar in a continuous stream is passed through a superheater and sprayed in a vacuum chamber; the ensuing vapour is condensed in fractional cooling chambers. Pitch is suggested as an alternative to cement for building purposes.—W. F. B.

Use of heavy oils (tar, tar oils) in internal-combustion engines. Drexler. *See* IIa.

The sale of tar. Chem. Trade J., Nov. 28, 1914.

The following conditions relative to the sale of tar have been agreed upon by the Joint Committee of the Institution of Gas Engineers representing tar producers and distillers, and are recommended for adoption throughout the United Kingdom.

I.—*Sliding-Scale Contracts.*—(a) The tar distillers and gas authorities, or their valuers, to meet each month as usual, to fix the values of the products other than pitch. (b) The tar distillers to pay to the tar producers the aggregate value of such products, *plus* 2s. 6d. per ton of tar on account, for the pitch, less the usual 2½% and working expenses. (c) All pitch made and delivered since August 1, 1914, by individual tar distillers during the period of crisis to be paid for each month *pro rata* to the deliveries of tar of each producer, allowance being made for the 2s. 6d. per ton of tar already paid on account. (d) On the resumption of the export of pitch at present suspended, the value of such pitch delivered each month to be settled by the usual arbitrators, and the value ascertained each month to be added to the tar values and paid by the tar distillers to the tar producers, less the 2s. 6d. per ton of tar already paid on account. (e) The additional cost (if any) incurred by the removal and storage of pitch to be equally borne by the tar producers and the tar distillers.

II.—*Price-Fixed Contracts.*—(a) The sum of 17s. 6d. per ton of tar to be paid by the distillers and accepted by the producers in part payment as the value of products other than pitch and part value of pitch. (b) The balance to be paid as and when the pitch is delivered by the distillers *pro rata* to the deliveries of tar of each producer.

III.—*Minimum Price of Pitch.*—A committee has been appointed to consider and, if advisable, to fix prices from time to time.

IV.—*Revision of Conditions.*—These conditions may be amended by mutual arrangement between the tar producers' committee and the tar distillers from time to time.

IV.—COLOURING MATTERS AND DYES.

Dyes and other products from the waste liquor of the soda cellulose process Cram. *See* V.

Explosion in a dyestuff plant in the United States. Oil, Paint, and Drug Rep., Nov. 16, 1914.

A series of explosions, which resulted in the death of one man and injury to 26 others, occurred in the dyestuff plant of Dr. W. Beckers, Brooklyn. Experiments on the manufacture of certain azo dyestuffs were in progress, and it is believed that the accident was due to unskilful handling of the diazo salts.

Patents.

Azo dye ; Yellow ——. K. Hagemann, Leverkusen, Germany, Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,114,750, Oct. 27, 1914. Date of appl., April 21, 1914.

An aminoacidyl compound of an o-aminophenolsulphonic acid (*p*-aminobenzoyl-2-amino-4-chloro-1-phenol-6-sulphonic acid) is combined with a methylketol compound (2-methyl-indole) ; when printed on the fibre with chromium acetate as mordant, these dyestuffs give yellow shades fast to light and milling.—T. F. B.

Isatin ; Preparation of an oxidation product of ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 276,808, June 12, 1913.

Isatin is oxidised by means of permanganate in neutral aqueous suspensions ; a yellow crystalline compound, $C_{16}H_8N_2O_2$, is obtained, of m. pt. 262° C., which is very reactive and therefore suitable for use in preparing indigoid dyestuffs. It is converted into Indigo White when heated with excess of alkali and sodium hydrosulphite.
—T. F. B.

Vat [anthracene] dyes. A. Hamburger, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,115,188 and 1,115,189, Oct. 27, 1914. Dates of appl., Dec. 26, 1911, and July 25, 1912.

See Eng. Pat. 12,865 of 1912 ; this J., 1912, 1025.—T. F. B.

Monoazo dyestuff. H. Jordan and W. Neelmeier, Leverkusen, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,114,711, Oct. 27, 1914. Date of appl., April 16, 1913.

See Eng. Pat. 17,322 of 1912 ; this J., 1913, 862.—T. F. B.

Azo dyes. A. Zart, Opladen, and H. Schweitzer, Leverkusen, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pat. 1,114,844, Oct. 27, 1914. Date of appl., Dec. 3, 1913.

See Fr. Pat. 465,794 of 1913 ; this J., 1914, 639.—T. F. B.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Oxycellulose in linen goods. M. Saget. Assoc. Gén. des Chimistes de l'Ind. Textile. J. Soc. Dyers and Col., 1914, 30, 331.

The formation of oxycellulose during the "creaming" of linen is suggested as the cause of the loss of strength during the bleaching process. This oxycellulose could not be detected by chemical tests, but its presence was demonstrated by measuring the strength of the fibre after steaming and treating with alkali. Linen which has been partly converted into oxycellulose tenders under the influence of sunlight and rain. The presence or absence of chlorine in the fibre is not considered to be necessarily an indication of its strength (see this J., 1908, 27, 260).
—T. F. B.

Soda pulp from aspen ; Effects of varying certain cooking conditions in producing ——. H. E. Surface. U.S. Dept. Agric., Bull. No. 80, Aug. 31, 1914, 1—63.

The variable conditions separately studied were : proportion of NaOH to wood ; time of digestion ; temperature or pressure ; initial concentration of NaOH. Increase of any of these factors increases the severity of the digestion, which is measured by the quantity of NaOH neutralised per unit weight of wood, and decreases the yield of pulp and the amount of bleaching powder required to bleach it. Severity of digestion may be judged by the microscopic appearance of the pulp ; in over-boiled pulps the walls of the fibre are weakened and transparent, those of the vessels and cells partly obliterated ; in under-boiled pulps the walls of all the elements are dense, and sharply defined : fibre-aggregates are common. The strength of the pulp may either decrease or increase with increased severity of treatment ; when this is produced by increasing the proportion of NaOH or the time of digestion, the strength of the pulp decreases, but when it is produced by increasing the temperature or the initial concentration, the strength of the pulp may increase, possibly owing to the production of hydrated cellulose. The decreased yields resulting from more severe digestion involve a greater cost for wood and alkali per ton of pulp and a point is soon reached at which these costs are not compensated by the lower cost of bleaching. Aspen wood may be successfully digested with a minimum charge of 20—25% of NaOH on the dry weight of wood and a consumption efficiency up to 95% of the NaOH present can be obtained by suitable adjustment of the temperature and time of digestion. In the experiments, using only clean, sound, picked wood of the best quality, yields as high as 56—58% of well-separated unbleached fibre were obtained ; with yields of 54—55% the pulp bleached well with 10—11% of bleaching powder. These results are 10—25% better than those reported from pulp mills working with ordinary wood under practical conditions. Of the factors of cost, that of the wood is of the most importance, next comes bleaching powder, and lastly alkali. Tables and curves are given showing the influence of the variable factors of digestion upon yield, bleaching quality, colour, freedom from shive and strength of the pulp, and the various digestions are illustrated by samples of the pulp produced. In illustration of the conditions adopted for the preparation of a clean, easy-bleaching pulp, the following particulars may be cited from the tables : weight of air-dry chips, 40 lb. ; initial volume of lye per lb. of dry wood, 0·376 gall. ; concentration of NaOH, 80 grms. per litre ; proportion of NaOH to dry chips, 25% ; total time of digestion, 8 hrs. ; time at maximum pressure, 7 hrs. ; maximum pressure 100 lb. per sq. in. ; yield calculated dry 52·5% ; bleaching powder required, 9·0—9·5%. When the time at maximum pressure was reduced to 5 hrs., the yield was 53·7% and the consumption of bleaching powder 10·5%.—J. F. B.

Sodium peroxide for bleaching rag half-stuffs ; Suitability of ——. von Possanner. Wochenbl. Papierfab., 1913, 3161 ; Chem.-Techn. Rep., 1914, 38, 241.

Experiments with sodium peroxide as a substitute for bleaching powder for bleaching rag half-stuffs showed that its bleaching action is very feeble and that even for improving the colour of pulps already bleached it is not particularly satisfactory and can only be recommended in exceptional cases where complete freedom from chlorine compounds is essential and cost of little consequence.
—J. F. B.

Dyes and other products from the waste liquor of the soda cellulose process. M. P. Cram. J. Ind. Eng. Chem., 1914, 6, 896—897.

100 c.c. of the crude black liquor of sp. gr. 1·25 were treated with 30 c.c. of hydrochloric acid of sp. gr. 1·18 and heated to boiling. The precipitate produced (yield 14 grms.) agglomerated into plastic lumps which became brittle on cooling. It was composed entirely of organic matter and was soluble in alkalis and dilute alcohol. When dissolved in caustic soda it could be used as a size for paper, to which it imparts a reddish-brown tint, or as a stain for wood. Its alcoholic solution could also be used as a wood stain. It is partly soluble in chloroform and the soluble part, dissolved in a volatile solvent, could be used as a varnish. When heated with potassium sulphide and sulphur to 185°—230° C. it yielded a dyestuff giving

dark brown or black shades, fast to light, on wool, silk and unmordanted cotton. Brown to yellow wool dyes were obtained by nitrating the precipitate or the original liquor. The filtrate from the precipitate yielded, on distillation, acetic acid and an organic compound, probably a phenol, which yielded products capable of dyeing wool and silk when treated with various reagents.—A. S.

Recovery of spent lime from causticising operations. Payne. *See* VII.

PATENTS.

Textile fibres, goods and fabrics ; The conditioning of ——. E. L. Joseph, London. Eng. Pat. 24,043, Oct. 23, 1913.

THE material is treated in a closed chamber with a gaseous oxidising agent such as ozonised air, a series of chambers and fans being so arranged that the ozonised air may be discharged either from one chamber to the next or into the atmosphere. The oxidising strength of the ozone is progressively increased in the later stages of the treatment. Animal fibres are preferably treated after the oiling process when in the form of rovings or sliver, vegetable fibres preferably after the bleaching and before the spinning operation.—J. F. B.

Crape and crimped or embossed fabric from cotton or thread made from cellulose ; Manufacture of ——. Courtaulds, Ltd., London, and W. S. Gilles, Braintree, Essex. Eng. Pat. 13,150, May 28, 1914.

FABRICS of cotton or artificial cellulose threads are treated with a solution of acetate or other salt of aluminium, or else first with albuminous or gelatinous matter and formaldehyde and subsequently with the aluminium acetate, then heated, dried and crimped or embossed. The crimped fabric is finished by applying a dressing, *e.g.*, a solution of shellac in alcohol or of gelatin in the form of a spray to one or both sides and drying.—J. F. B.

Paper pulp ; Apparatus for straining ——. W. W. Beaumont, London. Eng. Pat. 25,082, Nov. 3, 1913.

IN strainers of the "jog-knotter" type, the strainer plates and their frame are mounted upon spring-supported bearings arranged at opposite sides of the vat and vibratory motions are imparted to the bearings on one side only, so that the entire inner vat partakes of a vibratory movement about a longitudinal axis which passes through the centre of gravity of the mass moved, the same actuating motions operating, in conjunction with the reactions of the bearing springs, to impart to the vat an up-and-down movement. —J. F. B.

Drying machine [*for paper stock*]. J. O. Woodsome, Assignor to Crane Co., Chicago, Ill. U.S. Pat. 1,114,215, Oct. 20, 1914 ; date of appl., Aug. 19, 1911.

THE paper stock is passed successively over two systems of heated rollers. The system with which the paper comes last into contact is heated by direct steam and the exhaust steam from this system passes through a controlling device to the rollers of the other system where it is condensed. —W. H. C.

Waste sulphite liquor ; Bleached ——, *and process of preparing same.* M. F. Coughlin, Stroughton, Mass., and C. E. Swett, Providence, R.I, Assignors to F. H. Kennard, Newton Center, Mass. U.S. Pat. 1,114,120, Oct. 20, 1914 ; date of appl., Feb. 21, 1914.

THE waste sulphite liquor is first treated with an oxidising agent (permanganate) and then with a reducing agent (hydrosulphite).—J. B.

Rosin soap sizing composition. J. A. De Cew, Montreal, Canada. Eng. Pat. 12,686, May 22, 1914.

SEE U.S.Pat.1,099,168 of 1914 ; this J.,1914, 785.—T. F. B.

Finishing composition, and method of preparing same [*from waste sulphite liquor*]. U.S. Pat. 1,114,119. *See* VI.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Bleaching ; The theory of ——. S. H. Higgins. J. Soc. Dyers and Col., 1914, 30, 326—328.

THE bleaching action of hypochlorous acid is due initially to the direct production of oxygen, but as the bleaching proceeds, hydrochloric acid accumulates and reacts with hypochlorous acid according to the equation, $HOCl+HCl=H_2O+Cl_2$. This action is reversible, the reverse direction representing the behaviour of chlorine water (see this J., 1912, 486), and in each case when equilibrium occurs the bleaching action ceases. When a hypochlorite is used for bleaching, the hydrochloric acid produced is used in liberating more hypochlorous acid. The removal of free hydrochloric acid from either chlorine water or hypochlorous acid by addition of calcium carbonate has been shown experimentally to accelerate the bleaching action. Taylor's observation (this J., 1914, 308) that there is always a certain amount of residual colour in cotton treated with hypochlorous acid or chlorine water, is explained by this state of equilibrium ; when calcium carbonate is added, the cotton is completely bleached. The colouring matters of brown linen and of boiled cotton are at once partially bleached on immersion in chlorine water, but prolonged treatment has very little further effect. The action of bleaching powder solutions on cotton dyed with direct and basic dyestuffs has been examined ; in a number of cases the solutions to which hydrochloric acid was added caused a change of colour, whilst when boric acid was added, no such change was observed. In the majority of cases the solutions containing hydrochloric acid had the more rapid bleaching action ; with Alizarin Sapphirole, however, the reverse was the case. The author concludes that the bleaching action of hypochlorites is due to the direct production of oxygen and to the production of nascent chlorine. Thus, it has been found that a large quantity of acetaldehyde is produced on warming dry calcium hypochorite with alcohol, whilst it is known that bleaching powder can convert alcohol into chloroform. It is considered that the nascent chlorine is formed by the interaction of the chloride with the free hypochlorous acid. The effect of the calcium chloride produced during bleaching with bleaching powder is shown to be negligible, but when calcium chloride is added during the bleaching process it always has a stimulating effect, showing that hypochlorous acid is present during the whole process. Attention is drawn to the importance of using carefully prepared fibre in bleaching experiments, and of making allowance for the fact that the colouring matters of cotton and linen are of an acid nature, especially in comparing the bleaching actions of acid and alkaline solutions. (See also this J., 1911, 485 ; 1914, 785.) —T. F. B.

Sodium perborate ; [*The true value of* —— *in bleaching*]. W. Kind. Z. ges. Textil-Ind., 1913, **16**, 1045. Chem.-Techn. Rep., 1914, **38**, 123.

ALTHOUGH perborate cannot compete with the chlorine bleach on the ground of cost, yet it has advantages over hydrogen peroxide, mainly on account of the ease with which a solution of the required strength can be made up and the way in which it gradually gives up its oxygen without the development of too great a degree of alkalinity. Perborate has advantages for special purposes in bleaching, *e.g.*, for coloured and finished goods. As a starch remover it can compete in certain circumstances with "Diastafor." It destroys active chlorine but not chloramines. In dyeing it is used for after-treating vat and sulphide dyes, in cleaning for removing stains and for bleaching feathers, etc. It has found its greatest application in the laundry on account of being safer than the chlorine bleach. Generally its use in ordinary bleaching is too expensive. —J. B.

Dyed textiles; Loss of colour on storing ——. P. Heermann. Leipz. Monatsschr. Textil-Ind., 1913, **28**, 204, 237 and 268. Chem.-Techn. Rep., 1914, **38**, 121.

The loss of colour may be due to such a large variety of causes that no single method of testing the fastness of dyed material is available. Conditions of storage have great influence: for instance gases given off by the lighting arrangements sometimes cause trouble. The most common causes of damage are heat and light, with varying conditions of moisture.—J. B.

Garments; Improvised waterproofing of military ——. G. A. Le Roy. Comptes rend., 1914, **159**, 633—634.

Wool fat is melted with a little chloroform, carbon bisulphide or tetrachloride and then at once dissolved in motor spirit or other industrial hydrocarbon to form a 5—10% solution. If a non-inflammable solution be desired, the hydrocarbon may be blended with half its volume of carbon tetrachloride or dichloroethylene. Garments steeped in this solution for a few minutes, wrung out and dried in the air become effectively waterproofed and retain this quality when in use; the appearance and physical qualities of the cloth are quite unaffected.

—J. F. B.

Patents.

[*Scouring.*] *Treating cheeses, cops, etc. of woollen yarn preparatory to warping.* H. Heymann, Bradford. Eng. Pat. 28,294, Dec. 8, 1913.

Cheeses, cops and similar forms of yarn spun from previously dyed wool are degreased by means of a volatile solvent, thus avoiding the hanking of the yarn for the usual scouring or the energetic scouring required when this operation is performed on the woven piece.—J. B.

Bleaching fabrics; Apparatus for ——. J. T. Niblett, London. Eng. Pat. 26,727, Nov. 20, 1913.

A rotary laundry machine comprising a drum mounted in a stationary casing is provided with electrodes fitted either to the rotary drum or to the outer casing; in the latter case the electrodes may be contained in a recessed opening or sump over which the solution flows during the treatment. The electrolyte consists of a solution of a suitable chloride in which the goods are rotated while electrolysis is taking place.—J. F. B.

[*Dyeing hat bodies.*] *Apparatus for agitating solid bodies in a liquid.* J. H. and W. Robinson, Stockport. Eng. Pat. 17,125, July 20, 1914.

The hat bodies are agitated in the dye-bath by means of a vane revolving round a central axis. The vane projects a little above the surface of the liquor and is of such a size that a space is left between its outside edge and the wall of the vat.—J. B.

Dyeing machine. J. H. and D. M. Giles, Amsterdam, N.Y., Assignors to J. H. Giles Dyeing Machine Co., Portland, Me. U.S. Pat. 1,114,464, Oct. 20, 1914; date of appl., Dec. 29, 1913.

The yarn is carried on sticks supported on a wheel which revolves partially immersed in the dye-bath. The sticks have star wheels at their ends and ratchet arrangements to cause them to revolve periodically, somewhat after the manner of the Klauder-Welldon machine.—J. B.

Dyeing or washing machine. H. Hennig, Paterson, N.J. U.S. Pat. 1,115,072, Oct. 27, 1914; date of appl., Aug. 10, 1911.

Yarn is hung on sticks in a tank on either side of which are vertical flues fitted with air injectors and having at their tops deflecting plates for directing the liquid and air laterally and downwards into the centre of the tank.

—J. B.

Finishing composition and method of preparing same [*from waste sulphite liquor*]. M. F. Coughlin, Stroughton, Mass., and C. E. Swett, Providence, R.I., Assignors to F. H. Kennard, Newton Center, Mass. U.S. Pat. 1,114,119, Oct. 20, 1914; date of appl., Sept. 22, 1913.

A waxy material, with or without a soluble soap, is incorporated with waste sulphite liquor in such proportion as to be readily emulsifiable with water.—J. B.

Hanks of thread, etc.; Apparatus for liquid treatment of ——. J. Clayton, Coventry, Assignor to Courtaulds, Ltd., London. U.S. Pat. 1,116,242, Nov. 3, 1914. Date of appl., Oct. 28, 1913.

See Eng. Pat. 9067 of 1913; this J., 1914, 197.—T. F. B.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Spent lime from causticising operations [*and in sugar factories*]; *Recovery of the* ——. J. H. Payne. J. Ind. Eng. Chem., 1914, **6**, 937—939.

The long rotary kiln such as is used for Portland cement manufacture has been applied successfully in the Western United States for re-burning the spent-lime obtained in the manufacture of beet sugar and more recently to the re-burning of the spent-lime from causticising in alkali and wood-pulp factories. The capital cost of a plant with a capacity of 30 tons per day would be about 17,000 dollars (£3540) and the working expenses for a plant using producer-gas would be:—

	s.	d.
Fuel, 500 lb. coal at 12s 6d. per ton (2000 lb.)	3	1½
Labour, 2 men at 10s. 5d. and 2 men at 8s. 4d.	1	3
Repairs (including 1 lining per year at £188)..........		8
Power, 30 H.P. at £8 for year		5½
Interest and depreciation		9½
Taxes and insurance		2
Yard labour, supplies and miscellaneous		7½
Unforeseen		8
Total cost per ton of lime recovered	7	9

With a properly designed plant practically no dust is produced and the waste gases leave the kiln at about 350° F. (177° C.). The recovered lime slakes and causticises more slowly than fresh lime, but settles much more rapidly.—A. S.

Preparing neutral ammonium citrate solution. McCandless. *See* XVI.

Ammonium sulphate standard. Chem. Trade J., Nov. 28, 1914.

The chairman of the Sulphate of Ammonia Association has issued a circular to the members urging them to improve the quality of the product and to make sulphate which tests from 24¾ to 25% ammonia, with not more than 3% moisture and not more than ½% acid, adopting if possible, 25% as a selling basis. It is believed that the adoption of these standards will enable British manufacturers to compete in markets from which they have been or are being excluded.

Patents.

Alumina compounds; Solutions of ——. [*Stable sodium aluminate solution.*] H. Spence, T. J. I. Craig, and P. Spence and Sons, Ltd., Manchester. Eng. Pat. 20,970, Sept. 17, 1913.

Commercial sodium aluminate solution is treated with a small proportion of an organic substance capable of inhibiting the spontaneous separation of aluminium hydroxide; for example, it is heated for about 2 hours at 100° C. with 0·5—1·5% of sugar.—F. Sodn.

Hydrous alkali-metal silicate and method of producing it. E. A. Paterson, Port Arthur, Ontario, Canada. U.S. Pat. 1,111,918, Sept. 29, 1914 ; date of appl., Dec. 17, 1913.

A dry powder containing a large percentage of silica is produced by partially drying an alkali silicate at a comparatively low temperature and under reduced pressure, so as to form a solid mass, coarsely grinding the product, further drying and grinding to a fine powder, and then again drying until the water content (preferably reduced to 12—19% of combined H_2O) is only sufficient, in connection with the alkali present, to render the material readily soluble in cold water.—F. Sodn.

Barium and strontium oxides ; [Continuous] Process of producing ——. H. G. Akers, Toronto, Canada. U.S. Pat. 1,113,178, Oct. 13, 1914 ; date of appl., May 8, 1913.

Crude barium or strontium carbonate, mixed with a flux and a reducing agent, is melted at about 1200° C., preferably in a carbon-lined furnace in which a reducing atmosphere is maintained, and the mass refined by again adding a reducing agent, the evolved gases being ignited to heat the charge and preheat the incoming charge. Any carbon dioxide liberated from the charge may be diluted with the combustion gases from the fuel employed in heating the furnace, in order to lower its partial pressure. —F. Sodn.

Nitrogen ; [Cyclic] Methods of fixing ——. J. E. Bucher, Coventry, R.I., Assignor to Nitrogen Products Co. U.S. Pats. (A) 1,113,598 and (B) 1,113,599, Oct. 13, 1914 ; dates of appl., Aug. 8, 1911 and May 12, 1913.

(A) A salt, *e.g.*, a haloid salt, of a metal capable of forming a nitride, is electrolysed, and the separated metal converted into nitride by reaction with nitrogen or a nitrogenous reagent, and the nitride treated with a hydrogen compound (*e.g.*, halogen acid prepared from the electrolytic halogen) or an ammonia-halogen compound, so as to yield ammonia, or substance containing ammonia, and the original salt. (B) A metallic nitride, produced as above, is treated with a hydrogen compound (such as water), so as to form a substance containing ammonia and an oxygen or other compound of the metal, and the latter is converted by treatment with at least one reagent (preferably halogenous in character) into a salt which can be electrolysed. —F. Sodn.

Magnesium sulphate from residues of potash salt manufacture containing kieserite ; Preparation of——. R. Heintz Techn. Buro f. d. Chem. Ind., G. m. b. H. Ger. Pat. 275,702, March 6, 1913.

The residual products containing kieserite, obtained in the treatment of carnallite and "*Hartsalz,*" are dissolved in dilute magnesium chloride solution at about 80°—100° C., and the solution is completely or partly saturated with sodium chloride at the same temperature and allowed to cool, whereupon magnesium sulphate crystallises.—T. F. B.

Ammonia from its elements ; Process for obtaining —— using cerium nitride as catalyst. Kunheim und Co. Ger. Pat. 276,986, June 20, 1912.

A mixture of nitrogen and hydrogen under pressure is passed over a heated catalyst consisting of cerium nitride (obtained by the action of nitrogen on coarsely powdered cerium) or a substance containing not less than 20% of cerium nitride.—T. F. B.

Ammonia from its elements ; Catalytic preparation of ——. F. Hlavati. Ger. Pat. 277,054, June 19, 1910. Addition to Ger. Pat. 275,343.

A mixture of nitrogen and hydrogen is subjected to treatment by electric spark discharges and passed over a catalyst which has the power of absorbing both nitrogen and hydrogen. When a catalyst consisting of platinum and titanium is used, the temperature of the catalyst is regulated to induce absorption first of the hydrogen by the platinum and then of the nitrogen by the titanium ; the temperature is then raised to such a degree, not above 500° C., that the gases are liberated in an active condition. The pressure is increased or decreased according to whether absorption or evolution of the gases is taking place.—T. F. B.

Hydrogen ; Process for liquefying commercial —— by expansion. J. E. Lilienfeld. Ger. Pat. 276,657, Dec. 23, 1910.

The compressed hydrogen, containing 1 to 2% of air, is allowed to expand in two or more stages, and at one of the intermediate stages the pressure and temperature are so regulated that the air separates in the form of a liquid, but is not solidified. A temperature of about —215° C. is suitable for this purpose.—T. F. B.

Gaseous mixtures ; Separation of easily condensed or absorbed constituents from hot, compressed ——. J. Ephraim. Ger. Pat. 276,718, Dec. 14, 1912.

The gaseous mixture is cooled and expanded, then passed through a condensing or absorption apparatus, and again heated and compressed by aid of the heat and energy obtained in the first stage of the process. The process may be applied to the separation of ammonia from the gaseous mixtures produced in the catalytic process.—T. F. B.

Nitric acid ; Process of concentrating ——. F. Hausmann, Assignor to Verein Chemischer Fabriken in Mannheim. Mannheim, Germany. U.S. Pat. 1,115,192, Oct. 27, 1914. Date of appl., Sept. 9, 1913.

See Fr. Pat. 462,290 of 1913 ; this J., 1914, 311.—T. F. B.

Nitrate of lime and other salts ; Reduction of —— to powder. Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. Eng. Pat. 468, Jan. 7, 1914. Under Int. Conv., Jan. 23, 1913.

See Fr. Pat. 466,963 of 1914 ; this J., 1914, 865.—T. F. B.

Nitrates ; Production of commercially pure ——. C. Bosch and W. Wild, Ludwigshafen, Germany, Assignors to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,115,164, Oct. 27, 1914. Date of appl., June 22, 1909.

See Ger. Pat. 210,167 of 1908 ; this J., 1909, 656.—T. F. B.

Nitric oxide ; Electrodes for use in the production of——. C. Rossi, Legnano, Italy. Eng. Pat. 23,959, Oct. 22, 1913. Under Int. Conv., Oct. 22, 1912.

See Fr. Pat. 463,821 of 1913 ; this J., 1914, 421.—T. F. B.

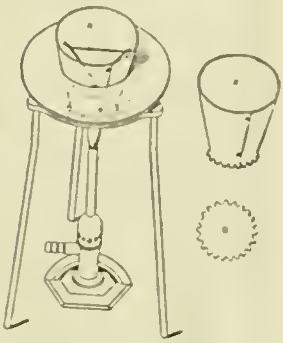
Hydrogen ; Producing ——. C. Bosch and W. Wild, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,115,776, Nov. 3, 1914. Date of appl., June 30, 1913.

See Fr. Pat. 459,918 of 1913 ; this J., 1914, 24.—T. F. B.

VIII.—GLASS ; CERAMICS.

Glass analysis ; Some rapid methods for ——. E. C. Sullivan and W. C. Taylor. J. Ind. Eng. Chem., 1914, 6, 897—899.

The glass is decomposed by a mixture of hydrofluoric acid and oxalic acid (instead of suphuric acid). For glasses



containing only silica, lead, soda and potash, with small amounts of iron, alumina, manganese, lime and magnesia as impurities, 1 grm. of the finely-powdered sample is moistened with water in a platinum crucible of about 40 c.c. capacity, and 2 grms. of oxalic acid and enough 48% hydrofluoric acid to half-fill the crucible are added. The mixture is evaporated to dryness on a radiator (see below) at a temperature just high enough to expel the excess of oxalic acid. When all the acid is expelled the crucible is cooled and the evaporation repeated twice more with oxalic acid (about 5 grms. in all) and water. The residue is treated with hot water, cooled, and filtered. The insoluble portion consists of lead oxalate, with a trace of calcium oxalate, and may be titrated with permanganate or the lead determined as sulphate. The filtrate is evaporated, the residue heated to decompose the oxalates, dissolved in dilute hydrochloric acid and evaporated to remove silica. The residue is treated with hot water and a few drops of hydrochloric acid, and a few drops of bromine water and a little ammonia added to the solution which is boiled, and the precipitated hydroxides of iron, aluminium, and manganese filtered off. In one portion of the filtrate, any magnesium is precipitated as magnesium ammonium phosphate and calculated to chloride. The remainder is evaporated, heated to expel ammonium salts, and the chlorides weighed, the weight of magnesium chloride found and also the alkali obtained in a blank determination being deducted. The potassium is determined with platinum chloride and the sodium obtained by difference. In the case of glasses containing other elements, Ca and Zn give insoluble oxalates ; Cd is also insoluble, but in presence of Zn traces are found with the soluble oxalates ; Co, Cu, Ni, Ba, and Mg oxalates are mostly insoluble, but must be tested for in the soluble oxalates unless special precautions be taken ; Na, K, Al, Cr, and As are found with the soluble oxalates ; Mn up to 2% is soluble, but with larger quantities partly insoluble ; Fe is soluble, but in presence of Zn traces remain insoluble ; Sb is usually soluble unless the oxalates be heated too strongly. Borates do not interfere, but the results are not satisfactory when more than 3% Al_2O_3 is present. A complete analysis can be made in a day.

The success of the method depends to a considerable extent upon the use of the radiator (see above) shown in the figure (compare Hillebrand, Bull. No. 422, U.S. Geol. Survey, p. 31). R is of sheet iron, aluminium or nickel, 6—7 cm. high, 8 cm. diam. at top and 5 cm. at bottom. The base, B, of iron, nickel, or platinum, is attached to R by turning the cogs of B up and over those of R. A platinum triangle is inserted about 4 cm. from the base ; and an aluminium ring with an opening slightly larger than the underlying crucible is placed over the radiator to hasten evaporation.

For determining boric oxide in borosilicate glasses a modification of Wherry's method (this J., 1908, 1179) is used. 0·5 grm. of the glass is fused with sodium carbonate, the product treated with 20—30 c.c. of hot water, filtered, and the filtrate and washings treated with about 7 c.c. of concentrated hydrochloric acid in a 250 c.c. round-bottomed flask, and then Wherry's method followed, except that barium hydroxide is used in place of sodium hydroxide for the titration.—A. S.

PATENT.

Oven suitable for use in the manufacture of tiles, pottery, and analogous ware, and for other purposes. C. Dressler, Marlow. U.S. Pat. 1,116,036, Nov. 3, 1914. Date of appl., March 17, 1913.

SEE Eng. Pat. 8228 of 1912 ; this J., 1913, 792.—T. F. B.

IX.—BUILDING MATERIALS.

Portland cement raw materials from Naga, Cebu ; Efficiency of ——. W. C. Reibling and F. D. Reyes. Philippine J. Sci., 1914, 9, 127—148.

VARIOUS raw materials (especially coralline limestone and tuff) were found suitable for the manufacture of high-grade cement, comparatively rich in SiO_2 and poor in Al_2O_3, the best results being obtained with a hydraulic modulus, 2—2·3. The setting properties were easily controlled by adding a small proportion of plaster, but, with a low hydraulic modulus, the cements were apt to be very quick-setting. Satisfactory artificial Roman cement with a cementation index

$$\left(\frac{2{\cdot}8\times\%SiO_2+1{\cdot}1\times\%Al_2O_3+0{\cdot}7\times\%Fe_2O_3}{\%CaO+1{\cdot}4\times\%MgO}\right)$$

as high as 2·47 was prepared by burning mixtures of calcareous and silicious materials in a rotary kiln at about 1000° C.—F. SODN.

Portland cement raw materials at Naga, Cebu ; Geology and field relations of ——. W. E. Pratt. Philippine J. Sci., 1914, 9, 151—160.

EASE of quarrying and transport combine to render the materials referred to in the preceding abstract desirable for cement manufacture in the Philippines. An ample supply of each is available.—F. SODN.

Natural cement versus brick ; Iwahig Penal Colony raw materials. W. C. Reibling Philippine J. Sci., 1914, 9, 163—173.

FINE-GRAINED coral sand was utilised with the local clay for the artificial preparation of natural (Roman) cement, the mixture being pugged with water to a stiff mud, moulded into bricks, and burnt at about 1000° C. The product, for most purposes, proved as good as or superior to brick made from the same clay, and the manufacture of a similar cement from other fine-ground calcareous sand is advocated, the application of existing brick presses and kilns being suggested ; a temperature of 1000° C., maintained for 3—4 hours is sufficient, and the clinker is readily ground. The advantage of mixing natural cement with a small proportion of Portland cement is pointed out.

Building stone ; Porosity of ——. D. G. Campbell. School of Mines Quart., 1914, 35, 242—246.

THE least porous rocks form the strongest and most durable building stones ; the porosity of granites and gneisses is less than 1%, that of limestones up to 10%, and of sandstones up to 20%. Unseasoned stones having large pores (*e.g.*, sandstones) are less affected by freezing than those having sub-capillary pores. The seepage of water through porous rock usually results in the solution of any colour-forming impurities and re-deposition of the latter upon the surface of the stone. By exposure to running water or water under pressure, porous stone containing calcareous ingredients soon becomes honeycombed and disintegrated. Owing to slow alteration by oxidation and hydration, a large proportion of accessory minerals may prove a source of weakness in igneous rock.

PATENTS.

Cement ; Method of producing —— *from molten blast-furnace slag.* W. Lessing, Menzenberg, Assignor to Mittelrheinische Cement-Industrie G. m. b. H., Cologne, Germany. U.S. Pat. 1,115,321, Oct. 27, 1914 ; date of appl., Aug. 9, 1913.

BY means of a mechanical agitator, molten slag is projected, in a disintegrated condition, into a horizontal, rotary tube through which a current of air and steam is passed in the opposite direction ; the rotary tube may be cooled and the air used without steam.—W. E. F. P.

Fire-brick. C. Hidecker, San Anselmo, Assignor to Ione Fire Brick Co., San Francisco, Cal. U.S. Pat. 1,115,429, Oct. 27, 1914; date of appl., June 3, 1913.

The brick is composed of silicious material fusing at 2800° F. (1538° C.), 75; argillaceous material fusing at 2500° F. (1371° C.), 10; shale fusing at 2250° F. (1232° C.), 10; and "material which cannot be fused below 4000° F. (2204° C.)," 5%.—W. E. F. P

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Electrical resistance and critical ranges of ——. G. K. Burgess and I. N. Kellberg. J. Franklin Inst., 1914, **178,** 634—635.

The determination of the variation of the electrical resistance of pure iron over the range 0°—950° C. was made in terms of that of platinum, using a very sensitive Wheatstone bridge. No anomalies in the resistance were found below the A2 region, but at 757° C. there was a sharp cusp in the temperature coefficient. At Ac3, which was identical with Ar3 (894° C.), the resistance fell abruptly 0·005 of its value, recovering it within 25°. A2 was found to be a strictly reversible transformation, whilst the A3 transformation took place at a higher temperature on heating than on cooling (see also this J., 1913, 1070).
—W. F. F.

Cast-iron; Some notes on the heat treatment of ——. R. Carrick. Proc. British Foundrymen's Assoc., 1913—1914, 196—208.

The term "heat treatment" is here applied collectively to those conditions brought about by the melting, casting, solidification, and the cooling subsequent to solidification, of a metal or alloy. The physical condition of cast-iron is largely controlled by the time taken for the solidification of the molten metal after pouring. By causing the iron to solidify quickly, a finer-grained, more homogeneous casting is obtained. This may be brought about by the use of "denseners" (chills). These must however be removed at the proper time to avoid chilling the solidified metal and so rendering it too hard to be machined.—T. St.

Malleable-iron castings. H. Ford. Proc. British Foundrymen's Assoc., 1913—1914, 173—180.

White pig-iron is employed. *Silicon* is the most active agent in a malleable iron mixing. A content of 0·35% will give white castings up to 2 in. thick, if cast hot enough. With Si 1%, the other ingredients being normal, anything thicker than about 0·5 in. would probably be grey. *Manganese* should be between 0·5 and 0·6% in the pig-iron. A considerable amount is burnt off in melting, but too much manganese causes hardness, and trouble in annealing. The malleable iron should contain 0·15 to 0·30%. *Sulphur* should be between 0·02 and 0·07%. High sulphur weakens the iron so that it is unable to resist the internal strains always present in hard castings, with the result that cracked castings are produced. *Phosphorus* should be below 0·25%, or cracked and warped castings will result. *Combined carbon* should be between 1·5 and 4·2%. If below 1·5% the casting will not anneal. *Graphitic carbon* is undesirable because it opens the structure and allows the oxidation to penetrate and weaken the iron in annealing. *Annealing.* Iron melted in a furnace is generally packed in puddler's scale (an iron silicate) and annealed at 1250°—1400° F. (676°—760° C.). Iron melted in a cupola is packed in pulverised hæmatite ore and annealed at 1600°—1800° F. (871°—982° C.). During annealing the combined carbon is almost entirely converted into "temper" carbon, with the result that the hard, brittle casting, having a distinctly white fracture, is changed so that it can be twisted, bent, and hammered hot or cold, without injury. The strength of the casting is greatly increased, being in some cases more than doubled. In American practice annealing is stopped when the carbon conversion has taken place, but the European practice is to continue annealing until carbon is actually removed to a depth of about ½ inch.—T. St.

Steel castings; The annealing of ——. A. T. Adam. Proc. British Foundrymen's Assoc., 1913—1914, 218—225.

Test-pieces of the same steel were annealed at the same temperature for varying lengths of time, all other factors being as far as possible identical. Annealing for a prolonged period allowed of the temperature being lowered, so that not only was the structure of the casting thereby rendered more homogeneous, but the risk of overheating was considerably reduced. Castings which had been annealed at a high temperature acquired a finer and more homogeneous structure when re-annealed at a temperature slightly above the lower recalescence point A2, and maintained at that temperature for a period equivalent to two hours in the case of a small test-bar.—T. St.

Steel and cast-iron bars broken at different temperatures; Physical properties of ——. H. Perrine and C. B. Spencer. School of Mines Quart., 1914, **35,** 194—212.

A Rhielé machine of 100,000 lb. capacity was used for testing the specimens, each of which was heated electrically (in a platinum-wound, porcelain tube) while in position. The following results were obtained, E being the elongation, R the reduction of area, and U the ultimate strength—

It is suggested that the strength of steel is dependent on its "fibrous character," the term "fibrous" being used in contradistinction to "granular," as applied to cast iron and not taken too literally. When heated to 500° F. (260° C.) the fibres change their relative positions temporarily, so that if the hot bar be broken, increased strength is exhibited; but on cooling, the fibres return to their original position. The same action takes place at above 500° F. (260° C.), but is offset by the weakening effect of the repulsive action of heat on the molecules. The more fibrous the character of the metal, the greater the action of heat in increasing its strength.—W. E. F. P.

[*Steel.*] *Martensite structure; Note on crystal twinning and the* ——. C. H. Desch. Faraday Soc., Nov., 1914. [Advance proof.]

By slowly cooling an overheated steel (C 0·28%) a martensitic structure was obtained without increase of hardness; by examination with an immersion objective, the whole mass was found to consist of pearlite packed closely in some parts and loosely in others. The view of Edwards and Carpenter (this J., 1914, 552) that martensite and austenite are constitutionally identical, the former being repeatedly twinned, and its hardness due to the formation of amorphous material at the surfaces of slip on which twinning occurs—is rejected and it is considered that the martensitic structure is an accompaniment, and not the cause, of the hardness of a quenched steel, martensite being so much harder than its components as to suggest the presence of a solid solution.—W. E. F. P.

Steels; The part played by the amorphous phase in the hardening of ——. J. C. W. Humfrey. Faraday Soc., Nov., 1914. [Advance proof.]

The formation of the hard, amorphous solution of α-iron and iron carbide (comparable with Beilby's amorphous phase formed by overstrain) to which the hardness of quenched carbon-, or normally cooled alloy-steels is due, is explained on the assumption that in the passage of a substance from one allotropic modification to another of different crystalline form, as at the Ar_3 point in steels, a temporary amorphous phase is produced corresponding to the liquid phase of the modification about to be formed; and that owing to sudden cooling or the presence of certain alloyed elements, whereby the change point is lowered to a temperature at which crystallisation in the viscous mass becomes difficult, the amorphous phase is retained in a metastable form in the cold.—W. E. F. P.

Gold proof plate; Preparation of a fine ——, *by chlorine gas.* Memorandum by the Assayers of the Melbourne Mint. Ann. Rep. Mint, 1913, 138—140.

Cornets of gold, derived from the metal obtained by reduction with sulphurous acid, and containing 0·1% of impurity (chiefly Ag), were treated with cold *aqua regia* (4 : 1), the solution largely diluted and allowed to stand for a week to effect separation of silver chloride. Three successive quantities of a dilute solution of silver nitrate (containing Ag 0·5 grain) were then added at intervals of 3 days, the surface of the liquid being gently stirred after each addition, and the whole was allowed to stand for 14 days. Any iridium or other impurity suspended in the liquid was entangled in the precipitated silver chloride; the clear solution was siphoned off, evaporated to dryness and ignited in porcelain; the sponge gold fused in a clay crucible with potassium bisulphate and nitrate, borax added, the melt allowed to cool, the cone of gold treated with boiling hydrochloric acid to remove adhering slag, placed by hand upon borax-glass contained in a clay crucible within a large, covered guard-pot, and melted under conditions precluding contamination of the metal by furnace dust. A slow current of chlorine was then passed through the molten metal for 1 hour, the gas being conducted through a clay tube (½ in. bore) by which the gold was continuously stirred. The charge was allowed to cool in the crucible, the cone of gold treated with boiling hydrochloric acid and finally rolled (with special precautions against contamination) into a fillet which was also treated with boiling acid. The original gold weighed 21·5 oz., the finished fillet 21·28 oz., and 0·204 oz. was subsequently recovered from the slag. The fineness of the metal, as determined by the assay of 20 samples taken along the fillet, was higher than that of the Board of Trade 1899 fine gold proof plate (999·98).—W. E. F. P.

Gold; Annealing of ——. Memorandum by T. K. Rose. Ann. Rep. Mint, 1913, 55—56. (See also this J., 1913, 869.)

Pure gold is softened by heating for 30 mins. at 130° C.; re-melting in air causes a slight reduction of the annealing temperature, although no change in the purity of the gold can be detected by assay; after re-melting in hydrogen, of which the metal absorbs 0·002%, gold is not completely softened by heating for 30 mins. at 300° C. Other impurities have similar but less marked effects: *e.g.*, the annealing temperature of gold containing Ag 0·05% is 225° C. The relative purity of two samples of "proof" gold is more readily determined by heating hard-rolled test-pieces for 30 mins. at 130°—150° C. and testing the degree of softening, than by the ordinary methods of assay; the heated specimens are tested in a machine for measuring hardness; or by immersion for an hour in cold dilute *aqua regia* (1 : 1) when the softened metal becomes recrystallised while the structure of the less pure (hard) gold remains unchanged. As shown by microscopical examination of specimens of gold in various stages of annealing, recrystallisation (softening) begins and finishes in particular laminæ or flattened crystals, other laminæ or crystals remaining unchanged until more time has elapsed or the temperature has been raised; hence, partly-annealed gold is composed of alternate bands of hard and soft material, and has weak places where its rigidity and resistance to rupture are little higher than those of the fully-annealed metal.—W. E. F. P.

Nickel and nickel-bronze coinages of the world (*to the end of* 1912). Ann. Rep. Mint, 1913, 90—93.

Of 895,920,035 nickel coins in circulation at the end of 1912, 62·5% were in use in Austria-Hungary; 17·2% in France and Turkey; 16·9% in Germany, Italy and Switzerland; and 3·4% in Mexico, Montenegro, Danish West Indies, and Zanzibar. In Austria-Hungary, nickel has been coined and issued regularly since 1892; in France, it was adopted, for 25-centime coins only, in 1903, but by a new law passed in Aug. 1913, these coins and the present bronze currency are to be withdrawn and gradually replaced (over a period of 10 years) by 780,000,000 coins (25, 10 and 5 centimes) of pure nickel; in Turkey, nickel coinage was introduced in 1911. Of 4,136,851,348 nickel-bronze (Ni 25, Cu 75%) coins in circulation at the end of 1912, 31·4% were in use in British Colonies, Belgium and United States; 37·6% in Germany and Switzerland; and 31·0% in 34 other countries including Holland, Greece, Portugal, Egypt, Persia, Japan, Siam, Korea, most of the South and Central American States, some of the smaller European States, parts of East and Central Africa, etc. Practically all the nickel-bronze coins struck for British Colonies have been issued since 1907; and the alloy was first adopted by Belgium in 1861.—W. E. F. P.

Metal melting at the Royal Mint; Comparative costs of ——, *with coal-gas and coke fuel.* Memorandum by E. Rigg. Ann. Rep. Mint, 1913, 34—35.

The following table shows the saving (27·3%) effected by the substitution of coal-gas for coke fuel in the melting houses of the Royal Mint, London; the results for the two years are comparable since the proportion of nickel-bronze melted (requiring a higher temperature than gold and silver) was about the same (55—56%) in each.

Year.	Weight of good bars cast (tons).	Rate per ton (shillings).			
		Fuel.	Crucibles.	Wages.	Total.
1909 (coke)	1197·7	24·29	42·09	15·68	82·06
1913 (coal-gas)	1957·9	22·09	26·69	10·84	59·62

The daily output per furnace was greater in 1913 than in 1909, the percentage increases for gold, silver, bronze and nickel-bronze being 88·5, 124·5, 157·7 and 161·1, respectively; and the amount of "sweep" produced was much less.—W. E. F. P.

Copper products; Leaching —— at the Steptoe (U.S.A.) works. W. L. Austin. Min. and Eng. World, **41**, 806.

The dust from roasting-furnace dust chambers is treated, together with a silicious oxidised ore, to obviate the smelting of low-grade silicious flue dust. The greater portion of the copper in the chamber dust is soluble in water, and, when mixed with water, contains sufficient acid for lixiviating the silicious ore. The chamber dust, after treatment with water, is settled in vats, and the clear liquid is percolated through the silicious ore in wooden vats with a filter bottom, the liquid being finally treated with scrap iron in precipitating boxes.—B. N.

Cathode copper; Impurities in ——. L. Addicks. Met. and Chem. Eng., 1914, **12**, 706—708.

The impurities in cathode copper may have been directly deposited or may be derived from anode slime or included electrolyte. Plotted results show a straight line relation between fouling by nickel and arsenic and content of these elements in the electrolyte. The curve shows that in the case of nickel there is no fouling from anode slime. The large content of nickel in cathode copper suggests fouling by electrodeposition in addition to included electrolyte. Fouling by silver and gold should be directly proportional to the content in the anodes, as all the silver and gold in the anodes enters the slimes.—W. F. B.

Copper; Absorption of gases by refined ——. W. Stahl. Metall und Erz, 1914, **11**, 470—482.

The gas-absorbing power of molten copper increases in general with the temperature up to a certain point, also with increasing purity of the metal, and with the partial pressure of the gas; the presence of Pt or Ni, however, has a favourable influence on the absorption.

Sulphur dioxide. The disintegration of copper which takes place during solidification has been traced to occluded SO_2, which is formed by oxidation of the sulphur present, and given up during solidification with a "spitting" action. Up to 1500°, the absorption increases almost linearly with the temperature, and approximately as the square root of the pressure. The fact that the gas causes the metal to "spit" and become spongy during solidification, and that a considerable quantity of gas is still retained in the cold metal, shows that absorption and not adsorption effects are concerned. SO_2 does not diffuse through solid copper below 1000° C. The interaction of cuprous oxide and sulphide, giving copper and sulphur dioxide, is exothermic; the reverse reaction can be expressed as $Cu_2S+2Cu_2O=6Cu+SO_2$—38,000 cals. It follows from this that an equilibrium relation will be obtained. Estimations of the lowering of freezing point produced by the oxide and sulphide show that the compounds occur as Cu_2S and Cu_2O, and that their solubilities are more than sufficient to account for the absorption of SO_2 by decomposition and chemical reaction. The fact that the addition of either Cu_2S or Cu_2O to the system diminishes the solubility of the gas, is also in accord with this view. That a state of equilibrium between the four participating bodies occurs at all temperatures has been verified in a number of investigations.

Hydrogen. Evidence of the solubility of hydrogen is given by the surface disintegration and blister-like structure assumed by the metal during solidification after exposure to this gas. An absorption of H_2 in, and diffusion through copper has been detected at 650° C. Up to 1500° C., the absorption increases almost linearly with the temperature, except at the melting point of the metal, when a sudden increase occurs. At 650° the solubility is 0·1 and at 1500° C., 1·4 mgrms. H_2 per 100 grms. of copper. With both the molten and solid metal, the solubility increases as the square root of the pressure. The conductivity of copper is not affected by dissolved hydrogen. On heating copper containing oxide in a hydrogen atmosphere, the gas penetrates the metal and reduces the oxide with formation of water, which escapes by disintegrating the metal and rendering it unsuitable for further mechanical working. A reaction of this nature takes place in molten copper during the "poling" treatment.

Hydrocarbons are decomposed by molten copper into carbon and hydrogen, of which the former is oxidised and the latter absorbed. No occlusion of any undecomposed hydrocarbon has been observed.

Oxygen. The dissociation pressure of cuprous oxide equals the partial pressure of atmospheric oxygen, or 0·21 atm., at 1662° C. When in solution in the copper, the dissociation pressure is lowered, so that, at 1600° C., it is certain that no thermal decomposition of the dissolved oxide occurs, and the absorption of O_2 at this temperature is not a physical solution but a chemical combination.

Water, carbon dioxide, nitrogen, argon, helium. No absorption of any of these gases in either solid or liquid copper can be detected.

Carbon monoxide. A slight solubility of this gas in copper has been shown by changes in the density produced in the metal by its presence, by the blister-like structure it imparts to the metal, by spectrum analysis, and by direct measurement. At 1420°, 61 grms. of Cu absorb 0·15 c.c. CO. This small quantity of gas appears to have a marked influence on the physical properties of the refined metal.

The above data indicate that during the refining of molten copper, the absorption of CO predominates during the end of the "hard poling" period, and at the beginning of the "green poling," while the absorption of H_2 predominates during the latter period when the oxygen has been removed.—J. N. P.

Lead ores; Smelting —— in the blast-furnace. I. A. Palmer. Mining and Eng. World, Oct. 24, 1914, 755—759.

In modern smelting practice, the pre-roasting of the ore and sintering are accomplished in one operation. Oxidised fines, silicious sulphides, concentrates, and slimes may be mixed and sintered together with the ore, but flue-dust can only be satisfactorily treated after briquetting. One of the most serious objections to fines in the blast-furnace is that irregularities in the formation of slag and matte occur, and these lead to metal losses. All the constituents of the charge should be well mixed and arrive at the fusion zone of the furnace at approximately the same time, and materials of very different composition should not be used, as the influence of inequalities in distribution is then accentuated. In roasting ores, iron sulphide is the first, and zinc and lead sulphides are the last to be oxidised. On treatment in the blast-furnace, zinc sulphide, which does not mix in all proportions with the other sulphides, separates, when present in considerable quantity, and floats on the top of the matte, forming a pasty scum which prevents a good separation of matte and slag. Laboratory experiments have shown that slags consist of a mixture of constituents, and large variations in the proportion of these constituents do not materially affect the fusibility or fluidity. As a result of improved methods of preparing the charge higher temperatures can now be used in smelting, and hence, without diminishing the fluidity, larger quantities of lime can be introduced and more basic and more refractory slags can be produced. The minimum quantity of coke required is that corresponding to 10% pure carbon of the weight of material (less slag and fuel); often it is necessary to use 12%. The blast-pressure used in the larger plants is 30 to 40 oz. per sq. inch. The loss of lead through volatilisation is apt to be large and overlooked. The sulphides of the heavy metals cannot be completely separated from the slags, on account of the slightly solvent action of the latter on the former.—J. N. P.

Lead; Electrodeposition of ——. F. C. Mathers and B. W. Cockrum. Met. and Chem. Eng., 1914, **12**, 714—715.

To obtain smooth finely crystalline deposits there is added to the bath an "addition agent" prepared by shaking 12·5 grms. of aloes with 500 c.c. of warm water, separating the solution and dissolving the insoluble tar or gum in 25—50 c.c. of glacial acetic acid. This acid solution is added to the bath, which should contain 100 grms. of lead acetate and 40 grms. of ammonium perchlorate per litre. A current density of 3·6 amp. per sq. ft. for thick deposits and 7·2 amp. per sq. ft. for thin may be used. With lead lactate and lead formate solutions, the baths should contain 4% of lead as lactate or 2% as lead formate, 1—5% of lactic or formic acid, 4% of ammonium perchlorate and 0·25% Barbadoes aloes, the mixture being warmed and filtered before use. A current density of 3·6 amp. per sq. ft. may be used. Sodium naphthalenesulfonate may be used instead of the ammonium perchlorate. (See also this J., 1913, 429; 1914, 358).—W. F. B.

Aluminium-magnesium alloys; Supplement to the phase diagram of ——. H. Schirmeister. Metall und Erz, 1914, **11**, 522—523. (See also Grube, Z. anorg. Chem., 1905, **45**, 225.)

The alloys (200 grms. in each case) were melted in a nickel wire electric furnace, and the progress of the cooling registered by means of a thermo-element and recording galvanometer. The first stationary points were found at temperatures which gradually fell from 657° to 550° C., as Mg increased from 0 to 20%. Second stationary points, denoting a eutectic, were found at 580°—590° C. with alloys of between 2 and 15% Mg, and a second similar eutectic point was found at 455° C., with alloys containing between 12 and 15% Mg.—J. N. P.

Calorizing. Coating metals with a layer of aluminium alloy for protection against high temperatures. H. B. C. Allison and L. A. Hawkins. Met. and Chem. Eng., 1914, **12**, 730.

The metal to be coated is heated in a revolving drum with substances containing *inter alia* finely ground aluminium, or it is packed in or painted with a suitable mixture containing aluminium and heated. Calorized iron tubes withstand oxidation at 900°—1000° C. With copper the calorizing is effective against oxidation at low and high temperatures. The effect of calorizing on the electrical resistance and temperature coefficient of iron is shown in the table. No. 1 had a lighter calorizing coat than No. 2.

Samples.	Electrical resistance, ohms per m. (19°).	Temp. coeff. (0°—150°) × 10^{-8}.
Iron ribbon	0·905	5·61
do. calorized No. 1	2·45	1·72
do. calorized No. 2	7·6	0·151

—W. F. B.

Metals; The influence of allotropy on the metastability of ——*, and its bearing on chemistry, physics and technology.* E. Cohen. Faraday Soc., Nov. 23, 1914. (See also this J., 1908, 1155; 1909, 1139; 1910, 94, 281; 1914, 597).

Experiments made with pure cadmium are described, measurements being made with the pyknometer, the dilatometer, and with low voltage standard cells in which the negative electrode consisted of cadmium deposited electrolytically on a platinum spiral. The results show that ordinary cadmium contains three allotropic forms. Density and dilatometric measurements made with pure lead indicated for this metal also the simultaneous presence of more than two allotropic forms. The conclusion is drawn that the pure metals (Cd, Pb, Bi, Cu, Zn, Sb) as known until now, are metastable systems consisting of two (or more) allotropic forms. This is a consequence of the very strongly marked retardation which accompanies the reversible change of these allotropic modifications below and above their transition-points. All the physical and mechanical constants of metals hitherto determined thus refer to complicated metastable systems, which are entirely undefined, as the quantities of the α, β, and γ modifications they contain are not known. The reversible transformations of one modification to another must play an important rôle when metals are subjected to changes of temperature. If the metals are in contact with electrolytes (water), the transformation velocity is enormously accelerated, and the volume changes which generally accompany these transformations may cause the disintegration of the metals. These phenomena must be taken into account in cases where corrosion occurs.—T. St.

Hardness [of metals]; Interstrain theory of ——. A. McCance. Faraday Society, Nov., 1911. [Advance proof.]

Pure iron, like other metals, is hardened when strained so as to cause permanent deformation. The iron is then in a condition of "interstrain," in which the arrangement of the atoms in the original crystalline structure is so far disturbed that the atoms can no longer return to their positions of equilibrium, and it is this condition whch is considered to involve increased hardness. Under strain, α-iron remains magnetic, and γ-iron non-magnetic, showing that the metal is not merely reduced to an amorphous structure by strain, but retains the distinguishing properties which are the result of crystalline form. To harden steel by quenching, it must be heated to the temperature at which the carbon is all in solution, and the greatest hardness is obtained when the temperature reaches the highest change-point. The maximum hardness is obtained with C 0·7%: since the hardness is not proportional to the amount of carbon dissolved, the action of the carbon is indirect. Steel which is non-magnetic at the temperature of quenching becomes magnetic in the hardened state, owing to the conversion of γ- into α-iron. With a given rate of cooling this change of crystalline structure stops at a point determined by the increase in the internal viscosity at the lower temperature and in this way a condition of interstrain is produced involving increased hardness. Tempering removes the condition of interstrain.—A. T. L.

Acetylene in welding and cutting; Precautions in using ——. Karbid u. Azetylen, 1913, 255—260; J. Gasbeleucht., 1914, 57, 306.

The use of an efficient water-trap, to prevent oxygen from entering the acetylene pipe or container either by stopping it or discharging it to the atmosphere, is a sufficient safeguard in practice. Vessels packed with sand or wire gauze uselessly complicate the apparatus and only arrest the explosion of mixtures poor in oxygen.—O. E. M.

Welding; Electropercussive ——. C. E. Skinner and L. W. Chubb. Met. and Chem. Eng., 1914, 12, 713—714.

Wires are welded together by means of electrical discharges from a condenser directed across their ends as they are being mechanically pressed together. Any combination of metals can be welded by these means, but joints of, for example, Al and Sn or Pb and Fe are not permanent.—W. F. B.

Plaster-of-Paris in foundry work. C. Heggie. Proc. British Foundrymen's Assoc., 1913—1914, 95—119.

The possibilities of plaster-of-Paris for making patterns for foundry work are stated to be unappreciated both in this country and in America. The methods of mixing the plaster and its formation into patterns are discussed, and the preparation of various patterns is described in detail.—T. St.

Flotation; An experimental contribution to the study of ——. H. Schranz. Metall und Erz, 1914, 11, 462—470.

The floating of small particles is determined by the angle, at the point of contact of liquid, air, and solid, between the submerged surface of the particle and the tangent to the surface of curvature of the liquid assumed at this point through surface tension forces; the size and the curvature of the surface bounding the particle, the specific gravity, and the volume of the particle. The buoyancy of zinc blende on water was unaffected by the addition of sulphuric acid, but that of galena diminished with increasing concentration of the acid. This is attributed to the difference in solubility of the sulphates of the respective metals, whereby the nature of the surface is unchanged or modified in the two cases. Surface impurities of all kinds affected to a high degree the floating power. In many cases, physical changes produced by heating or by exposing to air determined largely the boundary angle and the ability to float. The nature of the fracture of the particle, *i.e.*, whether the surface was bright or rough, also had some influence.—J. N. P.

Minerals; New results with the microscopical investigation of opaque ——. O. Stutzer. Metall und Erz, 1914, **11**, 450—455.

The microscopical examination of opaque minerals by means of reflected light has been applied in petrography to an increasing extent for the purpose of identifying mineral composition, and for the examination of the constituents of crude ores. Chalcopyrite, iron pyrites, pyrrhotite, magnetite, and some other minerals which occur in rocks can usually be detected on a polished section of a fragment of the ore by means of the colour. If the polished section be etched, similarly coloured minerals often show other very marked differences. Constituents which are unattacked by the etching agent retain their polish and stand in relief. The characteristics in the microstructure of native platinum, osmiridium, and nickeliferous pyrrhotite are pointed out. In the last case, the nickel was seen to be associated mechanically with the pyrrhotite in the form of pentlandite, whereas formerly it was considered to be in chemical combination in the molecules of the pyrrhotite. In titaniferous magnetite, microstructural examination shows that the titanium occurs partly in mechanical association with the magnetite as ilmenite, and in part replaces the iron chemically in the magnetite molecules. The structure of the magnetite-ilmenite mixture is ascertained by etching with hydrochloric acid, when magnetite dissolves, whilst ilmenite is not attacked. In copper-iron pyrites bornite, $3Cu_2S,Fe_2S_3$, copper glance, Cu_2S, chalcopyrite, $CuFeS_2$, enargite, Cu_3AsS_4, and iron pyrites, FeS_2, can be identified by their microstructure. In low-grade copper ores, the metal appears not to occur in chemical combination with the pyrites molecule, but to be mechanically associated in the form of the known copper minerals.—J. N. P.

Smoke from metallurgical furnaces; Recent progress in the abatement of ——. C. Schiffner. Metall u. Erz, 1914, **11**, 257—278.

The sulphur dioxide produced in roasting sulphide ores is reduced to sulphur, in Young's "Thiogen" process (this J., 1913, 293), by a flame of hydrocarbon in sufficient excess over that required to deal with the free oxygen; BaS or CaS is used as catalyst. Hall's process consists in roasting in an atmosphere containing insufficient oxygen to oxidise the sulphur. In Cottrell's process (this J., 1911, 1037; 1914, 1054) suspended matter is removed by passing the gases between electrodes at a tension of 17,000 to 40,000 volts; sulphur dioxide is removed by converting the gases into a mist by a water spray or other means. Püning (Ger. Pat. 262,882) uses the water spray as the positive electrode. Small scale researches, described in detail, show that with simple apparatus it is impossible to obtain a mist capable of absorbing all the sulphur dioxide in flue gases, but that by blowing in steam and cooling, or by mechanical spraying, this result might be attained.

Working and health conditions of lead and zinc smelters in Germany. See XIXb.

Determination of uranium. Schlundt. *See* XXIII.

Patents.

Iron or steel; Prevention of oxidation or rusting of ——. F. R. G. Richards, Warwick, and M. A. Adam, London. Eng. Pat. 25,134, Nov. 4, 1913.

The iron or steel article (*e.g.*, cycle tubing) is immersed for 2—20 mins. in a solution prepared by dissolving manganous carbonate (1¾ lb.) in a boiling mixture of phosphoric acid, B.P. (60 fl. oz.) and water (87 fl. oz.).—W. E. F. P.

Iron, steel, and cast iron; Impregnation of —— *with nickel.* A. C. Hyde, London. Eng. Pat. 26,712, Nov. 20, 1913.

Articles of iron, steel, or cast iron are heated at 500°—1000° C. in a gas containing carbon monoxide which has been passed over nickel or nickel oxide below a red heat, or are heated in powdered nickel or nickel oxide in an atmosphere of carbon monoxide or hydrogen for 2 hours at 500°—1000° C.—O. E. M.

[Iron, steel, etc.] Clad metals; Method of making ——. J. F. Monnot, Paris, Assignor to Duplex Metals Co., New York. U.S. Pat. 1,114,792, Oct. 27, 1914; date of appl., Apr. 2, 1910.

To plate iron, steel, or other metal, it is cleaned, coated with a suitable alkali solution and then with a metal or alloy of lower m. pt. in a highly heated condition; after which the desired metal is applied in molten form.
—W. E. F. P.

Steel or iron sheets; Oxidising ——. J. E. Carnahan and A. J. Maskrey, Canton, Ohio. U.S. Pat. 1,115,281, Oct. 27, 1914; date of appl., June 11, 1913.

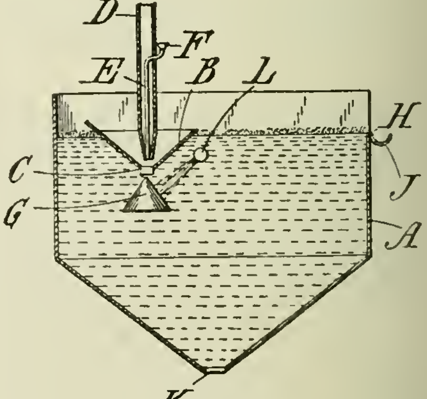
Sheets in packs are heated in a sand-sealed protecting box within a sand-sealed annealing box and then separately exposed to an oxidising agent.—O. E. M.

Ore concentration; Apparatus for ——. A. H. Higgins, W. W. Stenning, and Minerals Separation Ltd., London. Eng. Pat. 21,650, Sept. 25, 1913.

An apparatus for concentrating ores by gaseous flotation of certain mineral particles in liquid, consisting of a series of contiguous, rectangular vessels each having an inlet for ore-pulp; an outlet for residues; near the bottom, an inlet for air or other gas and means for producing a zone of violent agitation and aeration; and, near the top, for producing a comparatively quiet zone where the mineral froth collects and is separated.—W. E. F. P.

Ores; Method and apparatus for concentrating ——. Minerals Separation Ltd., London. From G. E. Öhrn, Stockholm. Eng. Pat. 22,346, Oct. 3, 1913.

The powdered ore, or pulp, is mixed with a minute quantity of a mineral frothing agent and subjected to the action of a steam jet directed on to the surface of water. A spitzkasten, A, (fig.) has a hopper, B, having an outlet, C, below the water-level, a steam-pipe, D, being arranged in the hopper so as to form an injector. Within the steam-pipe is a tube, E, having an external



funnel, F, through which the frothing agent is supplied; and under the outlet, C, a cone, G, is centrally disposed. The spitzkasten has an overflow lip, H, a launder, J, and an outlet, K, for the tailings; and a water-spray, L, is arranged under the surface of the water in the spitzkasten so that streams of water are directed on the froth as the latter rises to the surface.—W. E. F. P.

[*Copper, iron, etc.*] *Metals; Method of and means for producing and refining* ——. S. B. Frumkin, Minsk, Russia. Eng. Pat. 22,834, Oct. 9, 1913.

The ore is reduced, and/or the metal melted, without flux, in a closed, invertible, horizontal, annular furnace-chamber into which a blast of air, with or without heating gases, is passed tangentially from a horizontal, tubular regenerator; the inlet and outlet of the chamber are close together and communicate with the regenerator by means of a common, funnel-shaped member. The chamber is then inverted and the blowing continued, the molten metal being further heated by contact with the refractory lining of the roof, and finally discharged by tilting the apparatus.—W. E. F. P.

[*Copper.*] *Metals; Chemical concentration of* ——. C. S. Bradley, New York. U.S. Pat. 1,114,726, Oct. 27, 1914; date of appl., Feb. 27, 1913.

Ore containing cupric oxide is treated with an aqueous solution of sulphur dioxide and calcium chloride to produce a solution of cuprous chloride.—W. E. F. P.

Salt bath furnaces [*for heating or tempering metals*]. S. N. and E. R. Brayshaw, Manchester. Eng. Pat. 28,097, Dec. 6, 1913.

A salt bath furnace for high-speed steels having a combustion chamber wider at the bottom than at the top and a burner the flame of which enters tangentially and is guided by baffles completely round the melting-pot. —O. E. M.

Aluminium alloy. W. A. McAdams, Bayshore, N.Y., U.S.A. Eng. Pat. 4779, Feb. 24, 1914.

An alloy of Al 100, Ag 15, Cd 10, and Ti 3, parts by weight.—W. E. F. P

Metal alloy. E. Smith, London. U.S. Pat. 1,114,055, Oct. 20, 1914; date of appl., Jan. 30, 1914.

An alloy of Cu 40, Ni 8·5, Zn 5, Sn 2·5 and Pb 1 (parts by weight), prepared by melting the granulated nickel with "a flux of silica," adding half the copper gradually, with stirring, and the remainder in bulk, then the zinc, and finally the tin and lead together.—W. E. F. P.

Alloy. S. W. Parr, Urbana, Ill. U.S. Pat. 1,115,239, Oct. 27, 1914; date of appl., Feb. 27, 1914.

A corrosion-resisting alloy, of high electrical resistance, composed of Ni 63, Cu 5, metals of the Cr-group 27% (*e.g.*, Cr 20, Mo 5, and W 2%) with less than 2% each of Al, Mn, and B as deoxidisers. In the unworked condition it has a tensile strength of 60,000 lb. per sq. in.—O. E. M.

Briquette composition and process of making [*ore*] *briquettes.* E. A. Paterson, Port Arthur, Ontario, Canada. U.S. Pat. 1,111,919, Sept. 29, 1914; date of appl., Dec. 26, 1913.

A silicious ore, such as iron ore, is agglomerated with a mixture of alkali silicate and alkaline-earth carbonate *e.g.*, hydrous sodium silicate and limestone). The powdered ore is preferably discharged as a layer upon a suitable surface, a mixture of ore dust with hydrous alkali silicate solution and water discharged upon this layer, the mixture moulded and dried upon the same surface, and the briquettes finally discharged, adhering particles of ore being removed. The quantity of carbonate should be proportioned to the total silicic acid in the finished briquettes, and these may be hardened by exposure to carbon dioxide.—F. Sodn.

Ore-roaster. G. H. Dern, Salt Lake City, and T. P. Holt, Park City, Utah. U.S. Pats. 1,113,961 and 1,113,962, Oct. 20, 1914; date of appl., April 9, 1914.

A column of ore is roasted "by internal combustion" in a vertical chamber having a crushing grate (for supporting and disintegrating the charge) beneath which is situated an air-pressure chamber, of inverted conical shape, which also serves as a receptacle for the roasted product. —W. E. F. P.

Roasting-furnace. F. Laist, Anaconda, Mont. U.S. Pat. 1,114,371, Oct. 20, 1914; date of appl., Oct. 15, 1913.

Between two of the hearths of a furnace of the superposed-chamber type is a combustion chamber having, on opposite sides, horizontal inlets for furnace gases and, at the bottom, a series of vertical openings disposed radially, and communicating with the lower hearth; from the latter the gases pass outwards and thence to the upper hearth.—W. E. F. P.

Ores; Process of roasting ——. F. Laist, Anaconda, Mont. U.S. Pat. 1,114,372, Oct. 20, 1914; date of appl., Nov. 22, 1913.

In an apparatus of the superposed-chamber type, the ore, after being heated at a high temperature by furnace gases, is removed to a zone of comparatively low temperature while still in contact with the gases, and thence to a heat-insulated chamber where it is mixed with salt and the process concluded without further heating. —W. E. F. P.

Furnace; Metallurgical ——. U. Wedge, Ardmore, Pa. U.S. Pat. 1,115,263, Oct. 27, 1914; date of appl., Feb. 25, 1913.

Rotating hearths attached to a central vertical shaft alternate vertically with fixed hearths attached to an outer casing. Rabbles fixed to the under side of each hearth rake the one below.—O. E. M.

Detinning; Process of ——. J. Weber, Essen-on-the-Ruhr, Germany. U.S. Pat. 1,115,262, Oct. 27, 1914; date of appl., Jan. 31, 1912.

Tinned iron is treated with a current of chlorine above the temperature at which iron is attacked; the chlorine is passed through a cooler to remove the heat of reaction. —O. E. M.

Metals from ores; Process for separating ——. H. A. Wagner, East Orange, N.J. U.S. Pat. 1,115,351, Oct. 27, 1914; date of appl., Jan. 27, 1914.

Copper, zinc, and similar metals are separated by suspending their sulphide ores in the anode compartment of an electrolytic cell containing a solution of common salt; the anode and cathode are separated by a diaphragm and a depolariser is placed in the path of the current to prevent hydrogen from appearing in the anode compartment. —O. E. M.

Metal wires; Process for drawing or alloying ——. Wolfram Lampen A.-G. Ger. Pat. 276,894, April 16, 1913.

A lubricant for use in wire drawing consists of a suspension or solution of a metal which will alloy with the metal being drawn, or a suspension or solution of an alloy or compound of such a metal; the metal or metals constituting the lubricant are alloyed with the wire by heating during or after drawing. Gelatinous thorium compounds, such as the gelatinous hydroxide obtained by precipitating a thorium solution with a base, may be used in preparing wires of tungsten-thorium alloy, and vanadium hydroxide may be used in alloying iron wire with vanadium.—T. F. B.

Furnaces; Electric ——. F. J. Machalske, Plattsburg, N.Y., U.S.A. Eng. Pat. 15,455, June 27, 1914. Under Int. Conv., June 27, 1913.

See U.S. Pat. 1,099,559 of 1914; this J., 1914, 796.—T.F.B.

Electrodes for electric welding or soldering; Preparing ——. O. Kjellberg, Gottenborg, Sweden. U.S. Pat. 1,115,317, Oct. 27, 1914. Date of appl., Jan. 29, 1912.

See Eng. Pat. 3762 of 1911; this J., 1912, 590.—T. F. B.

Briquetting iron ores and the like; Method of ——. G. Crusius, Gross-Ilsede, Germany. U.S. Pat. 1,116,024, Nov. 3, 1914. Date of appl., Nov. 29, 1913.

See Eng. Pat. 27,538 of 1913; this J., 1914, 488.—T. F. B.

Hoppers for gas producers, blast furnaces, and the like. Eng. Pat. 23,054. *See* IIa.

Producing cement from blast-furnace slag. U.S. Pat. 1,115,321. *See* IX.

XI.—ELECTRO-CHEMISTRY.

Corrosive action of electric currents on gas and water mains. Herrmann. *See* IIa.

Patents.

Furnace; Electric ——. W. N. Crafts, Oberlin, Ohio. U.S. Pat. 1,114,733, Oct. 27, 1914. Date of appl., Nov. 28, 1911.

The furnace comprises a basin below which is a magnetic core and primary winding, together with an incomplete secondary having terminals at the bottom of the basin, and arranged so that the circuit is completed by the bath of material in the basin; the secondary is composed of material of relatively high conductivity which does not melt during the operation of the furnace.—T. F. B.

Electrode. R. L. Seabury, Lakewood, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,115,027, Oct. 27, 1914; date of appl., Aug. 2, 1911.

The electrode (for furnace use) consists of a carbon rod tightly enclosed in a carbon tube, the two parts being moulded under pressure, placed in position, and baked together.—W. E. F. P.

Electric arcs; Means for the production of long continuous ——. O. Schönherr, Christiania, and J. Hessberger, Christianssand, Assignors to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,115,249, Oct. 27, 1914. Date of appl., May 18, 1910.

See Fr. Pat. 410,710 of 1909; this J., 1910, 829.—T. F. B.

Electric discharges in gases; Method of producing continuous or constant ——. C. F. R. von Koch, Stockholm. U.S. Pat. 1,115,625, Nov. 3, 1914. Date of appl., March 20, 1911.

See Fr. Pat. 427,745 of 1911; this J., 1911, 1070.—T. F. B.

Apparatus for bleaching fabrics. Eng. Pat. 26,727. *See* VI.

XII.—FATS; OILS; WAXES.

Soap solutions; Effect of resene on the lathering power of ——. C. H. Herty and C. W. Williard. J. Ind. Eng. Chem., 1914, 6, 895—896.

Soap solutions to which a small quantity of resene (unsaponifiable constituents) from the oleoresin of *Pinus heterophylla* was added, formed less lather when shaken than similar solutions free from resene and the time required for the complete subsidence of the lather was considerably less when resene was present.—A. S.

Patents.

Oils and fats; Process of bleaching ——. C. Baskerville, New York. U.S. Pat. 1,114,095, Oct. 20, 1914; date of appl., Jan. 24, 1913.

The oils are treated with a mixture of an inorganic absorbent (*e.g.*, fuller's earth), and a fibrous organic absorbent (*e.g.*, cellulose), with or without an electrolyte such as sodium chloride.—C. A. M.

Oils and the like; Apparatus for treating [hydrogenating] ——. L. Mandelstam, New York. U.S. Pat. 1,114,623, Oct. 20, 1914; date of appl., Apr. 30, 1912. Renewed Mar. 13, 1913.

Catalytic hydrogenation of the oil is effected in a closed vessel containing a steam coil and provided with means for spraying the oil from above as it circulates in relatively small quantities from the bottom of the chamber. The hydrogen introduced under pressure agitates the mixture of oil and catalytic agent.—C. A. M.

Process of making lard substitute [hydrogenised oil]. U.S Pat. 1,114,963. *See* XIXa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Dyes and other products from the waste liquor of the soda cellulose process. Cram. *See* V.

Patents.

Luminous composition. C. P. Karr, Assignor to J. M. Flannery, Pittsburgh, Pa. U.S. Pat. 1,097,979, May 26, 1914; date of appl., Aug. 15, 1912.

A mixture of barium carbonate and sulphate, zinc oxide and sulphide, silica and "asbestine" all in the colloidal condition, is exposed to the emanation from radio-active substances. The material is then dried and made into a paint with any suitable oil other than linseed oil.—W. H. C.

Rosin; Treating ——. F. E. Mariner, Assignor to The Pensacola Tar and Turpentine Co., Gull Point, Fla. U.S. Pat. 1,114,278, Oct. 20, 1914; date of appl., Dec. 23, 1913.

To obtain a lubricating product containing over 65% abietic acid, rosin from which the oil of turpentine has been separated is distilled at a temperature (*e.g.*, 275° C.) below its b. pt. at atmospheric pressure (*e.g.*, by superheated steam), the temperature being finally raised to complete the distillation.—C. A. M.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber factory; Essay on an ideal ——. A. Douglas. India Rubber J., 1914, **48**, 18—19.

The greatest possible cleanliness must be aimed at, and certain precautions in factory-design and equipment are enumerated. There must be no bright light, which darkens the rubber, and no dark corners to harbour fungi. Rainwater should be collected and used for dilution of latex and acid. Smoke chambers should be of wood with heavy corrugated iron roofs lined with sacking. The procedure recommended for the production of smoked sheets is as follows:—The latex is diluted to standard gravity and mixed in a white-tiled tank. From 0·7 to 1% of its bulk of 10% acetic acid is added, and the mixture stirred with a glass rod, and then transferred in pails to the pans, which when full are skimmed and dividing boards introduced. On the following morning the coagulum is gently pressed until about ¾ in. thick, then reduced to ordinary sheet thickness by 3 or 4 passages through smooth rollers, and finally once through marking rollers. The sheet is drained on racks for 2 hrs., then smoked. Decayed timber and coconut husks form good fuel. The rubber is ready to pack in 10 days. In making thick gristly crepe the rubber is first sheeted very thin between smooth rollers, then dried, and finally re-rolled thick in the diamond rollers and dried further. It is ready for packing in 21 days.—E. W. L.

Rubber ; Prohibition of exportations of raw ——.

By an Order in Council, dated November 20th, 1914, the exportation of raw rubber to all destinations is prohibited.

Patent.

Rubber latex ; Means for bringing about the coagulation of ——. C. de C. Pinto, Para, Brazil. Eng. Pat. 16,840, July 15, 1914.

The coagulant consists of creosote, 2 kilos., quinine hydrochloride, 1 kilo., and sodium carbonate, 1 grm., dissolved in a sufficient quantity of alcohol. Ten grms. of this liquid are mixed with 200 grms. of whey from rubber milk and then added to 2 kilos. of the latex.—W. P. S.

XV.—LEATHER ; BONE ; HORN ; GLUE.

Leaching experiments [with tanning materials] ; Laboratory apparatus for ——. L. Balderston and W. K. Alsop. J. Amer. Leather Chemists' Assoc., 1914, 9, 484—489.

The authors have devised small leaches with which it is possible to obtain in the laboratory more information as to how materials will work in practice than can be obtained from the ordinary analysis. The leaches are of tin-coated copper, and the brass lids, with rubber gaskets, are bolted on. In the lid are three perforations, one for the entrance of liquor, another for a thermometer, and one for an air-vent. The leaches are provided with false bottoms of fine copper gauze, and the liquor escapes from beneath by a brass tube which is connected with the next leach by a ground "lip union." A series of leaches is arranged on steps, so that the tail leach is highest. Such a series has worked well for eight months.—F. C. T.

Hide powder ; Adoption of standard ——. Leather World, 1914, 6, 766—777.

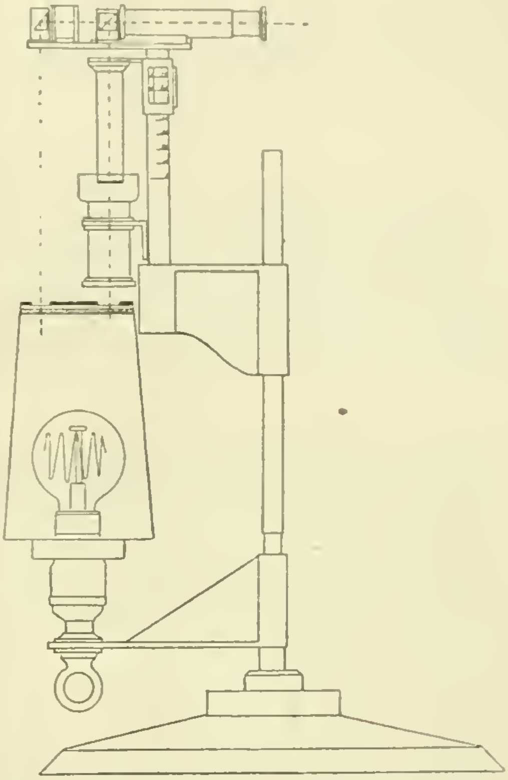
Owing to discrepancies in analytical results of tanning materials arising out of the use of different hide powders the British section of the International Association of Leather Trades Chemists, on the recommendation of a special research committee, have adopted a standard hide powder which must be used in all official analyses. This hide powder is of American origin and can only be obtained from Baird and Tatlock, Ltd., 14, Cross Street, Hatton Garden, London, E.C. New supplies of hide powder will be tested by the Hide Powder Committee and a selected powder will replace the present official powder after Jan. 1, 1915.—T. C.

Tannin extracts ; Determination of insolubles in the analysis of ——. W. K. Alsop. J. Amer. Leather Chemists' Assoc., 1914, 9, 465—466.

Total solids determined with solutions ten times the ordinary analytical strength, have been found to agree within a few tenths per cent. with the amount found by the official method (American). The strong solutions filter sometimes more quickly and sometimes more slowly than those of official strength, and show often a much higher percentage of insoluble matter.—F. C. T.

Tanning materials ; Colour valuation of ——. G. A. Kerr. J. Amer. Leather Chemists' Assoc., 1914, 9, 451—463.

The author describes an improved method of making colour tests on pelt, which complies with two principles that he lays down, first, that the pelt must detannise the solution, and second, that the pelt must be in the same state as hide before tannage. The grain split from limed green salted hides or calf skins is used, and must be prepared as carefully as is hide powder. The author considers the results of no great value to the tanner or extract manufacturer. An improved method of colour measurement of tannin solutions is described. A modified form of the Schmidt and Haensch colorimeter (see fig.) is used. There is no comparison with arbitrarily numbered glasses, but a solution of the same tint as that to be measured is made by mixing standard colour solutions. A cubic centimetre cell of the solution to be tested is placed where the glasses usually are, and the cylinder is used for the mixture of solutions of standard colours. The method is accurate and can be worked rapidly, also the depth of colour solution is in direct proportion to the strength of the solution tested.—F. C. T.



Sulphite-cellulose blends. W. H. Dickerson. J. Amer. Leather Chemists' Assoc., 1914, 9, 489—496.

Results of analyses of mixtures of sulphite-cellulose and various tanning extracts are given. A slight loss of tannin is shown, which was lessened by the use of small quantities (0·1—0·5%) of acetic acid. Tests are recorded of liquors to which sulphite cellulose has been added. Here no loss of tannin resulted, but a decided gain.—F.C.T.

Green salted weight and white weight ; Relation between —— *of various portions of the hide.* F. A. Loveland. J. Amer. Leather Chemists' Assoc., 1914, 9, 463—465.

Hides were rounded, and the various parts taken through the beam-house together, each portion receiving almost exactly the same treatment. The bends were intended to be 50% of the total weight, the bellies 25%, the shoulders 15%, and the heads 10%. The various portions were weighed after going through the beam-house.

	Number of pieces.	Invoice weight of hide.	Per cent. of total hide.	Pelt weight of hide.	Pelt weight per cent. of invoice weight.
Whole hide	3,638	108,237	100·00	125,391	115·8
Bends ..	7,276	52,625	48·62	60,096	114·4

Sole leather ; Bleaching of ——. F. O. Sprague. Shoe and Leather Reporter, Oct. 15, 1914. J. Amer. Leather Chemists' Assoc., 1914, **9**, 496—497.

Five vats are used in the order: water, alkali, water, acid, water, or water, alkali, acid, acid, water. The temperatures, except for the last vat, are from 125° to 130° F. (52°—54° C.). Sulphuric acid is used, and the alkali is sodium carbonate. The loss in solids removed from the leather is very slight, varying from 1·5% to 4%.
—F. C. T.

Analyses [of leather, tan liquors, etc.] ; Standard forms for reporting ——. W. K. Alsop. J. Amer. Leather Chemists' Assoc., 1914, **9**, 479—484.

From information received from members of the Amer. Leather Chemist's Assoc., the author has suggested forms for the uniform report of analyses of leather, tan liquors, barks and extracts. Completeness has been aimed at in the suggestions, for instance in the analysis of liquors, the proportion of tannin to 1° Barkometer, and proportion of tannin to acid are to be given.—F. C. T.

Patents.

Composition of matter [leather preservative] and method of producing the same. S. M. Darling, Chicago, Ill. U.S. Pat. 1,114,590, Oct. 20, 1914 ; date of appl., Sep. 30, 1912.

Oil or tar from the destructive distillation of lignite is distilled to dryness, and the fraction of b.pt. over 350° F. (177° C.) is redistilled while a current of oxygen is blown through it until a wax-like residue is left. This is mixed with an oxidising oil to form a leather preservative.
—C. A. M.

Glue ; Manufacture of [vegetable] ——. Perkins Glue Co., Lansdale, Pa., U.S.A., and H. C. Heide, Liverpool. Eng. Pat. 23,421, Oct. 16, 1913. Addition to Eng. Pat. 24,692, Nov. 6, 1911.

See Addition of Oct. 28, 1913, to Fr. Pat. 436,297 of 1911 ; this J., 1914, 559.—T. F. B.

XVI.—SOILS ; FERTILISERS.

Argillaceous sediments ; Chemistry of the ——. G. Linck. Mitt. K. K. Techn. Versuchsamtes, 1914, **3**, [1], 19—22.

The hydrolysis of silicates and leaching out of alkali and alkaline-earth metals which mark the first stage in the transformation of eruptive minerals into sedimentary deposits lead to the disappearance of Ca, Na, Mg, and K in the order given ; subsequently, as a result of adsorption by the degraded silicates, these metals are taken up again in the inverse order. The excess of alumina over the sum of the alkali and alkaline-earth metals is greater, therefore the more complete the degradation and the more recent the deposit (*i.e.*, the more incomplete the process of adsorption). The molecular ratio of adsorbed alkalis and alkaline-earths to alumina cannot probably exceed 1 : 2 or 1 : 3, but the natural ratio is often disturbed by the admixture of carbonates, etc., during deposition. Analytical data for a number of sedimentary deposits and eruptive rocks are given in the form of a diagram.
—F. Sodn.

Humic substances ; Influence of —— *on the weathering of silicates.* H. Niklas. Diss., Kgl. Techn. Hochschule, München, 1913. Kolloid-Zeits., 1914, **14**, 58.

Finely-powdered felspar, augite, hornblende, olivine, mica, and labradorite respectively were mixed with peat and the mixtures kept for 7 years in closed vessels and then examined. No appreciable quantities of the silicates were brought into solution nor were they rendered less resistant to hydrochloric acid. After incinerating the peat, however, the residual silicates were more easily attacked by hydrochloric acid than the original minerals. By the prolonged action of water on the silicate-peat mixtures, mostly silica and alkalis were dissolved, lime and magnesia only to a slight extent ; and by subjecting the mixtures to electrolysis, mostly iron and aluminium were dissolved.—A. S.

Vanillin in soils ; Origin of ——. *Vanillin in wheat and in the water in which wheat seedlings have grown.* M. X. Sullivan. J. Ind. Eng. Chem., 1914, **6**, 919—921.

Experiments are described showing that vanillin is present in wheat seeds and seedlings and in the water in which wheat seedlings have grown, the quantities found ranging from a trace up to 18 parts per million, referred to the weight of original seeds : the vanillin content increases during the early growth of the plant. A larger quantity of vanillin can be extracted from the seeds if they be first treated with dilute sulphuric acid ; and the vanillin is probably present, at least in part, in the form of coniferin. Vanillin has also been detected in rotten oak wood, in pineapple pulp and parings, and in the hot water extract of lawn grass, consisting of blue grass and a small amount of white clover. (See also this J., 1914, 432.)—A. S.

Manures ; Researches and observations on the movements of —— *in the soil.* J. Lefèvre. L'Engrais, 1913, **28**, 908. Chem.-Techn., Rep., 1914, **38**, 218—219.

In a soil containing 13—16% H_2O, it was found that at the end of a month potassium chloride had diffused 6 cm. horizontally and 10 cm. vertically from the spot where it was applied. Experiments made by Malpeaux, Lefort, Müntz, and Gaudechon in the years 1910 (moist) and 1911 (very dry) show that saltpetre in sandy soils (without vegetation) under the influence of natural rain moves upwards, this being due to the capillarity of the soil and to the evaporation of the surplus moisture. These considerations apply to a greater degree to soils under cultivation, and depending upon the stage of growth of the plants, manuring should be carried out at different times, it being possible then to retain the fertiliser at the desired depth in the soil.—J. P. O.

Nitrogen ; Fixation of —— *by so-called zeolites.* G. Wiegner. J. Landw., 1913, **61**, 11. Kolloid-Zeits., 1914, **14**, 55—56.

When a solution of an ammonium salt is placed in contact with a zeolite (permutite), ammonium ions are adsorbed by the solid and are replaced by an equivalent quantity of cations (mostly Ca- and Na-ions) from the latter. Equilibrium is rapidly attained and the percentage of ammonia thus fixed, referred to the total quantity of ammonium salt present, is lower the more concentrated the solution. This adsorbed ammonia is available for plants only after it has been brought into solution, *e.g.*, by carbonic acid secreted by the plants. Assimilation of the dissolved ammonium salt by the plants displaces the equilibrium, which is, however, rapidly restored, and the zeolite thus acts as a regulator preventing the injurious action of high concentrations of the salts.—A. S.

Lime rich in hydrated silica as a fertiliser. H. Immendorff. Landw. Versuchsstat., 1913, 79—80, 891. Kolloid-Zeits., 1914, 14, 57.

Silicious lime is usually considered to be unsuitable as a fertiliser. Mixtures of different kinds of heavy soils with samples of lime containing varying proportions of soluble silica, were incorporated with water and test-pats of the mixtures allowed to harden, control tests being also made with the soils alone. In all cases the soils alone gave harder products than when mixed with lime, even when a highly silicious lime was used. Field tests gave corroborative results, and it was found that addition of cement containing 19·5% soluble silica also produced a loosening of the soil. If the lime applied to soil be uniformly distributed, even large applications will not cause any hardening or incrustation, and a moderate content of hydrated silica is advantageous owing to its adsorptive power.—A. S.

Bone meal; Influence of fineness upon the availability of ——. S. S. Peck. J. Ind. Eng. Chem., 1914, 6, 922—926.

A commercial bone-meal was divided by sifting into the four sizes: less than 40-mesh, 20—40-mesh, 12—20-mesh, and larger than 12-mesh, and with each grade laboratory experiments were made on the rate of formation of ammonia, nitrates, and soluble phosphoric acid respectively in presence of soil. The results confirmed the view that the efficiency of the meal as a fertiliser increases with its degree of fineness. As a standard for commercial bone meal it is suggested that 65% should pass a 50-mesh and at least 90% of the remainder should pass a 25-mesh sieve.—A. S.

Ammonium citrate solution; Exact and easy method for preparing a neutral ——. J. M. McCandless. J. Ind. Eng. Chem., 1914, 6, 921—922.

The purity of the citric acid used is first determined by titration with $N/10$ caustic soda in presence of phenolphthalein and a solution is then prepared containing a quantity equivalent to 1850 grms. of the pure acid ($C_6H_7O_8,H_2O$) in 7 litres. A solution is also prepared containing 25 c.c. of concentrated ammonia per 500 c.c., and its strength is determined by titrating a portion with $N/2$ acid in presence of methyl orange. The citric acid solution is neutralised with the calculated quantity of the ammonia solution (1 part NH_3 to 3·765 parts $C_6H_8O_7$), and the mixture is shaken well, allowed to cool and diluted till it has the sp. gr. 1·09 at 20° C.

By adding a large excess of strong alcohol to an ammoniacal solution of ammonium citrate, a precipitate was produced which became crystalline on standing overnight. The crystals were filtered off and washed with strong alcohol, with the aid of the pump, and dried between paper. When dissolved in water the solution was distinctly alkaline to corallin (the indicator prescribed by the Amer. Assoc. of Official Agricultural Chemists for the preparation of neutral ammonium citrate solution): the ratio of $NH_3 : C_6H_8O_7$ was 1 : 3·768.—A. S.

Volumetric determination of small quantities of potassium. Zaleski. *See* XXIII.

XVII.—SUGARS; STARCHES; GUMS.

Refractometer; Use of the —— *for the analysis of sugar factory products, and the direct determination of the Brix (dry substance) of the juice of the beetroot.* [*Comparison between the original and improved types of refractometer.* H. Pellet. Intern. Sugar J., 1914, 16, 521—523.

Attention is called to experiments recently made by Mezzadroli at the Beet Cultivation Station, Rovigo, Italy, showing that in determining the density of beet juice by means of the refractometer the result obtained by reading in the presence of the pulp is practically the same as that found with the expressed juice freed from the pulp, provided that the intensity of the light generally used be increased by the use of an electric lamp of about 50 c.p. Similarly the author has proved that in taking the refractometric index of a massecuite of the first or second jet the presence of crystals does not disturb the result. It is considered that the "new" or Schönrock type of refractometer adapted for use in sugar laboratories (this J., 1914, 153) is less sensitive than the original instrument, and that the fact that the maximum Brix capable of being read without dilution is only 85° is a further disadvantage. The results given by the two instruments do not agree. Those obtained with the "new" instrument are nearer the "true" dry substance found by desiccation, while those found with the "old" refractometer approach more closely those indicated by the hydrometer reading, as the following average figures for the dry substance of a beet juice show: "true" dry substance (by desiccation), 13·86, "new" type of refractometer, 13·80; "old" type of refractometer, 14·21; and Brix hydrometer, 14·96%.—J. P. O.

The beet sugar industry in Europe. Board of Trade J., Nov. 19, 1914. [T.R.]

The National Sugar-Beet Association, Ltd., has published the following statistics relating to the beet sugar industry in the principal countries of Europe during the last three seasons:—

—	Factories.	Beetroot.			Raw Sugar production.
		Area cultivated.	Total yield.	Yield per acre.

Recovery of spent lime from causticising operations [and in sugar factories]. Payne. *See* VII.

Molhant process of fermentation in the cane molasses distillery. Miroir. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation ; Molhant process of —— in the cane molasses distillery. V. Miroir. Bull. Assoc. Chim. Sucr., 1914, 31, 936—940.

EXPERIMENTS made in a cane molasses distillery in Madeira with the Molhant process (this J., 1913, 956) showed it to possess the following advantages over the method of working generally in vogue : (1) the yield of alcohol is greater ; (2) the daily production is increased in consequence of the larger volume passing through the distillation columns ; (3) the steam consumption is less ; (4) the spent wash has a higher concentration and hence requires less evaporation to render it fit for utilisation ; and (5) it may be worked for nearly a year without the yeast being renewed.—J. P. O.

PATENTS.

Malting grain, and withering, drying and curing malt ; Machine for ——. J. Sleeman. Eng. Pat. 23,488, Oct. 17, 1913. (See also Eng. Pat. 22,204 of 1911 ; this J., 1912, 1091.)

A CLOSED rotary cylinder, with inlets and outlets for air and grain, is provided inside with an immovable perforated floor running from end to end, to support the whole charge during malting and curing, and one or more floors situated above, which can be removed or folded back against the internal walls of the cylinder, and on which part of the charge can rest during the withering and drying processes.—J. H. L.

Vessels for use in breweries, distilleries and the like ; Sterilising ——. G. W. Smallwood, St. Austell, Cornwall. Eng. Pat. 25,239, Nov. 5, 1913.

FERMENTING vats, refrigerators, etc., are coated on their interior with a composition consisting of 75 to 90% of kaolin and 10 to 25% of a solution of either formaldehyde (sp. gr. 1·080), calcium bisulphite (sp. gr. 1·070), or sulphurous acid (sp. gr. 1·030) ; the vessels are ready for use when the coating has dried.—W. P. S.

Brewers' filtering apparatus. O. Selg, New York. U.S. Pat. 1,101,098, June 23, 1914 ; date of appl., Feb. 16, 1914.

THE filtering vessel, provided with lid, manhole and sparging apparatus is made with a number of hopper-shaped sections at the bottom. Each section is composed of two inclined walls converging towards the bottom, leaving between their lower edges an opening which is closed by a horizontal perforated plate on hinges. The lower part of this trough is surrounded by a jacket the bottom of which is closed by a solid hinged plate corresponding to the upper perforated plate. The liquid which filters through the perforated plate is accumulated in the jacket and withdrawn through pipes situated at a high level in the external pocket. These pipes communicate with a main filtrate pipe provided with a vent which can be opened to the atmosphere when suction is not required. In each hopper-section is mounted a peaked presser-plate above the perforated plate which can be adjusted vertically by a rack so as to pack the lower layers of the filter-bed more or less closely against the plate.—J. F. B.

Alcohol ; Apparatus for the elimination of fusel-oils during the distillation and rectification of ——. F. Pampe, Halle-on-Saale, Germany. U.S. Pat. 1,116,322, Nov. 3, 1914. Date of appl., Aug. 8, 1905.

SEE Eng. Pat. 8476 of 1905 ; this J., 1906, 230.—T. F. B.

Process of manufacturing alcohol from garbage. U.S. Pat. 1,114,017. *See* XIXB.

XIXA.—FOODS.

Milk ; Composition of —— as shown by analyses of samples of known purity made by the Massachusetts State Board of Health. H. C. Lythgoe. J. Ind. Eng. Chem., 1914, 6, 899—908.

THE results of the examination, during the past six years, of 600—700 samples of milk of known purity are tabulated ; fairly complete analyses were made of nearly 500 of the samples, of which 434 were from individual cows and the remainder from herds. The composition of the milk varied chiefly according to the breed of the cow and only to a lesser extent with the period of lactation and the season. In the case of the milk from herds, the total solids ranged from 11·56 to 14·57% ; fat, 3·35—5·40% ; protein, 2·66—4·02% ; ash, 0·65—0·79% ; solids-not-fat, 7·63—9·48% ; lactose, 4·35—5·25% ; protein : fat ratio, 0·66—0·95 ; fat in total solids, 28·2—37·1% ; refraction of copper serum at 20° C. ; 36·7°—38·8° ; of acetic serum at 20° C., 41·8°—44·6° ; of sour milk serum at 20° C., 41·3°—43·5° ; ash of sour milk serum, 0·764—0·852 grm. per 100 c.c. The copper serum was prepared by adding 4 vols. of milk to 1 vol. of copper sulphate solution (72·5 grms. per litre, adjusted to give a reading of 36° at 20° C. on the scale of the Zeiss immersion refractometer or to the sp. gr. 1·0443 at 20°/4° C.), shaking well and filtering. The acetic acid serum was prepared by Leach and Lythgoe's method (this J., 1904, 1116) or by Pfyl and Turnau's modification (Arb. Kais. Ges., **40**, 247), 50 c.c. of milk being shaken with 5 c.c. of carbon tetrachloride in a shaking machine for 5 mins., then treated with 1 c.c. of 20% acetic acid, again shaken for 5 mins., centrifuged, and the clear serum poured off. Watering and skimming of milk may be detected within reasonable limits from the content of total solids and fat. The values for lactose are calculated with the aid of the formulæ :

$$\text{I. } S = TS - \left[F + 0{\cdot}7 + \left(TS - \frac{TS}{1{\cdot}34}\right)\right] ;$$

$$\text{II. } S = TS - \left\{F + 0{\cdot}7 + [0{\cdot}4(F - 3)] + 2{\cdot}8\right\},$$ where S=lactose, TS=total solids, F=fat, and 0·7=ash, and from these values a table is constructed for milks of fat content (horizontal columns) between 2·5 and 5·0% and content of total solids (vertical columns) between 10·5 and 13·6%. When the difference between the values calculated by the two formulæ does not exceed 0·1, the milk is regarded as pure and heavy dividing lines are drawn in the table to divide such milks from those in which the difference exceeds 0·1. Samples falling above the upper dividing line may be suspected of being skimmed and those falling below the lower dividing line of being watered. There is no relation between the refraction of the milk serum and the ash content of the sour serum, and if both values are below the minimum for pure milk, it is a positive indication of the presence of added water. If the protein-fat ratio exceed 1, skimming is indicated ; and if this ratio be below 0·7 or the percentage of fat in the solids be above 35, samples may be declared watered if the serum have a low refraction, not necessarily below the minimum value ; in normal milk with a protein-fat ratio below 0·7, the refraction of the copper serum should be above 37 ; of the sour serum, above 40 ; and of the acetic acid serum, above 41. (See also Richmond, this J., 1911, 1082 ; Ramsay, this J., 1913, 998.)—A. S.

Sucrose and lactose in condensed milk ; Determination of —— by means of acid mercuric nitrate. C. Revis and G. A. Payne. Analyst, 1914, 39, 476—479.

THE authors find that acid mercuric nitrate has a distinct inverting action on sucrose, even in the cold, and that it slightly raises the rotation of lactose : the inversion factor is 141·71 and the lactose factor 0·3086. The following method is recommended for the determination of the two sugars :—65·085 grms. of the condensed milk are placed in a 250 c.c. flask, diluted with water to about 220 c.c., and heated in boiling water for 10 minutes or allowed to stand over-night. The mixture is then diluted to the mark, 100 c.c. of the solution are treated with

10 c.c. of acid mercuric nitrate solution (mercuric oxide dissolved in twice its weight of nitric acid, sp. gr. 1·42, and then diluted to 5 times its volume with water) in a stoppered cylinder, shaken violently for about 30 seconds, and after standing for 5 minutes, filtered. The filtrate is polarised at 20° C. Twenty-five c.c. of the filtrate are then placed in a stoppered 50 c.c. flask, weighed, heated in boiling water for 8 minutes, cooled, the weight is adjusted, and the solution is polarised at 20° C. The readings are corrected for the increase in volume due to the added mercuric nitrate, less the volume of the fat and protein; this correction, C, will be :—

$$C = 10 - \left(\frac{(F \times 1{\cdot}11) + (P \times 0{\cdot}82)}{100} \times 26{\cdot}031\right)\text{c.c.,}$$

and the readings must be mutiplied by (C × 100). The following formulæ then give the percentages of sugars :—

$$\text{Sucrose} = \frac{(D-I) \times 100}{R_c - \frac{T}{2}} \quad \text{Lactose} = (D-S) \times \frac{R_L}{26.031} \times 100,$$

where D = direct reading; I = invert reading; R_c and R_L = the inversion and lactose factors, and T = the temperature of the invert reading.—W. P. S.

Grain dusts; Explosibility of ——. H. H. Brown. J. Ind. Eng. Chem., 1914, **6**, 934—937.

In laboratory experiments in the U.S. Bureau of Mines different grain dusts were tested by Wheeler's method (this J., 1913, 447) in the condition as received from the mill, without drying, and the ignition temperatures found varied from 995° C. oat and corn (maize) elevator dusts, 1015° C. for feed dust from dust collector, 1020° C. for ground oat hulls, 1025° C. for yellow-corn dust, to 1115° C. for wheat elevator dust and 1235°—1270° C. for flour dusts. Wheeler's method gives the relative ignition temperatures but not the relative inflammability, and to determine this an explosion flask of about 1400 c.c. capacity was used in which a dust cloud was driven against a platinum coil heated to a known temperature (measured by a thermo-couple), and the pressure developed measured by a Crosby pressure gauge. Experiments were made at 1200° C., 1100° C., 1000° C., and 900° C. respectively, and the results obtained are given in diagrams. Most of the grain dusts were more inflammable than the Pittsburgh coal dust used as a standard in the U.S. Bureau of Mines, higher pressures being developed, especially at the lower temperatures. Dusts from oats and yellow corn appeared to be more inflammable than those from wheat or other grain. The pressure developed was considerably increased when the dusts were previously dried. A large number of the recent explosions in grain mills appear to have been caused by the introduction of foreign material into grinding machines. The causes which have been assigned to many of these explosions and the various preventive measures which have been suggested are mentioned. (See also this J., 1912, 599, 699; 1913, 764, 808, 1080.)—A. S.

Chlorine-bleached flour; Some characteristics of ——. C. A. A. Utt. J. Ind. Eng. Chem., 1914, **6**, 908—909.

Unbleached flour may contain up to 576 parts Cl per million; flour bleached with chlorine contains over 600 parts per million. The chlorine in bleached flour can be detected by the copper wire flame reaction applied to the oil extracted from the flour by benzene (Alway, Bull. 102, Nebraska Expt. Stat., 53); unbleached flour which has been in contact with bleached flour may also give the reaction. The treatment with chlorine increases the acidity of the flour and does not improve its bread-making qualities.—A. S.

Phosphoric acid; The rapid determination of —— in dough, etc. L. Sobel. Schweiz. Woch. Chem. Pharm. 1913, **51**, 677. Chem.-Techn. Rep., 1914, **38**, 116.

25 grms. of dried and powdered dough are ground three times with 96% alcohol (100 c.c. each time), the extracts being filtered and the residue washed with alcohol till 300 c.c. of solution are obtained. An aliquot part of the solution is evaporated with 2 to 3 grms. of magnesium chloride and 3 grms. of potassium nitrate and incinerated. The ash is dissolved in dilute hydrochloric acid and the phosphoric acid estimated as ammonium magnesium phosphate.—J. B.

Prussian blue in tea; Determination of ——. C. W. Knight. J. Ind. Eng. Chem., 1914, **6**, 909—910.

One hundred grms. of the finely powdered tea are thoroughly moistened with 85% phosphoric acid (30—40 c.c.) and the mixture distilled, the vapours being passed into a mixture of 4 c.c. of 10% caustic soda solution and 30—40 c.c. of water contained in a flask placed in cold water. When the distillation is finished, the contents of the receiver are filtered, neutralised, if necessary, with 10% caustic soda solution and 3 c.c. excess of the alkali, a small crystal of ferrous sulphate, and a few drops of 10% ferric chloride solution added. The mixture is boiled for 1 minute, made distinctly acid with hydrochloric acid of sp. gr. 1·2, filtered, and the precipitate washed with 95% alcohol. It is then treated successively with about 4 c.c. of 10% caustic soda solution and 8 c.c. of water, the solution acidified with acetic acid, treated with a few drops of hydrochloric acid and of ferric chloride solution and then with hydrochloric acid until no brown coloration remains. The solution is evaporated to half its bulk, diluted somewhat, and the Prussian blue collected in a Gooch crucible, washed with very dilute hydrochloric acid, water, alcohol, and ether, dried at 100° C. and weighed. One part of Prussian blue in 200,000 and, in some cases, in 300,000 can be detected by the method, and in two independent determinations on the same sample, 0·0019 and 0·0016% respectively were found. —A. S.

Diastase of alfalfa; An investigation of the —— and the effect of rapid curing on the food value of alfalfa. R. C. Shuey. J. Ind. Eng. Chem., 1914, **6**, 910—919.

The diastatic activity of alfalfa is greater in the morning or after a period of darkness than after a period of exposure to light; much greater during summer than during the spring or autumn; and greater in young plants than in older ones. For example, in the case of the plant dried at 50° C. the activity (grms. of maltose produced from soluble starch by 1 grm. of sample in 1 hour at 40° C.) was 0·92 in the evening and 1·25 in the morning; for plants cut in the morning, the activity was 0·75 in May, 0·84 in July, 1·51 in August, and 1·25 in October; and in the case of plants 12 ins. and 6 ins. high, cut in November, the activities were 1·03 and 1·24 respectively. The activity is diminished by drying at elevated temperatures (even 50° C.) in a humid atmosphere, but markedly increased by drying in a current of air with gradually increasing temperature. The conditions which favour the production of hay of good colour and odour are also favourable to high diastatic activity. Light and weathering in the field tend to destroy the diastase and rain during curing is very detrimental. Alfalfa of high diastatic activity generally shows a greater solubility by auto-digestion than samples low in diastase, but the degree of solubility cannot be increased beyond a certain limit. The loss of digestible constituents during the handling and curing of alfalfa in the field may range from 20 to 30%. Hay of better colour, odour and flavour can be produced by curing by artificial heat on the counter-current principle than by other means, and the hay appears to retain many of the valuable properties of the green plant ordinarily lost in curing. With a dryer located near both the field and the source of fuel, the cost of artificial drying would be less than the losses generally sustained in field curing.—A. S.

Patents.

[*Margarine manufacture.*] *Production of emulsions.* S. H. Blichfeldt, Southall, Middlesex. Eng. Pat. 23,653, Oct. 18, 1913. (See also Eng. Pat. 7498 of 1912; this J., 1913, 763.)

One ingredient is passed through a continuous narrow channel the walls of which move relatively to one another, and the second ingredient is introduced at successive points in the channel. In the apparatus described a disc rotates within a fixed casing, with only a narrow, adjustable, space (10—100μ) between the sides of the disc and the walls of the casing. One ingredient is introduced into this space at the centre of the disc, and travels to the circumference. The second (fatty) ingredient is injected through passages in the walls of the casing, at successive distances from the centre. To ensure an equal pressure on the liquid at both sides of the disc, the latter is perforated by concentric slots, and rides loosely on the driving shaft. The second ingredient is supplied from a revolving tube, geared from the main shaft and provided with outlets which register intermittently (and at different times for different distances from the centre of the disc) with the passages in the walls of the casing. The slots in the disc are so disposed as to face the passages through which liquid is at any given time being injected, so that the liquid passes freely to both sides of the disc.—J. H. L.

Liquids [milk, cream, butter fat, etc.]; Device and process for treating ——. A. O. Fox and R. R. Bates, Assignors to General Purification Co., Madison, Wis. U.S. Pats. (A) 1,114,874 and (B) 1,114,875, Oct. 27, 1914; date of appl., July 9, 1913.

(A) The apparatus comprises a receptacle for the liquid, means for forcing gas under pressure (upwards) into the receptacle, and a stationary device below the surface of the liquid provided with inclined faces separated at their edges so that the rising gas is divided and deflected. The receptacle may be provided near the top with a device for obstructing passage of the liquid out of the apparatus. (B) Air admixed with hypochlorous acid, *e.g.*, by passage through aqueous solutions of unstable hypochlorites, is forced under pressure through milk, cream, butter fat, etc.—J. H. L.

Food for animals and process for the manufacture of the same. The Molassine Co., Ltd., East Greenwich, and J. J. A. de Whalley, Lee, Kent. Eng. Pat. 24,912, Nov. 1, 1913.

Amylaceous material, such as middlings or maize residue, is treated with 2% of its weight of sulphur dioxide in the form of an aqueous solution, and heated for 15 minutes under a pressure of 4 atmospheres. The steam and acid are then blown off, any remaining acid is neutralised by the addition of calcium carbonate or sodium carbonate, and the product is dried and ground.—W. P. S.

Lard substitute [hydrogenised oil]; Process of making ——. J. C. Chisholm, Assignor to The Chisholm Process Oil Refining Co., Dallas, Tex. U.S. Pat. 1,114,963, Oct. 27, 1914; date of appl., Oct. 8, 1912. (See also this J., 1914, 1062.)

The oil is caused to pass by centrifugal action through curved passages formed by spirally-wound coils of wire, the surface of the wire forming a catalytic agent; the operation is carried out in an atmosphere of hydrogen. —W. P. S.

Canned foods; Process for preventing the spoilage of ——. E. W. Duckwall, Aspinwall, Pa. U.S. Pat. 1,114,972, Oct. 27, 1914; date of appl., March 29, 1913.

Sample tins of a stock of canned foods are incubated for a suitable length of time, then opened, and a portion of the substance from the centre of the tin is examined bacterioscopically. Should the presence of bacteria be detected, the remainder of the tins are heated in boiling water for a period of time sufficient to heat the contents throughout to not less than 180° F. (82° C.).—W. P. S.

XIXb.—WATER PURIFICATION; SANITATION.

Filtration of drinking water: Biological results of the rapid ——. R. Kolkwitz. J. Gasbeleucht., 1914, **57**, 724—726.

Experiments in connection with an investigation of the Barmen valley water led to the adoption of a new method of clarification. A water can be made clear and rendered free from suspended matter by passing through a silk net or a very fine copper sieve with 10,000 meshes per sq. cm. An uninfected water may be considered as clarified by rapid filtration when it contains not more than 1 c.c. of suspended matter per cub. m., the suspended matter being matter larger than $\frac{1}{15}$ mm. In a laboratory test, 50 litres of the water are filtered and should not yield more than 0·05 c.c. of suspended matter. Under the low powers of the microscope the filtered water can be seen to contain *Asterionella*, *Synedra*, *Gymnodinium*, etc. A clarity test for the filtered water can be carried out in a tube 10 m. long with its ends closed by glass plates; when this tube is filled with the water, a candle flame held at one end should be visible through the water from the other end.—J. H. J.

Hard water; Taste of ——. A. Friedmann. Z. Hyg. u. Inf. Krankh., **77**, 125—142. J. Gasbeleucht., 1914, **57**, 452.

Carbon dioxide was dissolved in pure distilled water at 15°—17° C. With up to 116 mgrms. per litre no effect was produced, but with from 116 to 246 mgrms., the opinions of different persons varied as to the taste. In hard water, carbon dioxide could be tasted in much smaller concentration than in distilled water; 52·5 mgrms. per litre were detected in water of 36·4° hardness (German) at 14·2° C. A water with 173 mgrms. per litre of free CO_2 was returned as distinctly acid. The taste of distilled water containing free CO_2 became suspicious at 126 mgrms. per litre and this uncertainty continued up to about 260 mgrms. The earlier suspicions of taste were described by the term "refreshing."—J. H. J.

Lead poisoning caused by a water-supply. M. Neisser. Gesundheits-Ingenieur, 1913, 920; J. Gasbeleucht., 1914, **57**, 139.

Numerous cases of more or less severe lead poisoning occurring in a village were found to be caused by the water supply containing lead. The mains and service pipes were made of lead and the water was found to contain from 7·7 to 12·5 mgrms. Pb per litre; the pipes themselves were coated inside with a thin white film consisting of 96% of lead carbonate. The lead could be removed from the water by filtration through a Berkefeld filter. The water having this action on the lead pipes contained:—Cl 1·5, N_2O_5 12·0, dissolved O_2 10·1, free CO_2 18·6 mgrms. per litre. The carbonate-hardness of the water was 0·64° (German), and neither nitrite nor ammonia were present.—W. P. S.

Sewages; Biochemical oxygen demand of ——. A. Lederer. J. Ind. Eng. Chem., 1914, **6**, 882—888.

An account is given of co-operative work by members of a sub-committee of the Laboratory Section of the American Public Health Association appointed to consider the standardisation of a test for determining the oxygen-consuming capacity of a sewage. Experiments were made with various modifications of the incubation method recommended by the English Royal Commission on Sewage Disposal (compare this J., 1912, 1197; 1913, 265). No completely satisfactory results were obtained, but the following "Modified English Incubation Test" is to be recommended for adoption as a provisional method at the next annual meeting of the American Public Health Association. A definite volume of sewage or effluent is mixed with aerated distilled water or tap water, free from nitrates and nitrites, in such proportion that between 30 and 60% of the available oxygen is consumed when the mixture is incubated for 10 days at 20° C. The water for diluting should be stored for 1 or 2 days at 20° C. before use. For the incubation a bottle of 250 c.c. capacity, with a seal such as is often used for the Methylene Blue putrescibility test, is employed. If it be desired to use a shorter period of incubation, then the percentage ratio of absorption for 1, 5 and 10 days, at the proper concentration, at various times, must first be determined for the particular dry weather flow sewage, in order to ascertain the factors for calculating results obtained by incubation for 24 hours into those obtainable after 5 or 10 days. The results should be expressed in mgrms. of oxygen absorbed per litre of crude sewage or effluent, and they should be given for periods of 24 hours and 10 days respectively to facilitate comparison of different sewages.—A. S.

Methane; Physiological effect of ——. O. Rybak. Braunkohle, 1914 [5], 72—73. J. Gasbel., 1914, **57**, 624—625.

THE bodies of persons killed in firedamp explosions do not show signs of suffocation. Experiments made with gas from a mine, containing CH_4, 92·5; CO_2, 1·0; O_2, 1·6; and N_2, 4·9%, showed that methane produces a slight narcotic effect, not however sufficient to show marked symptoms unless other predisposing conditions are present, such as lack of oxygen or excess of carbonic acid in the blood.—A. T. L.

Lead and zinc smelters; Working and health conditions of —— in Germany. Metall und Erz, 1914, **11**, 1—9.

FROM 1879—1885 out of 1200 men engaged directly in zinc smelting there were 427 cases of lead colic, with a maximum of 221 in 1881. During 1896—1901 in five large works employing on an average 3780 workers there were 83 cases giving a yearly average of 2·2%. Since 1900 official statistics have been collected of the age and illnesses of smelters. Statistics for the district of Oppeln show that from 1901—1912 the working age has steadily increased, and the cases of lead colic and lead palsy combined are now approximately 1·2% of the workmen engaged. Disease is reduced by providing larger rooms, good lighting and ventilation, abstraction of poisonous gases; by working short hours, and by sobriety. The illnesses which are particularly noted are lead colic and palsy, nephritis, stomach and intestinal catarrh, blood poorness, rheumatism, and affections of the respiratory organs and of the eyes.—W. F. B.

Larkspur seed; Insecticidal value of fluid extract of ——. J. B. Williams. Amer. J. Pharm., 1914, **86**, 414—416.

THE insecticidal properties of larkspur seeds (*Delphinium ajacis* L.) are due to the oil contained therein, and only to a slight extent to the alkaloid. Extracts prepared with solvents which remove the oil, such as alcohol or light petroleum, give the best results.—F. SHDN.

Explosibility of grain dusts. Brown. *See* XIXA.

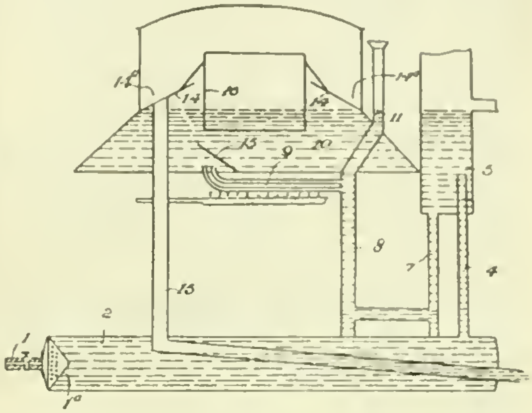
PATENTS.

Water softening plant; Carbonating apparatus for ——. G. W. Bemrose, Bolsover, Derbyshire. Eng. Pat. 12,413, May 20, 1914.

AN apparatus for carbonating the softened water in the Archbutt-Deeley process. In the discharge pipe from the upper softening tank to the lower storage tank is placed a perforated disc for breaking up the flow of water into fine streams. A pipe conveying combustion gases from a coke stove enters the discharge pipe above the perforated disc and is bent downwards to pass through the centre of the disc. The mouth of this pipe is closed and around it are two perforated rings of different diameters, one above the other, communicating with the interior of the pipe. The fine streams of water falling from the perforated disc draw the combustion gases through perforated rings. The water collects in a bucket which closes the end of the discharge pipe, and there solution of the gases takes place. The bucket is situated inside the storage tank and the water overflows from it into the tank.—J. H. J.

[*Water.*] *Distilling apparatus.* R. Bassett and J. H. Staples, Wincanton, Somerset. Eng. Pat. 14,807, June 19, 1914.

WATER enters through the pipe, 1, and the rose, 1*a*, into the cooler, 2, and rises up the pipe, 4, to the constant level chamber, 5. It then passes by the pipes, 7, 8, to the preheater, 9, any gas given off escaping through the pipe, 11. The baffles, 13, 14, 16, prevent the water splashing when it enters the still proper, 10. The vapour given off is partly condensed by contact with the cover and collects in the gutter, 14*a*, and along with any uncondensed vapour passes down the pipe, 15, to the cooler.—W. H. C.



Filtered water from rivers; Apparatus for obtaining ——. M. H. Adams, Whitefield, Lancs. Eng. Pat. 24,284, Apr. 25, 1914.

IN an improved screening apparatus, a basin is made in the river and a rotating disc or wheel placed in the semi-circular entrance to the basin so as to be one-third immersed. Sheets of wire gauze are fitted between the spokes of the wheel. As the wheel rotates the portion of the gauze above the water is cleaned by a water-jet or other suitable method, the material which is removed falling into a trough. A suction pipe conveys the filtered water from the basin.—J. H. J.

Sewage; Treatment of ——. J. O. Böving and Wetcarbonising, Ltd., London. Eng. Pat. 25,056, Nov. 3, 1913.

AN improvement on Eng. Pat. 3247 of 1911 (this J., 1912, 601); the heated sewage or sludge, before being pressed, is passed through a cooling coil to cool it to 30° C., and then into tanks where it is allowed to settle for 4—6 hrs., after which the supernatant liquid is run off. The sludge thus obtained can be pressed more completely and quickly than directly after heating.—J. H. J.

Liquids [sewage, etc.]; Purification of ——. M. Janvier et Cie., Paris. Eng. Pat. 27,775, Dec. 2, 1913. Under Int. Conv., Feb. 3, 1913. Addition to Eng. Pat. 29,192 of 1912 (this J., 1913, 922).

IN apparatus of the kind described in the main specification (*loc. cit.*) the bacterial filter consists of a number of superposed tanks or boxes arranged in a chamber and filled with filtering material; the bottom of each tank is perforated and is turned upwards so as to form one side of the tank, leaving a space between the latter and the inner wall of the chamber. The spaces are arranged alternately on opposite sides so that a current of air may pass upwards and from side to side of the chamber and over the surface of the material in the tanks. A tilting bucket delivers the liquid over a corrugated and perforated plate situated above the uppermost tank.—W. P. S.

Clarifying apparatus for liquids. W. Reid, Hamilton, Lanarkshire. Eng. Pat. 29,184, Dec. 18, 1913.

The clarifying tank is divided into a series of compartments of inverted triangular section, with baffle-boards suspended along the centre of each triangle. The liquid to be clarified enters from a channel along one side of the tank, flows down the sloping side of the first triangle, under the baffle-board, and up the other sloping side into the next compartment. The suspended solids are removed on the sloping sides of the triangles and settle in the apices. Along each apex is a worm conveyor for removing the solids to the end of each compartment and up an inclined plane, and so out of the tank.—J. H. J.

Sewage and analogous liquids; Apparatus for the purification [aeration] of ——. W. Jones and Jones and Attwood, Ltd., Amblecote, Worcestershire. Eng. Pat. 19,915 of 1914; date of appl., Oct. 11, 1913.

A pipe, reaching nearly to the bottom of a tank containing the sewage, extends over a partition to the bottom of a second tank; compressed air is delivered into the end of the pipe in the first tank, thus causing a mixture of liquid and air to pass over into the second tank; the lower end of the pipe in this tank ends in a perforated chamber which distributes the air into the liquid. A supplementary volume of air is introduced into the descending pipe in the second tank.—W. P. S.

Refuse destructor and like furnaces. A. B. Scorer and Meldrums, Ltd., Manchester. Eng. Pat. 28,336, Dec. 9, 1913.

In a furnace having a doorway the full width of the grate, the clinker is withdrawn by means of a rake mounted in front of the doorway; the furnace is also fitted with a movable back plate so that the head of the rake may be placed behind the clinker.—W. P. S.

Alcohol from garbage; Process of manufacturing ——. J. J. Morgan, Chicago, Ill. U.S. Pat. 1,114,017, Oct. 20, 1914; date of appl., Sept. 20, 1909.

The garbage is heated with a dilute acid until the carbohydrates are hydrolysed to dextrose; the acid is neutralised, the dextrose fermented, and the alcohol distilled.—C. A. M.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Belladonna seed; Germination of ——. A. F. Sievers. Amer. J. Pharm., 1914, 86, 483—505.

The germination of belladonna seeds is accelerated by exposure to a freezing temperature indicating the advisability of autumn instead of spring sowing. There appears to be no relationship between the size of the seed and its germinating power. Seeds which sink in water are far better than those which float, only a very small percentage of the latter germinating. When drying the berries should be thinly scattered in a well-ventilated room to avoid mould as far as possible. The vitality of the brown and gray seeds is the same. There is no great advantage in immersing the seeds in concentrated sulphuric acid for 1—10 minutes. Soaking in a 60% solution of commercial hydrogen peroxide for 18—24 hrs. was found to be very effective in increasing the germinating power. Shaking the seeds with powdered glass or rubbing with emery paper has a good effect, which is not nearly so great, however, as that produced by treatment with hydrogen peroxide.—F. Shdn.

Rhamnus Purshiana [Cascara sagrada]; its history, growth, methods of collection and bibliography. C. W. Johnson and E. Hindman. Amer. J. Pharm., 1914, **86**, 387—413.

Rhamnus Purshiana (bearberry, barberry, *Cascara sagrada*) was discovered on one of the tributaries of the Columbia River in Montana in 1805 or 1806. It is found in commercial quantities on the west slope of the Cascade Mts. of Southern British Columbia, Washington, Oregon, and Northern California, at altitudes varying from sea-level to 1800—2000 feet. It grows best on a light sandy soil where there is plenty of moisture, reaching a height of 20—30 ft. and a diameter of 6—8 ins. in about 10 years. Trees of over 4 ins. diameter are felled and the bark peeled during the months of April to September, curing being effected by a few days' exposure to sunshine. The annual production during the decade ending with 1912 averaged about 600 tons. It was first used as a medicine in 1872. —F. Shdn.

Oils of the Coniferae. III. Leaf and twig and cone oils of Western yellow pine (Pinus ponderosa, Laws.) and sugar pine (P. lambertiana, Dougl.). A. W. Schorger. J. Ind. Eng. Chem., 1914, **6**, 893—895. (See also this J., 1914, 1072.)

The results obtained are summarised in the following table:—

	Western yellow pine.			Sugar pine.	
	Leaf oil (10 samples).	Leaf and twig oil (4 samples).	Cone oil.	Leaf and twig oil (7 samples).	Cone oil.
Yield, %	0·040—0·115	0·084—0·126	0·063	0·045—0·120	0·318

Emodin-bearing drugs in presence of phenolphthalein; Detection of ——. L. E. Warren. Amer. J. Pharm., 1914, 86, 444—449.

Phenolphthalein in medicines interferes with the test for emodin-bearing drugs (reddish coloration when the washed benzene extract is treated with dilute ammonia). It can be removed by extracting the evaporated material with ether or acetone, removing the solvent, dissolving the residue in dilute caustic soda and adding iodine solution, followed by hydrochloric acid, which precipitates tetraiodophenolphthalein. After cooling for an hour below 15° C. the tetraiodophenolphthalein is filtered off, excess of iodine in the filtrate removed by sodium sulphite, the solution extracted with chloroform and the chloroform extract treated with caustic soda. The fluid extracts of cascara, rhubarb and senna, but not aloes, give characteristic colorations. Chrysophanic acid may be detected in presence of phenolphthalein by Bailey's method (this J., 1914, 500).—T. C.

Eucalyptus oils ; Determination of the cineol content of ——. H. G. A. Harding. Analyst, 1914, 39, 475—476.

The resorcinol method (see this J., 1908, 90) is unreliable when applied directly to eucalyptus oil ; more satisfactory results are obtained when the portion of the oil distilling between 170° and 190° C. is used, but even then the results are too high when the cineol content exceeds 50%. In such cases the cineol content should be reduced to about 40% by the addition of the fraction of oil of turpentine distilling between 156° and 160° C. ; the use of ordinary oil of turpentine tends to introduce serious errors. The following procedure is recommended :—100 c.c. of the oil are distilled, the portion distilling between 170° and 190° C. being collected separately and diluted to 100 c.c. with the fraction of oil of turpentine, b. pt. 156° to 160° C. A preliminary determination of the cineol in this solution will show whether further dilution is required. Having noted the temperature, from 6 to 10 c.c. of the solution are shaken with warm 55% resorcinol solution in a 100 c.c. flask having a graduated neck : after 5 minutes' shaking, more resorcinol solution is added so as to bring the oil into the graduated neck, the mixture is cooled, and the volume is read.—W. P. S.

Camphor and certain essential oils ; Rapid method for the determination of —— *when in solution in alcohol.* W. B. D. Penniman and W. W. Randall. J. Ind. Eng. Chem., 1914, **6**, 926—928.

For solutions containing 7—15% of camphor or essential oil, 5 c.c. are placed in a Babcock milk bottle, which is then filled nearly to the neck with calcium chloride solution of sp. gr. 1·37. After shaking, 1 c.c. of gasoline (b. pt. 40°—60° C.) is added, the mixture shaken, and made up with calcium chloride solution to near the top of the graduated part of the neck of the bottle. The bottle is then stoppered, shaken violently and whirled in a centrifuge at high speed for 5 mins. If the aqueous solution is still cloudy, the bottle is again shaken and whirled. The volume of the gasoline solution, read off between the lowest point of the lower and the extreme edge of the upper meniscus, is equal to the sum of the volumes of the gasoline and the dissolved camphor or oil. For solutions containing less than 7% of camphor or oil, 10 c.c. are used and a quantity of gasoline not more than twice the volume of the camphor or oil present. Satisfactory results have been obtained by this method with spirit of camphor, and alcoholic extracts prepared from peppermint, lemon, sweet orange, anise and nutmeg oils.—A. S.

Extractions by means of immiscible solvents ; Study of the methods for —— *from the point of view of the distribution coefficients. II.* J. W. Marden and V. Elliott. J. Ind. Eng. Chem., 1914, **6**, 928—934.

Further experiments on the lines described previously (this J., 1914, 501) have shown that for extracting aconitine and codeine from aqueous solution chloroform is preferable to ether ; that chloroform is preferable to mixtures of chloroform and ether for extracting strychnine ; and that ether is a satisfactory solvent for extracting cocaine. In the known methods for the extraction of morphine, it is necessary to shake with the solvent many times in succession to obtain accurate results, but by means of the distribution coefficient it is possible to calculate the total quantity present in the aqueous solution from the amount removed in the first extraction. If *d* be the distribution coefficient, *a* the volume of aqueous solution, and *c* the volume of immiscible solvent, the *fraction* $\left(\frac{x_1}{x_0}\right)$ of material left in the aqueous liquid after one extraction is $\frac{da}{e+da}$, and if W be the weight of substance removed in this extraction, the total quantity present is equal to $\frac{W}{1-\frac{x_1}{x_0}}$. This method gave satisfactory results when applied to the determination of morphine, acetanilide, and saccharin by extraction with a mixture of chloroform and amyl alcohol (3 : 1), chloroform, and amyl acetate respectively.

Experiments with lemon oil and alcohol showed that in the preparation of "terpeneless" lemon extract a larger proportion of citral would be extracted by using 50% in place of 45% alcohol.—A. S.

Radium in therapeutics ; Local application of ——. J. Joly. Scient. Proc. Roy. Dublin Soc., 1914, **14**, 290—296.

To secure better "illumination," small quantities of radium or the purified emanation are sealed in glass capillaries and several of these are applied to the diseased region or inserted by means of needles. Thus instead of a tube containing 200 millicuries of emanation, 20 needles each containing 10 millicuries could be used without any lead screens.—F. Shdn.

Calomel in tablets ; Determination of ——. J. W. Marden and O. E. Cushman. Amer. J. Pharm., 1914, **86**, 511—516.

A quantity of the tablets corresponding to 0·2—1·0 grm. of calomel is triturated with 30 c.c. of water, acidified with nitric acid and sodium peroxide added in small portions till gray metallic mercury separates, when about 1 grm more of the peroxide is added. After heating for a few minutes the mercury is filtered off and washed. The filtrate and washings are made strongly acid with nitric acid, excess of *N*/10 silver nitrate added, the whole shaken well, and the excess of silver titrated with potassium thiocyanate solution.—F. Shdn.

Ash content of drugs ; Proposed limitation of —— *for the United States Pharmacopœia IX.* M. I. Wilbert. Amer. J. Pharm., 1914, **86**, 456—460.

The proposed limitations for the percentage of ash in a large number of drugs for the U.S.P. IX. are tabulated, with the corresponding ash limits in the German, Austrian, Swiss, and Dutch Pharmacopœias, together with the variations in the ash reported in recent literature.—T. C.

Patents.

Chlor-methyl-omega-brom-propyl carbinol and process of producing same. A. B. Davis, Assignor to Eli Lilly and Co., Indianapolis. U.S. Pat. 1,114,734, Oct. 27, 1914. Date of appl., July 14, 1913.

A chloromethyl-ω-bromopropylcarbinol of the formula, $ClCH_2.CH(OH).CH_2.CH_2.CH_2Br$, is obtained by condensing bromo-ethyl magnesium bromide, $Br.CH_2.CH_2.MgBr$, with epichlorhydrin. For example, one mol. of magnesium is dissolved in an absolute ethereal solution of ethylene bromide, one mol. of epichlorhydrin is added, and the carbinol is liberated by treatment with a suitable acid. —T. F. B.

Ketone and process of producing same. A. B. Davis, Assignor to Eli Lilly and Co., Indianapolis. U.S. Pat. 1,114,735, Oct. 27, 1914. Date of appl., July 14, 1913.

The carbinol described in U.S. Pat. 1,114,734 (see preceding abstract) is oxidised, *e.g.*, by means of potassium bichromate and sulphuric acid, to produce the ketone, $ClCH_2.CO.CH_2.CH_2.CH_2Br$.—T. F. B.

Acetylsalicylic acid ; Process for preparing halogen-alkyl esters of ——. R. Wolffenstein. Ger. Pat. 276,809, Dec. 20, 1911. Addition to Ger. Pat. 245,533 (this J., 1912, 661).

Polyhalogen-alkyl esters of salicylic acid are treated with acetylating agents; for example, the trichloro-tertiary butyl ester of salicylic acid is heated with acetic anhydride and anhydrous sodium acetate at 160°—180° C., and the product is treated with water and sodium carbonate solution and finally extracted with ether, which dissolves the ester. (See also Ger. Pat. 246,383 and Eng. Pats. 27,562 of 1911 and 5811 of 1913 ; this J., 1912, 661 ; 1913, 1169).—T. F. B.

Acidylsalicylic acids ; Process for preparing halogen-alkyl esters of ——. R. Wolffenstein. Ger. Pat. 276,810, March 22, 1912. Addition to Ger. Pat. 245,533.

Polyhalogen-alkyl esters of salicylic acid are treated with acidylating agents other than those which introduce the acetyl group.—T. F. B.

Organic selenium compounds ; Process for preparing ——. J. D. Riedel A.-G. Ger. Pat. 276,976, Nov. 2, 1912.

Organic compounds containing selenium are obtained by treating unsaturated fatty acids with selenium-halogen compounds. For example, a mixture of 28 parts of oleic acid and 5·6 parts of selenium tetrachloride is heated, and when the reaction is finished the product is extracted with ether and the extract distilled ; a thick, reddish-brown oil is obtained.—T. F. B.

Oleum cadinum ; Preparation of light-coloured, nearly odourless, non-irritant products from ——. I. Bugarszky, L. Török, and Dr. Kereszty, Dr. Wolf es tsa Vegyészeti Gyár R. T. Ger. Pat. 277,061, Dec. 12, 1912.

Oleum cadinum is fractionated in a vacuum of about 20 mm., to obtain the fraction (about one-third of the oil) of b. pt. 220°—300° C. ; this fraction contains the whole of the constituents of medicinal value, and is a yellow, highly viscous oil with a pleasant, non-penetrating odour, which does not possess irritant properties (compare Ger. Pat. 236,446 of 1910 ; this J., 1911, 1088).—T. F. B.

Double salts of gold hydrocyanic acids and process of making same. G. Spiess and A. Feldt, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,115,608, Nov. 3, 1914. Date of appl., Jan. 16, 1914.

See Eng. Pat. 1837 of 1914 ; this J., 1914, 767.—T. F. B.

Dicantharidylethylenediamin-mono-aurocyanide and process of making same. G. Spiess and A. Feldt, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,115,609, Nov. 3, 1914. Date of appl., Jan. 16, 1914.

See Ger. Pat. 269,661 of 1912 ; this J., 1914, 375.—T. F. B.

Salts of the aurothiosulphuric acid and process of making same. G. Spiess and A. Feldt, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,115,610, Nov. 3, 1914. Date of appl., Jan. 16, 1914.

See Eng. Pat. 1869 of 1914 ; this J., 1914, 806.—T. F. B.

Metal colloids ; Production of ——. H. Crookes and L. Stroud, London. U.S. Pat. 1,116,247, Nov. 3, 1914. Date of appl., Dec. 8, 1913.

See Eng. Pat. 28,776 of 1912 ; this J., 1914, 86.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Explosives ; Thirty-eighth Annual Report of H.M. Inspectors of —— *for* 1913. [Cd. 7650.]

In 1913 there were 33 factories and 85 magazines under continuing certificate, and 103 factories and 363 magazine under licence ; 222 visits were paid to factories and 419 to magazines. *Packing and conveyance :* There has been no alteration in the regulations, apart from a circular of Oct. 20 concerning "Explosive Corks" (alarm cork cartridges). *Importation :* The number of licences granted was 178, as compared with 159 in 1912 and 160 in 1911. The importations were :—

		1912.	1913.
Nitroglycerin explosives	lb.	605,281	1,576,081
Non-nitroglycerin explosives	,,	57,321	51
Detonators	,,	147,610	149,201
Fireworks	,,	876,020	814,882

Imported and transhipped to other countries :—1913 : 1,107,927 lb. nitroglycerine explosives, and 20,910 lb. detonators.

Chemical Advisers' Report : 345 samples were passed by Messrs. Dupré out of 506 examined ; 86 were rejected for wrong composition, 19 for failure to pass heat test, and 17 for exudation; 8 were examined in connection with supposed outrages. *Accidents :* There were 498 accidents in 1913 (456 in 1912) :—

	Totals.	Deaths.	Injured persons.	Accidents not causing death or injury.
Manufacture	86	13	50	46
Keeping	6	4	7	1
Conveyance	3	1	1	1
Use and miscellaneous	403	48	427	2
	498	86	485	50

The number of deaths is above the average, 55·1, for the last ten years.—O. E. M.

Sixth report of the Explosions in Mines Committee. See IIa.

Explosibility of grain dusts. Brown. *See* XIXa.

Explosives in the United States ; Production of —— *in* 1913. U.S. Bureau of Mines. Oil, Paint, and Drug Rep., Nov. 16, 1914. [T.R.]

The total production of explosives in the United States during 1913, according to the figures received from manufacturers, was 463,514,881 pounds (231,757 short tons), as compared with 489,393,131 pounds (244,696 short tons) for 1912. This production is segregated as follows :—Black powder, 194,146,747 pounds ; "high" explosives other than permissible explosives, 241,682,364 pounds, and permissible explosives, 27,685,770 pounds. These figures represent a decrease of 36,146,622 pounds of black powder, and an increase of 7,212,872 pounds of high explosives and 3,055,500 pounds of permissible explosives. In 1902 11,300 pounds of permissible explosives were used in coal mining, whereas in 1913 the quantity so used was 21,804,285 pounds. The total amount of explosives used for the production of coal in 1913 was 209,352,938 pounds. The use of permissible explosives in coal mining has had gratifying results, and few, if any, serious accidents can be attributed directly to their use.

XXIII.—ANALYTICAL PROCESSES.

Potassium ; Volumetric determination of small quantities of ——. L. Zaleski. Landw. Versuchsstat., 1913, **83**, 221. Chem.- Techn. Rep., 1914, **38**, 357.

The potassium is precipitated as cobalt-potassium nitrite as recommended by de Konincks. The reagent is made by dissolving 25 grms. of cobaltous nitrate in 500 c.c. of water with 12·5 c.c. of nitric acid, mixing the solution with an equal volume of 30% sodium nitrite solution, and filtering.

The reagent is added, drop by drop, to the potassium solution, a considerable excess being used, and the solution allowed to stand for 12—24 hrs. before filtering. The potassium factor is determined by a parallel experiment. The method is not suitable for the analysis of manures containing very small quantities of potassium.—A. T. L.

Mercury; Volumetric determination of ——. J. E. Clennell. Eng. and Mining J., Oct. 31, 1914, 787—789.

A RAPID and accurate method for the determination of mercury is based on the precipitation of mercuric oxide by excess of sodium hydroxide, re-solution of the precipitate in a measured excess of standard potassium cyanide solution, and titration of the excess of the latter with a standard silver nitrate solution. Potassium iodide added to the solution serves as indicator, and the end point is marked by the appearance of a yellowish turbidity due to silver iodide. The following reactions are involved:—

$$HgO+4KCN+H_2O=K_2Hg(CN)_4+2KOH;$$
$$K_2Hg(CN)_4+AgNO_3=Hg(CN)_2+KAg(CN)_2+KNO_3.$$

In the case of samples containing mercurous oxide, the mercury can usually be completely dissolved by a preliminary treatment with saturated bromine water. The excess of bromine must be completely removed by boiling before adding the sodium hydroxide. Other metals which react with cyanide, such as copper, nickel, or zinc, can be readily eliminated by utilising the insolubility of mercury sulphide in moderately concentrated nitric acid. The presence of iron obscures the end point in the titration with silver nitrate; it is removed by transforming into the ferric state by adding nitric acid to the solution and boiling before neutralising with sodium hydroxide. On adding the cyanide, ferric hydroxide is precipitated and removed by filtration. To obtain accurate results a large excess of potassium cyanide must be avoided, but a moderate excess of alkali does not affect the results, and the loss of mercury salt on boiling the solution for 30 seconds is negligible.—J. N. P.

Radium; Quantitative determination of ——. H. Schlundt. Met. and Chem. Eng., 1914, 12, 709—710.

IN the emanation method, which consists in introducing the emanation from the ore into a standardised air-tight electroscope or an ionisation vessel connected with an electrometer, the solution method (fusion with mixed alkali carbonates, followed by solution and boiling) of obtaining the emanation from rocks, etc., that do not dissolve in acids upon heating gives only 70—80% of the value obtained by the fusion method. This consists in fusion with a suitable flux such as mixed carbonates of sodium and potassium, in a closed, electrically heated furnace, the liberated emanation being freed from carbon dioxide and collected. Fusion with mixed carbonates appears better than with potassium bisulphate except with carnotite. Borax as flux gives low values. Emanation is completely separated from uranite by solution in nitric acid and by fusion with ordinary fluxes.—W. F. B.

Chlorides in albuminous liquids; Simple and accurate method for the determination of ——. C. Gazzetti. Arch. di Fisiol., 11, 81—88. Kolloid-Zeits., 1914, 14, 58.

A SMALL measured quantity of the liquid is diluted with water in a 100 c.c. flask, treated with 3 c.c. of a 30% solution of ferric alum, the precipitated iron albuminate dissolved by addition of concentrated nitric acid, drop by drop, and a measured excess of *N*/50 silver nitrate added to the clear liquid: the colloidal matter present prevents the formation of a precipitate of silver chloride. The mixture is diluted to about 97 c.c. with water and then made up to exactly 100 c.c. by addition of concentrated nitric acid. This causes the flocculation of the albumin and the precipitation of silver chloride. The whole is filtered and in 50 c.c. of the filtrate the excess of silver is determined by titration with *N*/50 potassium thiocyanate. —A. S.

Solubility determination at high temperatures; Method of ——. L. Tschugaeff and W. Chlopin. Z. anorg. Chem., 1914, 86, 151—162.

SATURATION is effected at the boiling temperature of the solution, and this is made to vary in a series of determinations by altering the working pressure. The saturation vessel, which is immersed in an oil bath at 5—10° C. above the temperature adopted, is fitted with one tube carrying a thermometer and another passing into a weighing bottle which depends into the solution. The tubes are furnished with rubber connections and screw clips, and these are adjusted to admit air at such a rate that any desired reduction of pressure is maintained by means of a filter-pump; constancy of pressure is preferably secured by a mercury pressure regulator. When saturation is complete (in about an hour), a sample of the solution is drawn through a filter-tube into the weighing bottle for analysis.—F. SODN.

PATENT.

Calorimeter. S. W. Parr, Urbana, Ill. U.S. Pat. 1,115,238, Oct. 27, 1914; date of appl., June 24, 1912.

THE body of a bomb-calorimeter has a flat bearing rim with a square corner at its inner edge, and the cover has a flange which bears on a gasket placed on this rim. The cover itself makes a sliding fit in the top of the bomb, so as to protect the packing from the hot gases, and is held down on the bomb by a flanged collar screwed down on the body of the calorimeter. The crucible is supported by one of two parallel conductors suspended from the cover. The ignition wire is held in clips which can slide along the parallel conductors to bring the wire into a suitable position.—A. T. L.

XXIV.—MISCELLANEOUS ABSTRACTS.

Adsorption. D. Schmidt-Walter. Kolloid-Zeits., 1914, **14**, 242—252.

Davis (this J., 1907, 1217) found that when solutions of iodine were treated with charcoal the greater part of the iodine was removed almost instantaneously but that a further slow absorption continued for a long time, and he considered that the initial rapid adsorption was followed by slow formation of a solid solution. The author brings forward evidence in favour of the view that the apparent slow absorption is due to chemical reactions by which iodine is removed from solution. With benzene, toluene, and chloroform as solvents equilibrium could be attained in a very short time. In other cases, also, of slow adsorption, experimental evidence is opposed to the view that solid solutions are formed. The adsorption of acetic acid from 5% aqueous, benzene and toluene solutions and of iodine from solutions in various solvents can be satisfactorily represented by Schmidt's formula :—

$$\left(\frac{a-x}{v}\right)S = Kxe^{\frac{A(S-x)}{S}}$$

in which a is the quantity of substance present at first, x is the quantity adsorbed, v is the volume of the solution, S is the saturation value (maximum quantity which can be adsorbed), and K and A are constants. It is shown, however, that the solvent plays an important part in adsorption, and hence Schmidt's theory, in which the solvent is neglected, cannot be accepted. Acetic acid in benzene and toluene show a strong negative adsorption. —A. S.

Trade Report.

Chemicals in Algiers.

Information has been received from Algiers to the effect that there is a great opening there for chemicals. A league has been formed which is pledged to give England every preference, but unless our manufacturers will conform to the weights, measures, and terms introduced by the Germans and in customary use, it will be very difficult to secure a trade even although the demand is urgent. The Board of Trade and Chambers of Commerce have details from the Consul-General as to what is wanted, but in order to do business a personal visit is necessary. Enquiries should be addressed, in the first instance, to Dr. T. Slater Price, Municipal Technical School, Birmingham.

German chemical industry and the war. O. N. Witt. Chem.-Zeit., Oct. 8 and 13, 1914. Pharm. J., 1914, **93**, 757—758.

German works are now only being carried on for four days a week, and are suffering greatly from lack of labour, especially skilled labour. Many industries are showing greatly reduced profits, and some are working at a loss. The cessation of supplies of raw materials is one of the most important factors in the situation, but it is hoped that efficient substitutes will be found. For example, in the manufacture of sulphuric acid, the Spanish and Portuguese pyrites will be replaced by Norwegian pyrites, and should this fail, Italian sulphur could be used. The loss of Chilean nitrate is very serious, but ammonium salts will take their place in agriculture: sufficient quantities of ammonia to supplement the home production should be obtainable from Norway and Switzerland. The output of hydrochloric acid, which depends on the dye industry, will fall off, and this will affect the glass industry, which uses the sulphates so produced: it is quite possible, however, to use soda instead of sulphate in glass manufacture. The German salt deposits will be sufficient to supply the alkali and the electrolytic chlorine industries with raw material. Compounds of mercury, copper, and nickel are becoming scarce, but supplies of copper and nickel are expected from Norway, whilst the low-grade nickel ores may be able to supplement these. Chromium compounds are also scarce, owing to the shutting off of the supplies of chrome ironstone from the Caucasus.

In the earthenware industry Dalmatian bauxite or German kaolin will take the place of French bauxite, but somewhat modified processes will be required. The increased demand for iodine compounds, for use as antiseptics, is expected to be supplied by Norway. The phosphates and phosphatic manures, previously imported, will probably be replaced by German phosphatic minerals; the supply of Thomas slag will probably increase.

As regards organic products, it is anticipated that the supply will be sufficient to meet the reduced demands. The production of alcohol from potatoes and cereal grains must be limited on national grounds, but molasses and other by-products containing sugar or starch are available for the purpose. A decreased production of acetic acid is probable, owing to the stoppage of the supply of raw materials from America: the demand for acetic acid will probably be greater, and it is suggested that a suitable process will be found by which it can be produced from acetaldehyde obtained from acetylene. The peat and lignite distillation industries should do well, owing to the increased demand for benzine, lighting oils, lubricants, and paraffin. Little apprehension is felt as to the supply of benzol, but toluol and xylol will become scarce, since they cannot be obtained in quantity in by-product coke ovens. On the other hand, the production of phenol from coke ovens has increased considerably, and the supply of naphthalene and anthracene should be sufficient, owing to the diminished activity in the dyestuff factories. The dyestuff and textile industries will suffer, the former from lack of outlets and the latter from the cessation of imports of Egyptian cotton and Australian wool. The shortage of naturally occurring essential oils and camphor will in most cases be met by the increased production of synthetic products or substitutes. The industries connected with fats, oils, soap, and candles are also affected by the war, owing to the increased demand for glycerin, but it is expected that this will be effectually met.—T. F. B.

Calcium carbide; Shipments of ——. London Chamber of Commerce Circular, Dec. 9, 1914.

The Secretary of State for India in Council has decided to withdraw, during the period of the war, the prohibition of the shipment of calcium carbide in vessels carrying Indian Government stores, subject to the observance of certain regulations. The responsibility for complying with the regulations rests entirely with the shipper of the carbide.

Proposed new Customs Tariff of the Territory of Southern Rhodesia, 1914. Board of Trade J., Nov. 19, 1914. Supplement. Price 3d.

Books Received.

Technical Gas-Analysis. By George Lunge, Ph.D., Dr. Ing., Emeritus Professor of Technical Chemistry at the Federal Polytechnic University, Zürich. Gurney and Jackson, 33, Paternoster Row, London, E.C. 1914. Price 15s. net.

Volume (9 by 6 ins.), containing 394 pages of subject matter with 143 illustrations, an appendix of 5 pages, 1 page of addenda, and alphabetical indexes of names of authors and subjects. The text is grouped and classified as follows :—I. General remarks on technical gas-analysis. II. Various methods employed in technical gas-analysis. (*a*), Estimation of solid and liquid admixtures in gases. (*b*), Estimation of gases by absorption. (*c*), Estimation of gases by combustion. (*d*), Gas-analysis by optical and acoustical methods. (*e*), Separation of gases by low temperatures. (*f*). Estimation of specific gravity of gases. (*g*), Measurement of pressure and of draught. (*h*), Determination of the calorific value of gases. (*i*), Determination of the illuminating power of gases. III. Special methods for detecting and estimating various gases and vapours occurring in technical operations. IV. Analysis of gaseous mixtures produced on a large scale. V. Compressed and liquefied gases. VI. Gas-volumetric analysis.

Technical Methods of Chemical Analysis. Edited by George Lunge, Ph.D., Dr.Ing, and C. A. Keane, D.Sc., Ph.D. Volume III. Parts I. and II. Gurney and Jackson, 33, Paternoster Row, London. 1914. Brass-Furnace Practice in the United States. Department of the Interior. Bureau of Mines. Bulletin 73. Mineral Technology 1914. (Joseph A. Holmes, Director.) By H. W. Gillet. Government Printing Office, Washington, U.S.A. 1914. Price 45 cents. First edition, March, 1914.

Volume (6⅛ by 5¾ ins.), containing 289 pages of subject matter, including a bibliography of 2 pages, followed by an alphabetical index of names and subjects. There are 25 illustrations. The text is classified as follows :—I. Introduction. II. Object and method of investigation. III. General types of furnaces in use. IV. Furnace data from literature. V. Detailed results of investigation. VI. General factors affecting operation of brass furnaces. VII. Round furnaces, compared with square, pit, coal, or coke furnaces. VIII. Furnace fuels. IX. Remarks on furnace types and furnace parts. X. Possible improvements in furnaces and accessories. XI. Some furnace problems awaiting solution. XII. Advances possible with present equipment and knowledge. XIII. Causes of disease and danger, and essentials for health and safety.

DR. R. F. RUTTAN IN THE CHAIR.

COMMERCIAL HOUSEHOLD AMMONIA IN CANADA.

BY PROF. J. F. SNELL.

The inspections conducted by the Canadian Department of Inland Revenue in the enforcement of the Adulteration Act of 1886 and supplementary legislation are no longer restricted to foods and drugs, the materials which the Act was originally designed to control. Amendments to the Act and special statutes have extended the scope of the control so that it now embraces proprietary medicines, commercial feeding stuffs, agricultural fertilisers, certain paint materials (white lead and turpentine) and certain insecticides (Paris green and arsenate of lead). The extension of the scope of the Adulteration Act to household detergents would, in my opinion, not involve any more radical departure from the original intention of the Act than has already been taken, nor would it add unduly to the work of the Laboratory of the Department.

A chance observation that a package of solid "household ammonia" which had stood open for some days or weeks had lost every trace of ammonia odour suggested to me an investigation of samples of the goods, both liquid and solid, offered for sale under the name of "household ammonia," and purchased in some of the cities of Eastern Canada in 1912 and 1913. The results are set forth in the accompanying tables.

Table I. gives the cost and the results of analysis of 10 brands of clear liquid household ammonia and 5 brands of ammonia rendered cloudy by addition of soap. The differences in ammonia content shown by the various brands are, to say the least, remarkable. For comparison, the wholesale prices of two lots of concentrated ammonia are given, together with the ammonia content as shown by titration. The results for ammonia content in these concentrated samples are probably low, as it is impossible to titrate concentrated ammonia in the ordinary way without loss of gas. The specific gravity indicated about 2% more ammonia than was found by titration. Taking the results by titration, however, we see that the household ammonia sells wholesale at from 4 to 14 times the wholesale value of the ammonia contained in it. The retail price is from 6 to 20 times the wholesale value of the ammonia. The expense of bottling and packing, as well as the transportation charges on the added water, have to be included in its price, but the value to the housekeeper is in the ammonia gas alone. How much more economical it would be to buy commercial concentrated ammonia and dilute it with good soft water!

The non-volatile matter of the liquid ammonias was in almost every instance brown. In the sample which left the largest quantity of residue, however, the colour of the residue was white.

Wool dipped in the clear ammonia, dried, and re-dipped and re-dried until it had received six dippings, remained white except in the case of No. 5, which left it slightly yellow, and No. 6, which coloured it a bluish tinge. Of the cloudy ammonias, No. 12 gave a slight yellow, and No. 14 a deeper yellow coloration.

In the solid household ammonias the following determinations were made: (1) Total alkalinity by titration with N sulphuric acid. (2) Loss on ignition. (3) Non-volatile alkalinity. (4) Chlorides, by Gay-Lussac's volumetric method. (5) Sulphates, gravimetrically.

The non-volatile alkalinity was calculated to sodium carbonate, and the chlorides and sulphates to sodium salts. The difference between total alkalinity and non-volatile alkalinity obviously represents the carbonate of ammonia in the mixture, and the difference between loss on ignition and carbonate of ammonia is assumed to be water.

One would naturally expect solid household ammonia to be essentially carbonate of ammonia. Kahlbaum's ammonium carbonates, both that specially prepared for analytical use and that manufactured to conform to the requirements of the Pharmacopœia Germanica, V. Edition, were found to contain about 21·5% ammonia and accordingly to be really bicarbonate. Merck's bicarbonate has the same composition and is, accordingly, true to

name. Samples of English manufacture, kindly furnished us by Messrs. Lymans, Ltd., Montreal, and the National Drug and Chemical Co. of Canada, Ltd., Montreal, were found to contain, respectively, 30 and 31% of ammonia. Being advised by both these companies that the English-made carbonate would undoubtedly be used by Canadian manufacturers of household ammonia, we have calculated our volatile alkalinity to a carbonate of ammonia containing 30% NH_3.

According to our analysis, none of the brands of solid household ammonia contained as much as 10% of commercial carbonate of ammonia. One of them ran as low as 2%. The chief constituent was in all instances sodium carbonate, but sodium sulphate ran as high as 13½% in one brand. In estimating the wholesale value of the mixture we have allowed one cent. per pound for the carbonate but nothing for the sulphate, which is worse than useless in a washing compound. The contrast between cost of materials and selling price is not so great as in the case of the liquid preparations, doubtless on account of the lower cost of containers and lower transportation charges. But these solid preparations are clearly "misbranded" and fraudulent.

New England Section.

Meeting held at Engineer's Club, Boston, on Friday, November 20th, 1914.

MR. ALAN A. CLAFLIN IN THE CHAIR.

THE POSSIBILITY OF ESTABLISHING A COMPLETE DYESTUFF INDUSTRY IN AMERICA.

BY DR. D. W. JAYNE.

There has been up to the present time no complete dyestuff industry in America, because hitherto there have been no economic reason for it. The producers of the crude materials had no excess and no other incentive, and the consumers of the dyes offered no inducement, their demands apparently being met satisfactorily by imports.

Until the advent of the by-product coke oven the production of coal tar increased but slowly, being entirely from plants producing coal gas. The first recovery oven in this country was established by the Semet-Solvay Co., about twenty years ago, though at that time by-product ovens abroad were an accepted fact. Besides this, the coal tar from gas plants has always been a factor abroad, especially in England, where as late as 1900 the gas tar alone was more than twice the oven tar of Germany, and seven times the combined production of both gas tar and oven tar in the United States. The small quantity produced in the United States in 1900 was due to the fact that so many plants here manufactured carburetted water gas, the tar from which is not included in these figures, that the tar from coal gas was and still is an exceedingly small item, and even in 1900 the number of recovery ovens was small—the rapid installation period coming after that date. Europe had many years' start of us, because they began to see the desirability, and perhaps the necessity, of providing outlets for the various coal tar products, while we, up to the present time, have found no difficulty in disposing of those coal tar products which might enter into the manufacture of dyes. As a nation we are not apt to plan far in advance, and the tar distiller did not give much thought to the dyestuffs under the existing conditions. The same condition held true in England, for England has no complete dye industry. Germany developed the coal tar dye industry, using not only its own materials but many brought from England, until it has become one of the most complete industries in the world. The German dye manufacturers have also had every advantage of government aid in their development, and they present a united front to all competition. Here, the construction of by-product ovens has gone on until to-day about 25% of the coke is produced in them, and still we have not produced a surplus of coal tar products which could be used for dyes.

The products, which are the basis for dyestuffs, are benzol, naphthalene and anthracene. Benzol and its homologues, toluol and xylol, occur in coal tar in small quantities. The chief source of benzol is the coke oven gases. The Semet-Solvay Co., besides installing the first recovery oven in the United States, also established the first benzol recovery plant in connection with their ovens. They now recover at all their plants, and are the sole producers of that which is available for refining to-day. Several other oven installations which sell gas to cities do remove the benzol from the fuel gas, but use it to enrich illuminating gas. The Semet-Solvay benzol is also used for enriching at some points, so that it is not all available for refining; but even so, there was a surplus of benzol less than two years ago, and the shortage to-day would be less marked had it not been for the depression in steel. Few consumers of benzol realise how fluctuations in steel affect supplies of benzol, but with the lessened demand for coke, less coal is coked, with consequently less by-products.

We are already independent of Europe—negligible quantities only of benzol have been imported during the past few years—the price levels here and abroad being approximately the same. The demand abroad is also heavy, due to the use of benzol for motor fuel, especially during the recent high price of gasoline.

Toluol is of more importance to the nation on account of its use in the explosive field than in the manufacture of dyestuffs, and an increase in supplies of benzol brings increased supplies of toluol, which will help the situation in the manufacture of explosives for our national defence.

An increase in benzol supplies will also make it possible to manufacture phenol synthetically. Phenol is to-day produced in the United States in less proportion to the country's consumption than any of the chemical bodies occurring naturally in coal tar. Our small production of phenol from our tar is primarily due to the small proportion of gas tar produced here, because the tar from coke ovens is deficient in true phenol. England has always been the great factor in phenol, simply because of its large production of tar from coal gas plants.

Naphthalene, the second crude base, occurs in considerable quantities in coal tar. Until recent years the distillate from coal tar in the United States was taken off in only two portions, light oil and heavy oil; the balance, pitch, remaining in the still and the oils taken off to that point which left the correct grade of pitch. This means that pitch was the primary product sought for, and in fact remains so to-day. This is not to be wondered at, since coal tar yields on the average 70% of pitch, used for roofing, paving and waterproofing; and the American tar distiller began, and has remained, essentially a manufacturer of roofing and paving materials. This is quite different from conditions abroad, where practically their only use of pitch was for fuel purposes, until the advent of its use for road construction, which is of recent date. Credit is due to the American tar distillers for their efforts in building up a big business for pitch, this 70% of all the tar—and for that reason we make a distinction between the coal tar industry, which is an American development, and the coal tar *chemical* industry, which is exemplified by the German production.

The heavy oil as produced here was sold just as produced, for creosoting timbers. In it was the naphthalene, and most of the tar acids, notably cresol, and with the ever-increasing demand for creosote oil, there was no reason for reducing the amounts available by removing naphthalene from it. Moreover, refined naphthalene has always come into this market at prices so low that it did not pay the tar distiller to remove and refine it. Certainly no more profit could be obtained by so doing than by its sale in the creosote oil, and large plant investment is required for the separation and refining of naphthalene.

Refined naphthalene has been produced here, however, for many years—practically since the beginning of tar distillation in this country, and our present production of it is nearly one third of the country's consumption. But it is nearly all used as a moth repellent—not, any as far as I know, having been used for the manufacture of any product entering into the dyestuff industry.

Conditions have altered somewhat in the past few years. Specifications have been drawn up for creosote oil which eliminate the lower boiling portion, and now an increasing quantity of middle oil is being separated and the naphthalene and tar acids recovered from it. More naphthalene can be recovered and refined, and no doubt will be, if a demand is assured, at a price commensurate with the added investment and cost of manufacture.

The separation of anthracene from the heavy oil is not now carried on in the United States. About thirty years ago there was a plant which separated small quantities of it for export, but this became no longer remunerative and was discontinued. It is now left in the creosote oil, but the quantity which could be obtained is a much less proportion of the tar than is recovered abroad, because all their tar is run to hard pitch, which is the grade used for fuel, that is, briquettes, while as explained, we run, in the United States, for soft pitch. Thus, some of the high boiling oils containing anthracene remain in the pitch. Some hard pitch is made here, however, and if a steady demand arose at a price commensurate with the investment and manufacturing cost, anthracene could be recovered probably in sufficient amounts for the needs of our dyestuffs.

It is well to remember that less than 10% of tar consists of bodies which can be used for making dyestuffs, the balance being neutral hydrocarbon oils sold, even by Germany, for creosoting purposes only.

It is true we have an American coal tar dyestuff industry. Nearly 20% of our consumption is manufactured here, but until three years ago all the dyes made here were from imported intermediate products; or else were imported in a condition requiring only slight alteration to make them suitable for the trade.

In 1910 the Benzol Products Co. was formed. This company had as a central thought the fact that some day a very considerable amount of benzol would be recovered here, and that it was an opportune time to start operations in order to be ready to take advantage of those conditions when they arrived. Therefore the manufacture of nitrobenzol and aniline oil was undertaken. Thirty years ago the Schoellkopf plant, at Buffalo, had made aniline oil, and more recently the Barrett Manufacturing Co. had tried the manufacture of aniline and toluidine, and had a small plant which, however, had been used almost exclusively for toluidine, as toluol had been a drug on the market, its use for explosives, such as trinitrotoluol, not yet having been started. This previous experience had demonstrated the large part played by sulphuric and nitric acids in the manufacture of aniline oil, many more pounds of acid than of benzol being required for the manufacture of aniline oil; so that in the formation of the Benzol Products Co., the manufacturer of acids was represented. This same condition is evidenced in the plants in Germany, which have built themselves around and in connection with the manufacture of acids, alkalis and heavy chemicals in general.

Since the Benzol Products Co. began it has perfected its manufacturing operations, and no doubt exists as to the quality of the product. The quantity, however, has been limited, primarily, because of the efforts of the foreign convention to nip its operations in the bud, and secondly, because of the shortage of benzol which was felt soon after it was in position to expand. Under these conditions it was deemed unnecessary to sacrifice any more benzol than was necessary to take care of those few buyers who had given visible evidence of their desire to encourage this American industry.

Here we see the attitude of the American consumers of dyestuffs. They were being supplied, at comparatively low prices with a wide variety of dyes, continually improved as to fastness and new shades. They were buying direct from the representatives of the great German firms: why buy one item such as aniline oil from us especially as every offer as to price from us was bettered by their present suppliers? In fact, when a 10% duty on aniline oil and salt was secured in the recent tariff, the European Convention not only absorbed that duty, but made lower prices than before. There were several notable exceptions to this condition, and among them were several of the American dyestuff manufacturers. They no doubt realised more than the consumer how utterly dependent the United States was on foreign makers for our supplies of dyes. For them we continued to make aniline, but that was not enough encouragement to warrant any expansion, so that the outbreak of the war found us still only manufacturing aniline oil, and not enough benzol in sight to warrant immediate steps to enlarge so that we could at least supply the country's demand on that one item.

The reason why we had not a better established and more complete dye industry years ago was essentially a matter of international economics. The United States had no surplus coal tar products to dispose of, and no incentive in additional profits if it did offer refined products to dye makers, as the intermediate products such as aniline oil, beta naphthol, etc., as well as the hydrocarbons themselves, such as naphthalene and anthracene, could be imported more cheaply than the tar distiller cared to attempt to make them. The manufacturers of dyes themselves had to meet very keen competition. In 1880 there was a sufficiently high duty on these dyestuffs and no duty at all on the intermediate products, so that at that time the dyestuff industry, based on imported intermediates, began to thrive; but in 1883, the specific portion of the duty on dyes was abolished, and a considerable duty assessed on the intermediate products, and as such intermediate products that far back could not be produced in this country, primarily on account of shortage of supplies at that time, many of the established factories closed down shortly after. There was again a period during which the intermediate products came in free, but the experience was evidently sufficient to prevent any resumption of this industry by the erection of any new plants, and the few factories who have stuck to their manufacture during the varying periods have made but little profit.

The possibilities and prospects primarily depend on the consumers of dyestuffs. Do they want an American dyestuff industry? Are they willing to help pay the price needed to establish it, and if so, will they come forward and say so?

In the first place, there is sufficient coal tar produced in the United States to-day to give the necessary quantity of naphthalene and anthracene to supply our needs of dyes made from it. Plants to recover them could be erected as soon as plants to use them can be.

Benzol exists in by-product coke oven gases in quantities far exceeding the present needs of both the dyestuff requirements and the trades consuming benzol as a solvent. Efforts have been made, ever since a shortage was seen to be inevitable, to secure the erection of additional recovery plants, but little of the possible supplies can find their way to the dyestuff manufacturer and the other outlets are the controlling factor. However, there seems good reason to hope for partial relief during the next year at least to an extent sufficient to enable the manufacturers of aniline oil to increase their production. It takes time to demonstrate to the owners of the ovens the advisability of investing in such a recovery plant, especially steel companies in times of depression as have existed, and it takes just as long to get the plant erected after the preliminaries are disposed of.

Any thought of prompt relief in the dyestuff situation is out of the question. We can have the whole complete industry for future use, if the consumers want it, but without a strong plea from the consumers, neither the tar distiller, the manufacturer of intermediates, nor the manufacturer of dyestuffs will risk the large amount of capital necessary.

To establish such an industry, to protect the country from a future shortage requires one thing and one only; that is, adequate protection. Adequate protection means a higher duty on *all* dyes, and one-half the duty on dyes to be assessed on intermediates, and it also means protection against competitive methods which are aimed to crush and with which we have had experience. This latter protection can probably be best secured by a proper anti-dumping clause in our tariff.

Nothing else is necessary. We have the materials, we have the technical knowledge, we have the capital, we have sufficient unpatented dyes to make nearly everything actually needed, but we need protection.

The need of protection against unfair competition is obvious, but is the need for a higher duty equally so? Bearing in mind that we have no surplus products as yet, it must be made more profitable for the tar distiller to separate and refine the products needed than to leave them as they are to-day, to be sold in the oils. This means higher prices to the dye manufacturers and they, therefore, need some offset to enable them to sell their output in competition with the imported dyes. This immediately suggests the thought of the ultimate result on the price of materials if dyed with the higher priced dyes. I have been assured that the price of the dye itself is an absolutely negligible item in most costs of finished goods, and cannot possibly affect the price to consumers, and therefore puts the question directly before the users of the dyes. It is a question for them to answer whether they want an American dyestuff industry independent of Europe and are willing to pay the price to have it.

My personal opinion is that the additional price necessary to be paid by the users of dyes, in order to secure this industry, would not be a permanent increased cost. Tariff protection during the period of development only should be considered. Such an industry would be competing with one of the strongest and richest industries in the world, and competing only on products which are free to all as regards patent restrictions, while the German industry has made vast sums on its products during the life of the patents and continues to reap large profits on those items on which the patents have not yet expired. This means competing on those items which are now sold on close margin and having no exceedingly profitable items which have helped the Germans to earn their immense profits. Protection over a term of years to protect a growing industry has already been given by this government. The often cited example is the tinplate-industry, which was given assurances of a continuing protection for at least ten years, and whose development was immediately begun with that promise. To-day it is certainly able to hold its own with anyone. The same would be true of a dyestuff industry.

The initiative lies with the consumers of dyes. Will they make it plain to Congress that they want an American Coal Tar Dye Industry?

MR. JOHN WHITE IN THE CHAIR.

THE WORK OF THE PUBLIC ANALYST IN RELATION TO MANUFACTURED PRODUCTS.

(CHAIRMAN'S ADDRESS.)

(*Abstract.*)

The object of the address was the discussion of certain points, connected with the preparation or manufacture of articles of food, which arise from time to time in the administration of the Sale of Food and Drugs Acts, and upon which the views of the Public Analyst and the manufacturer do not always coincide.

For example, a matter upon which the Analyst and the manufacturer or trader not infrequently disagree, is the policy euphemistically called "trade custom." This term covers a somewhat wide field, and a multitude of sins, and may include among other practices: (1) the substitution of some article for the particular article asked for by a purchaser, as for example the sale of tapioca as sago; (2) methods of bleaching, dyeing and colouring, as the bleaching of flour, the dyeing of beet-sugar to imitate Demerara sugar and the colouring of milk and butter; (3) the addition of substances known as "improvers," as phosphate of lime and potassium persulphate to flour; (4) methods of "facing" and polishing, such as the facing of rice or pearl barley with talc or French chalk; (5) "grading" articles during their preparation, with the object of leaving in the finished material an undue proportion of some worthless or semi-worthless ingredient, such as cocoa shell in cocoa, pepper husk in pepper; (6) the sale of mixed articles under the name of the article they purport to represent, with an attached label, printed in microscopical characters, notifying the admixture: examples, mustard mixed with starch and turmeric, cocoa mixed with sago and sugar; (7) the addition of salicylic acid as a preservative to unfermented wine.

From this list it may be gathered that gross methods of adulteration are declining, and in fact adulteration is rapidly becoming a scientific operation, carried out methodically by the manufacturer on lines laid down by his chemical advisers.

In further illustration was mentioned the article known as milk-blended butter, a substance originally prepared by blending milk with butter, the product containing some 25% by weight of water, and commanding a large sale under its somewhat alluring name. The Butter and Margarine Act prohibits the use of this name, and the article must now be sold under a fancy name approved by the Board of Agriculture, while the percentage of water, limited to 24, must be stated on the label.

A further notable step was the use of coconut oil, a fat possessing a considerable proportion of volatile fatty acids, as a butter adulterant, and a skilful blend in the right proportions of this and a neutral fat, such as lard, with butter gave a mixture answering to some of the tests for genuine butter.

These practices have been restricted by the Butter and Margarine Act, which gives the Board of Agriculture power to inspect butter factories, that is, places where butter is re-worked or blended, and enforces their registration with the Local Authority for the district. This Act also makes it unlawful to manufacture, sell, expose for sale, or import any margarine, the fat of which contains more than 10% of butter fat. So the death-knell was sounded of the mixtures of about half butter and half margarine which could only have been prepared with fraudulent intent, and which were calculated to deceive even the expert.

The sale of "filled cheese" or margarine cheese as cheese is now rare, but cheese gravely deficient in fat is fairly common, no standard for this existing. The writer has found Dutch cheese containing 1·5% of fat and 56% of water, and when this had dried naturally, it required a hammer and chisel to cut it. It was an ingenious idea to "coat" Gorgonzola cheese with an artificial rind made of barium sulphate coloured pink with oxide of iron, and rendered plastic with tallow; such a rind sometimes weighed one-fifth of the total weight of the cheese.

Rice is "faced" with talc or French chalk in order to polish or glaze the grains, and a limit of 0·5% of such extraneous mineral matter is usually held to be permissible. In the opinion of the writer such "facing" should be entirely prohibited, and as rice itself generally contains only about 0·3% of total mineral matter, the above limit seems unduly liberal. Already this method has been extended to pearl barley, which is also sometimes faced with mineral matter, though the latest idea is to dress the grains of pearl barely with rice flour, a method now largely practised in Holland.

The objectionable practice of bleaching flour by exposure to nitrogen peroxide admits of the use of low grade wheats which ordinarily yield a yellow flour, and thus an enhanced price may be obtained for an inferior article. An equally objectionable trade custom is the addition to flour of "improvers," generally consisting of acid phosphate of lime, phosphoric acid, or potassium persulphate. The object is to increase the "strength" and water absorbing capacity of flour, and bakers are informed that as many as 10 to 14 extra 2 lb. loaves can be obtained from a sack of flour by the addition of about 2 lb. per sack of 280 lb., with of course a corresponding diminution in the actual amount of flour in each loaf, and consequently in its nutritive value.

These processes have long engaged the attention of the Local Government Board and references have been made in reports upon the work of their Inspectors of Foods. It has been shown by these reports that bleaching was found to exercise an inhibitory effect on the salivary digestion of flour, and attention is drawn to the possibility that the changes which occur in the oil and protein during the process may have a prejudicial effect upon the nutritive value of the flour.

In the Report for 1912—13 the following significant passage, dealing with the addition of "improvers," occurred :—" It is a matter for concern that food materials should be liable to admixture with foreign substances of questionable wholesomeness and of no utility from the point of view of the consumer, merely for the purpose of securing trade advantages. This is especially so when an article of food is concerned like flour on which the bulk of the nation depends to a large extent for its nutrition. In such a case the community cannot afford the risk involved in any addition to or alteration of the food material which may at all impair its nutritive qualities."

It is sometimes asserted by the trade that these methods of bleaching and grading to produce a lighter colour are due to the necessity of meeting the demand of the public for whiteness, but the probability is that the public taste has really been trained in accordance with the wishes of the trade, by whom the whiter articles have been pushed forward. In what other way could the custom have arisen of the almost invariable substitution of tapioca, which is white, for sago, which is brown?

Other methods of sophistication to be noted are the packing of sardines in cotton seed oil in substitution for olive oil; and baking powders yielding only 1 or 2% of available CO_2 and which are therefore practically worthless.

A Court of Petty Sessions cannot satisfactorily settle the many complicated legal and scientific points arising in the administration of the Acts, and a Court of Reference, as recommended by the Select Committee on Food Products Adulteration, is now more urgently required than ever. Such a body would constitute an advisory Board to whom difficult questions requiring adjustment would be referred.

Very brief reference may be made to the Fertilisers and Feeding Stuffs Act. A point of material value to the purchaser is that the Act makes it obligatory for the seller of feeding stuffs, subject to certain exceptions, or of fertilisers, to state in his invoices the respective percentages of oil and albuminoids in the one case, and the percentages, if any, of soluble and insoluble phosphates, nitrogen and potash in the other, and that these percentages take effect as a warranty that the actual composition of the goods sold does not differ from the stated figures beyond certain official "limits of error." Generally manufacturers are found to comply loyally with these requirements, delivering an article in accordance with the terms of the guarantee. It is indeed striking to find how remarkably constant in composition some of the brands of oilcake are becoming, evidencing accurate standardisation of the methods of manufacture. Thus the original argument of the trade, that it would be difficult to give even an approximate guarantee for such goods, is refuted by their own improved methods, and it is open to question whether the "limits of error" might not with advantage be made a little more stringent.

DISCUSSION.

Mr. S. J. **PENTECOST** asked whether cotton-seed oil was less nutritive than olive oil. The hydrogenation of some oils was said to make them fit for use in the manufacture of margarine and other products.

Mr. T. F. **HARVEY** asked whether sardines in cotton-seed oil were sold at a lower price than those in olive oil. It seemed to him that the prejudice to the purchaser could only be a financial one. In the new Pharmacopœia what was known as the "Indian and Colonial Addendum" would be included, permission being given at any rate in our Colonies to use either arachis or sesamé oil in the place of olive oil in certain preparations when it was desirable to do so.

Mr. J. H. **DUNFORD** referred to the large quantities of degelatinised bones used by the makers of so-called baking powders and also in the manufacture of phosphated substances used by bakers as adulterants to give more body to flours. The method prescribed by the Fertilisers Act, of classifying as unsatisfactory all manures which did not conform to the guaranteed analysis, within the prescribed limits of error, was not fair nor equitable to the manufacturers. Both those fertilizers under and over the guarantees were classed together as unsatisfactory.

Mr. C. E. B. **MERRIMAN** said in a recent case, pepper had been represented to contain an abnormal amount of husk. As a matter of fact it was graded, one portion containing a large amount of husk and another portion a large amount of pepper starch, but both contained the same amount of the pungent principle. Should both portions be treated as adulterated?

Mr. W. G. **TIMMANS** mentioned that he had a customer who objected to sulphuric acid being water white and he had to darken it. Farmers often objected to having white bone manure, thinking it was adulterated; the real reason was that the benzine method of treating bones extracted the whole of the grease which was formerly not extracted.

Mr. J. M. Wilkie asked why a certain amount of discrimination was allowed to the vinegar manufacturer while similar liberty was denied other manufacturers. In regard to food products, he thought many people genuinely desired whiteness. Bearing in mind that flours might naturally contain nitrites, had it been definitely decided that nitrite-bleached flour, when the process was not carried to excess, was harmful to the organism ?

Mr. White said that he objected to manufacturers and traders setting up so-called trade customs with the view of giving the public an article that the public did not ask for, and doing this repeatedly until the custom became perpetuated. For long the custom of packing sardines in olive oil had existed, but if the manufacturers packed them in cotton-seed oil, the public had cause of complaint. Successful prosecutions had already been instituted for this offence. The question was not whether cotton-seed oil was as nutritious as olive oil, but whether the purchaser was getting what he asked for. In his own opinion he was not. Then with regard to the hydrogenation process, if a malodorous oil could be converted into a white solid odourless fat he had not the slightest doubt it would soon find its way into margarine. The bulk of margarines had coconut oil as their basis. The Fertilisers and Feeding Stuffs Act stated that the article sold must be in accordance with the guarantee stated in the invoice, subject to certain official limits of error. Tapioca and sago were absolutely different; tapioca was obtained from the root of *Manihot utilissima* and sago from the pith of the sago palm; when the substitution of tapioca for sago began it was because at that time, as now, tapioca was cheaper. He was not surprised that farmers objected to white manures if the colour had been grey before, because farmers were ultra-conservative. He did not think that in the first instance the public demanded a white article; it was simply because they had been educated in accordance with the wishes of the trade. The Local Government Board had made the statement, based on the evidence of Dr Monier Williams and Dr. Hamel, that bleached flour did interfere with digestibility, and had it not been for the war a Bill would in all probability have been introduced into the House of Commons one of the main features of which would have been the control of these methods of bleaching and of adding " improvers " to flour.

Mr. Archbutt remarked that there had been a great shortage of olive oil for several years and there was not sufficient to meet the various requirements. Unless it could be shown that cottonseed oil was less nutritious and less useful than olive oil for purposes of that kind, he did not see any reason why the substitution should be objected to, provided, of course, that the fact was stated.

Meeting held at Leeds, Queen's Hotel, on Monday, November 30th, 1914.

MR. F. W. RICHARDSON IN THE CHAIR.

THE ANALYSIS OF TANNING MATERIALS.

Part I. An Improved Basic Chloride Shake Method.

BY HUGH GARNER BENNETT, M.SC.

It is now nearly eight years since Procter and Bennett published their basic chloride shake method for the analysis of tanning materials, and that method—with trifling modifications—is still in use as the official method of the I.A.L.T.C. It is a considerable tribute to the method that during the last few years little or no alteration has been made to it, and that no marked improvement upon it has yet been suggested.

The shake method as used at present was a great step towards truth. The great number of comparative analyses now available show beyond dispute that the shake method estimates more non-tannins and less tannin, and is therefore so far nearer the actual truth.

At the same time the present official method does not yet properly distinguish between the tannin and non-tannin content of tanning materials, there being still a considerable proportion of non-tanning matters absorbed by the hide powder and reported as tannin. This has been conclusively demonstrated by the analyses of artificial mixtures, as in the experiments of Procter and Blockey [Collegium, 1903, 114, 124], and of Parker and Bennett [this J., 1906, 1193]. In the case of some non-tannins, especially of the gallic acid and catechin type, the error even with the present method must be very considerable. Therefore any further improvement in the method of tannin analysis should be in the direction of higher non-tannin results, and in consequence, lower results in tannin. What leather chemists must continue to search after is a method which detannises easily and yet yields a higher percentage of non-tannins. Important financial interests are involved in this matter, but as long as leather chemists are using a method of analysis which does not yield the actual truth in its results, they must continue their endeavours to improve their method of analysis in such a way as to approach that truth. What is desired is not to estimate leather-forming value, but to determine the percentage of " tannin " in a material, whatever the nature and quality of that tannin. The tannins are a pretty definite group of compounds, and there is no doubt as to what is included in the term. Their relative leather forming value and the leather forming value of some non-tannins are certainly questions not to be forgotten, but are quite distinct from the question of the estimation of the amount of tannin.

Naturally those who sell tanning materials, especially tanning extracts, will not welcome changes which show less tannin present in those materials, but any change towards truth would apply generally; it is only those who have inferior materials to offer, who have any real need to fear an improved method of analysis. Further, it is urgently necessary from the tanners' point of view that any positive improvement and advance towards truth should be adopted as soon as possible.

The question is therefore: *what alterations in the official method will give equally good (or better) concordance, and yet estimate less tannin ?* How can the absorption of non-tannins by hide powder be lessened ? Some previously published experiments by the author supplied a hint towards the answer. In a paper on " The Standardisation of Hide-Powder " [this J., 1907, 455], the influence of the texture and acidity of the powder itself was pointed out, and the importance of the acidity due to chroming was emphasised. Procter and Bennett [this J., 1906, 1203] also pointed out the influence on results of the amount of moisture added with the powder, and hence suggested a fixed amount. On similar grounds they suggested a fixed amount of hide powder. The question arises, therefore, whether the amounts fixed a few years ago were the best, and whether by a judicious alteration we might not be able to show (by substantially the same method of analysis) a distinct improvement in accuracy. The writer now suggests that the shake method would give lower tannin results, and higher non-tannins if modified in any or all of the following ways:—

1. Decreased acidity in the hide powder before chroming.
2. Detannisation in a more dilute infusion.
3. The use of less hide powder.
4. Decreased acidity in the hide powder due to chroming.

1. *Decreased acidity before chroming.* In a previous paper by the writer experiments were recorded with hide powders with acidities up to 12·6, as determined by the method suggested in the same paper. The great influence of this factor on the results was emphasised, and it was demonstrated that the more acid powders gave much lower non-tannin results. It was further pointed out that "if a large quantity of acid were in the powder it would be necessary to have some method of controlling it in the washing, for it would be useless to fix a definite acidity in the unchromed powder, if an indefinite proportion is to be washed out." It is nevertheless precisely this futile method that has been adopted by the I.A.L.T.C. As a first limit, the author suggested an acidity of 5·0 as a *maximum*; later A. T. Hough pointed out that hide powders with greater acidities could be brought down to 5·0 by the addition of the required amount of caustic soda solution; but more recently, on the plea of concordance, the I.A.L.T.C. have adopted the method of acidifying more neutral powders to bring their acidities up to what was previously a maximum. As pointed out above, this cannot be conducive to concordance. If a few c.c. $N/10$ HCl are added to the powder before chroming—how much of this will be left in after washing?

The ordinary test for chlorides in the wash waters is no guide at all. That test was devised as an indication of the rate at which salt (NaCl) was being washed out of the powder. This was just a matter of repeated dilution until its concentration was negligible. Washing free from chlorides when the powder is acidified with hydrochloric acid is another matter altogether. That is a matter of hydrolysis, not of dilution, and in the hands of different operators is liable to be carried out to a widely different extent, with the inevitable difference in the results. The effect of acidifying the hide-powder up to 2·5 to 5·0 acidity has simply been—

1. To render the washing test of little or no value.

2. To give lower non-tans, and higher results in tannin.

3. To produce discordant results between different operators.

If the I.A.L.T.C. think the time is ripe for so standardising the powder that its acidity should be definite and universal, it seems clear that the amount to fix on should be nil. The suggestion of Hough should be carried a stage further, and the powder made neutral by the addition of the required amount of $N/10$ NaOH solution. This would restore the value of the washing test for chlorides, would give far better concordance than acidified powders, and would also contribute towards the object of this investigation, viz., more accurate results. The experiments recorded below confirm completely the author's statement of eight years ago that neutral powders when chromed as usual will detannise as easily and as completely as acid powders. If that be so, what need is there for any acid? It would be perfectly satisfactory to rely solely upon the acidity due to chroming for the attainment of complete detannisation.

Neutralised powder is much easier to manipulate than acidified; it is easier to detach from the linen, easier to wash, and very much easier to squeeze. With acidified powder a press is practically a necessity, but with neutralised powder it is quite unnecessary.

2. *Detannisation in a more dilute infusion.* In the original paper of Procter and Bennett [this J., 1906, 1203] the amount of water to be added with the hide powder was fixed at 50 c.c. to 100 c.c. liquor. To avoid a factor this was later changed to 20 c.c., making the total volume of liquid 120 c.c., of which, half (60 c.c.) were evaporated for weighing. It was observed that when the total volume was made up to 150 c.c. the non-tans were slightly higher than when the total volume was 120 c.c., *i.e.*, if the determination be conducted in a more dilute infusion, there is a lesser absorption of non-tanning matters. In the present work it has been sought to dilute the infusion as much as could be done conveniently, and by adding 100 c.c. distilled water to 100 c.c. liquor, and mixing gently before adding the hide powder for shaking. With the powder 20 c.c. water are added as usual, and in this case the total volume is 220 c.c., of which half, 110 c.c., are evaporated by pipetting successively 60 c.c. and 50 c.c. of non-tan filtrate. This may be done in the usual basin, or, if desired, in special basins to contain 110 c.c. The influence on the results is very marked, as will be seen from the figures below.

3. *The use of less hide powder.* In considering the standardisation of hide powder, stress was laid on the influence of the texture of the hide powder on the result, and comparative work showed that granular powders gave higher non-tannins than fibrous powders. This was doubtless to be explained by the greater surface action of the fibrous powder. Although truer results are yielded by the granular powders, they were ruled out for the sake of general concordance, and also to obtain a closer agreement with the results of the American chemists, who used fibrous powders.

In the present investigation, which seeks only to approximate to truth, another alternative presents itself. If less surface action be the cause of the difference between granular and fibrous powders, it would be an easy matter simply to reduce the amount of hide powder used, so obtain less absorption (or adsorption) of non-tanning matters. The present amount, 6·5 grams dry powder per analysis, was at the time of choice the *maximum* amount used by the American chemists, and was fixed upon by Procter and Bennett to make concordance more certain.

There seems no doubt now that this amount is quite unnecessarily large, and that complete detannisation can be obtained by 5 grams dry powder per analysis, and possibly even less.

A common criticism of our method of analysis has been that in analytical work the hide powder is in distinct excess over the tannin present, whereas in the tannery the tannin is in excess of the hide. Perhaps this criticism will always have some force, for analysis must do its work in a comparatively short time, yet there is every reason to make the difference as small as possible. Less hide powder would mean that the analysis was carried out nearer to tanyard conditions. On this principle, as well as to obtain higher non-tannin results, it is highly desirable that in analysis the hide powder should be in the least possible excess.

The experiments here recorded show that this factor has less influence on the results than might be expected, but it clearly has an influence, and in the required direction. In working with a decreased amount of hide powder the writer observed the convenience involved in such a change. The smaller quantity of powder was more convenient to manipulate, and much quicker to wash. The saving in cost (23%), as well as time and trouble, would be considerable in many laboratories. In short, therefore, less hide powder means truer results, in less time, with less trouble, at less cost.

4. *Decreased acidity due to chroming.* Even the basic salt $Cr_2(OH)_3Cl_3$, which is now in use for chroming, is considerably acid, and it was decided to test the effect of chroming with a more basic salt, and so reducing the acidity due to chroming. The influence of acidity before chroming is considerable, and there seemed no reason to expect the contrary in the acidity due to chroming. This indeed proved to be the case. The chromic chloride for the present experiments was made basic to correspond to the salt $Cr_2(OH)_4Cl_2$. For a few experiments only 1·89 c.c. $N/10$ sodium carbonate may be added to each 1 c.c. of the ordinary 10% stock solution of $Cr(OH)_3Cl_3$. As anticipated, the non-tannins obtained were distinctly higher when the more basic salt was used, and yet the solution was quite satisfactorily detannised. The powder was much more easily washed free from chlorides.

The following experimental results were obtained by testing the same sample of a good chestnut extract in various ways, and illustrate the influence of the various factors discussed above. The results are each a mean of two very closely agreeing duplicates:—

	Method used.				% Non-Tans
	Acidity before chroming.	Amt. of hide powder per "shake."	Total vol. of detannised solution.	Chroming salt.	
One factor changed	5·0	6·5	120 c.c.	$Cr(OH)_3Cl_3$	11·8
	5·0	6·5	220 c.c.	,,	12·9
	0·0	6·5	120 c.c.	,,	12·6
	5·0	6·0	120 c.c.	,,	11·9
Two factors changed	0·0	6·0	120 c.c.	,,	12·6
	0·0	5·5	120 c.c.	,,	12·6
	0·0	5·0	120 c.c.	,,	13·0
Three factors changed	0·0	6·0	220 c.c.	,,	13·4
	0·0	5·0	220 c.c.	,,	13·9
Four factors changed	0·0	5·0	220 c.c.	$Cr(OH)_4Cl_2$	14·9

In each of these experiments the solutions were quite completely and satisfactorily detannised, and the absorption of tan took place with the same case as in the I.A.L.T.C. method. It will be seen that when all tho factors are changed that have been discussed above, the difference from the I.A.L.T.C. method is about 3%. Other extracts and other materials show other differences according to the nature of the material and the quantity of non-tanning matters associated with that particular material.

By altering the above four factors farther in the same sense, it should be possible to obtain still higher non-tannins and still more correct results. If the alterations be carried far enough, of course, the time will come when detannisation will become incomplete. The most correct results will be obtained when these changes are strained almost, but not quite, to the breaking point. What exactly this point will be depends largely on which factor is pushed to the extreme limit. The author, however, regards a further reduction of hide powder to even less than 5·0 grams per shake as the next most desirable step. It is intended to make further experiments on these lines. It is possible that the attainment of the minimum amount of hide powder may involve some extension in the time of shaking. The author would therefore suggest that the basic chloride shake method should be revised officially, and carried out with the following modifications :—

1. The hide powder to be exactly neutralised before chroming.
2. Only 5·0 grams dry hide powder to be used instead of 6·5 grams per analysis.
3. To 100 c.c. ordinary strength infusion, 100 c.c. of distilled water to be added before the prepared hide powder, and the total volume made up to 220 c.c., of which any convenient aliquot part may be evaporated for weighing, preferably 110 c.c., as its use involves no "factor."
4. The chroming liquor to be a solution of the salt $Cr_2(OH)_4Cl_2$ instead of $Cr_2(OH)_3Cl_3$.

These alterations, though perhaps not as near the truth as it is possible to get, would at any rate be a distinct step towards that goal. Though still within the limit as to what is possible in improving the method of analysis, they might well be made part of the official method of analysis as another step towards the ideal method.

It still remains to satisfy "Concordance." The author's own experience with the revised method leads him to expect no difficulty in this direction. The same material analysed in duplicate in successive days has given the same results. There is, however, no perfectly satisfactory way of testing the concordance of a method except by collecting the results obtained by independent observers in different laboratories, and the writer therefore cordially invites collaboration in testing this method. Although the writer considers this revised method well within the limits of complete detannisation, it is just conceivable that with some particular test a trace of tan may be left unabsorbed. Any method which seeks to be nearer the truth must risk this to some extent. If incomplete detannisation should be observed in any instance the defect can easily be remedied. In all the experiments hitherto the usual 15 minutes' churning has been given, but some experiments undertaken in conjunction with Mr. J. R. Blyth a few years ago indicated that the extension of the time of churning has little or no effect on the absorption of non-tannins and upon the result. By extending the time of churning 5 or 10 minutes' complete detannisation together with all the advantages of the improved method could still be easily ensured.

If the objection be urged that the revised method needs longer time for the evaporation of 110 c.c. instead of 60 c.c. it may be pointed out that on the other hand time is saved in washing the powder, which needs more personal attention. Again it is questionable whether the result of the analyses would be at all retarded, for at present the "non-tannins" are quicker to finish than the "total solubles," owing chiefly to the much less time required for drying to constant weight. Further, it is possible that the time required for a whole analysis could easily be shortened by reducing the time for chroming hide powder, the one hour specified is unnecessarily long, especially with the more basic chroming liquor now suggested. In conclusion, it may be of interest to give a few comparative analyses with different tanning materials. The differences here noted vary according to the source and methods of manufacture :—

Material.	Tan % (official method).	Tan % (Bennett).	Difference.
	%	%	%
1 Sumach	24·5	23·0	1·5

THE ANALYSIS OF TANNING MATERIALS.

Part II.—Tannery Liquors.

BY HUGH GARNER BENNETT, M.SC.

The results of the analysis of used tan liquors, when obtained by the official method of the International Association of Leather Trades' Chemists for tanning materials, are far from trustworthy. The author has given considerable attention to this question, which has been much neglected in the past.

It has been found a great advantage to utilise the improved basic chloride method suggested in the preceding paper. The gain in accuracy is even greater with liquors than with tanning materials, on account of the relatively higher non-tannin content of the former. In reducing the proportion of hide powder employed and in working at a greater dilution, the improvement in accuracy is considerable. In the matter of the acidity of the hide powder, due either to its original acidity or to the chroming, the arguments have even greater force for liquors than for materials, because liquors are always so acid themselves that any acidification of hide powder is superfluous. The only point of chroming is to render the powder insoluble.

However the I.A.L.T.C. regard the improved method with respect to tanning materials, there can be no arguments of financial interest against the immediate adoption of these improvements for tannery liquors.

In the ordinary analysis of yard liquors the determination of insoluble matter is usually not required. The most convenient plan, therefore, is to filter the liquor through filter paper before dilution. If it is required to determine the insoluble matters, special care must be taken in sampling, as the distribution of the mud in a pit of liquor varies enormously. It is incorrect, moreover, to dilute the liquor and then filter it, for what is required is the amount of insoluble matter in the liquor itself, not in the liquor if it were diluted. For the "total solids," the same volume of liquor as is taken for the "solubles" and "non-tannins" should be diluted into another flask.

In the tannery, results stated in percentage by volume are of far more value than those in percentage by weight. Hence the amounts of liquor taken for dilution should be measured. The "barkometer strength" of the liquor is usually noted before analysis so that by the specific gravity it is always possible to calculate the results into percentage by weight. For the weaker liquors there is no advantage in accuracy in making one litre of diluted liquor, and there is much gain in convenience and speed by making up only half a litre, and for the weakest liquors only a quarter of a litre. Sometimes, indeed, no dilution at all is necessary. Pipettes are the best means of measuring the liquors and it is very convenient to have a set of pipettes delivering 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 75, 100, 150 and 200 c.c. respectively. The liquors are delivered into the dilution flasks containing cold distilled water and made up to mark with cold distilled water. Hot water is unnecessary as the liquor is clear and dissolves without difficulty. In the case of strong liquors odd quantities are necessary, and a 10 c.c. graduated pipette is useful in addition to those mentioned above.

As the detannisation is to be carried out at a dilution of 0·2% tannin approximately it is best to dilute to this strength direct and use this solution both for the determination of the "soluble solids" and of the "non-tans."

This halving of the usual quantities involves no loss of accuracy in weighing for the residues from 50 c.c. of a 0·2% tan solution of even the newest liquors of a tanyard is greater than that obtained from the "non-tannins," of some quebrachos. In the case of the older liquors this extra dilution is a great advantage as the amount of solid matter in a 0·2% tan solution increases rapidly as the liquors become older.

It is convenient also to use the same bottles, churn, and other apparatus as in the I.A.L.T.C. method, so that 100 c.c. of the liquor is employed, and to detannise this only 2½ grms. dry hide powder will be required. This will weigh 7—9 grms. when washed and pressed, so that the 100 c.c. are conveniently made into 110 c.c. by the addition of distilled water. To avoid a factor it is convenient to evaporate 55 c.c. of the non-tan filtrate, which is equivalent to 50 c.c. of the original liquor solution. Duplicate analyses, such as are usual in extract analysis, are unnecessary for liquors so that it is possible for one operator to undertake more than twice as many liquors as extracts.

Even with the improvements suggested the gravimetric method is still open to grave criticism when applied to old tan liquors which have been worked down the yard in the usual way. If solutions containing 0·2% tannin are used and 50 c.c. evaporated for "soluble solids," the results are still unreliable, for it is impossible to get constant weight. Basins and residues lose from 10—30 mgms. at each re-weighing and the residue obviously decomposes, becoming quite black. Results in soluble solids may vary over a range of 1½%, which is absurd when one is attempting to estimate ½ to 1% of tan. The same inconstancy is observed in weighing the non-tannin residue, rendering the tannin result doubly uncertain. The reasons for this difficulty are not far to seek. There is too much residue to dry effectively in the ordinary way. Well over 1 gram of residue is sometimes obtained from 50 c.c. of solution even when diluted to the extent suggested above, and it is quite impossible to dry a layer of this on the bottom of even a flat-bottomed basin. The best and simplest plan is to evaporate a smaller quantity than the usual 50 c.c. For nearly spent liquors 20 c.c. and 10 c.c. are convenient alternatives. The gain in accuracy in this respect involves a further gain also, because the evaporation taxes only a very short time comparatively and thereby eliminates the possibility of much decomposition in the heated liquor. There is also a considerable gain in speed. The author recommends as a general rule that the residues to be weighed should never exceed 0·25 gram. Whatever volume is employed for the total solids, should, for the same reasons and for convenience in calculation, be employed also for the non-tannins.

Loss of weight on drying is also connected with the chemical action of the constituents of the residue. Experiments made by the author in conjunction with Dr. J. G. Parker some years ago (this J., 1908, 1193) showed that it is impossible to evaporate mixtures of tannin and calcium acetate and obtain the theoretical results. The tannin not only expels the acetic acid, but the calcium tannate rapidly oxidises. It may be suggested that in liquors there is excess of various acids; this is not always the case, especially in the first liquors of a yard, which often receive a great amount of lime in the course of a day's work. Furthermore, if the liquor is acid, the excess of volatile acids is driven off in evaporation, and the non-volatile acids—such as gallic acid—are just as susceptible as the tannin to similar oxidation. A simple remedy for this difficulty is to acidify the liquors (soluble solids and non-tannins) just before evaporation (not before analysis) with tartaric acid, of which 5 c.c. of a ½% solution is employed. This acid assists materially in the complete expulsion of the volatile acids, both free and combined. It also keeps the liquor always acid and so prevents the alkaline oxidation due to lime salts with weak acids. Similarly it ensures an acid residue and so prevents the oxidation of any tannate of lime. Tartaric acid is non-volatile, and the weight used, 25 mgrms., can be deducted from the weight of the residue. The difference in colour in residues evaporated with and without the acid is very noticeable. Oxalic acid seemed at first more suitable than tartaric acid for this purpose on account of its calcium salt being insoluble even in acid solution, but with oxalic acid, however, it is impossible to obtain a residue of constant weight. Tartaric acid, on the other hand, does not decompose at 100° C., has no water of crystallisation, and gives a crystalline residue of constant weight after half an hour's drying at 100° C.

Apart from the lime and other alkali salts present in tan liquors, there is probably a greater tendency to oxidation in liquor residues than in those from fresh materials, and there is therefore a strong objection to heating at 100° C. for any great length of time. The presence of tartaric acid is again of some value, for it is also a mild reducing agent and would tend to retard any such oxidation of the tannin and non-tannin residues. The author has found it a great advantage to concordance of results to limit to a definite extent the time which shall be allowed for drying residues, and has made a practice of giving one hour's drying exactly and no more. Whilst this is an advantage to concordance it is in all probability an advantage also in correctness of result, for after one hour at 100° C. the error due to water is of far less importance than the error due to decomposition and oxidation. This desirability for limited time in drying justifies also the employment of small residues.

The author therefore recommends that the analysis of tannery liquors should be carried out as follows:—

The liquor is passed through filter paper until clear. A solution of the filtered liquor is made to contain between 0·17 and 0·23% tannin. The volume of clear liquor necessary for this is pipetted into a litre, half-litre, or quarter-litre graduated flask containing some distilled water. The flask is filled up to the mark with distilled water and mixed well.

To determine the *total soluble matters*, 50 c.c. or less of this solution should be evaporated to dryness in flat-bottomed basins, into which 5 c.c. of a ½% solution of tartaric acid has previously been pipetted. The weight of residue so obtained must not exceed 0·25 gram. When the solution is evaporated to dryness, the basin is dried in a steam oven for one hour only, and then cooled and weighed. From the weight of the residue 25 milligrams must be deducted before the percentage is calculated.

To determine the *non-tannin matters* the procedure is as follows:—The moisture of the air-dry hide powder is determined and the quantity equal to 2½ grams actual dry hide powder is calculated. Any multiple of this quantity is taken, according to the number of analyses to be made, and wet back with 10—12 times its weight of distilled water. The acidity of the hide powder is determined in the usual manner, and the volume of $N/10$ caustic soda necessary exactly to neutralise 2½ grams of dry hide powder is calculated. Any multiple of this quantity, according to the number of analyses being made, is added to the wet hide powder and well mixed until the mass gives no pink colour when one drop of a 0·1% alcoholic solution of phenolphthalein is added. The chroming solution is then added.

For chroming, 2% of chromic chloride ($Cr_2Cl_6 12H_2O$) on the weight of the dry hide powder is employed, its solution being made basic to correspond to the formula $Cr_2Cl_2(OH)_4$ by the addition of sodium carbonate. A 10% stock solution of this chroming liquor is very convenient and is made by dissolving 100 grams of the chromic chloride crystals in a little distilled water in a litre flask and very slowly adding a solution 40 grams of anhydrous sodium carbonate, with constant stirring, finally making up to mark with distilled water and well mixing. Of this solution ½ c.c. should be used for 2½ grams dry hide powder, *i.e.*, for each analysis.

The hide powder and chrome solution are churned slowly for one hour, and the powder is then washed free from chlorides and soluble matter, as in the Procter-Bennett shake method. The silver nitrate test should be similarly employed. The hide powder is then squeezed to contain about 70% of water and the whole weighed. The amount M, containing 2·5 grams dry hide powder is thus found, weighed out, and added immediately to 100 c.c. of the diluted solution of the liquor, along with (12·5—M) c.c. of distilled water. The whole is corked up and agitated in a rotating churn for 15 minutes, and then squeezed immediately through linen. The liquor obtained is again filtered through filter paper, the filtrate is returned till clear, and 55 c.c. or less (according to the amount used for the total solids) is evaporated to dryness in flat-bottomed basins into which 5 c.c. of a ½% solution of tartaric acid has been previously pipetted. When the solution is evaporated the basin should be dried at 100° C. for one hour, cooled, and weighed. From the weight of the residue 25 milligrams must be deducted before calculation.

If the official hide powder is to be employed, the quantities to take for batch B1 are given in the following table:—

No. of liquors to be analysed.	Weight of official hide powder to take.	No. of c.c. $N/10$ NaOH required.	No. of c.c. $Cr_2Cl_2(OH)_4$ solution required.
	%	%	%
1	2·85	1·4	0·5
2	5·70	2·8	1·0
3	8·55	4·2	1·5
4	11·40	5·6	2·0
5	14·25	7·0	2·5
6	17·10	8·4	3·0
7	19·95	9·8	3·5
8	22·80	11·2	4·0
9	25·65	12·6	4·5
10	28·50	14·0	5·0
11	31·35	15·4	5·5
12	34·20	16·8	6·0

The advantages claimed for this method of analysis over the I.A.L.T.C. method are—

(1) A considerable improvement both in accuracy and in concordance. This applies to the estimation of soluble solids, and of non-tannins also. The method shows distinctly less tannin than the official method.

(2) A much greater ease of execution. Both in washing the hide powder and in weighing the basins, 5 tan liquors involve less work than 1 extract done in duplicate.

(3) A considerable saving in cost. As only 2½ grams of hide powder are used per analysis, the cost is little more than ⅕ that of the official method.

NOTE ON THE TANNINS OF VALONIA, OAKWOOD, AND CHESTNUTWOOD.

BY HUGH GARNER BENNETT, M.SC.

For some time the author has been engaged in an investigation for distinguishing better the various tanning materials, more especially those of the "pyrogallol group." The various tests suggested have each been confirmatory of the classification first proposed, viz., that valonia, oakwood, and chestnut tannins form one closely allied section, whilst sumac, myrabolans, and algarobilla fall into another section together. This arrangement is suggested by the following tests previously devised by the author, viz., the chromate test, the iodine test, the aqueous ferricyanide test, the ammoniacal ferricyanide test and the ammonium cobaltate test. This arrangement is also in harmony with other tests devised by Procter and other workers, viz., the lime water test, the sodium sulphite test, the copper sulphate and ammonia test, the lead acetate test, and the lead acetate and acetic acid test.

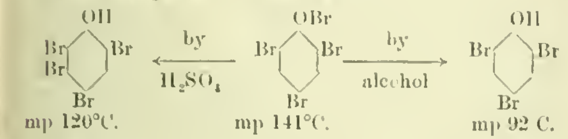
These two sections are now fairly sharply marked and can easily be distinguished. There remains the important problem of distinguishing the different individual members of each section. To solve this in connection with the valonia section is the object of this investigation. So far as the author is aware, the behaviour of valonia, oakwood, and chestnut tannins is practically the same towards every known test. The only slight differences are:—(1) In the lead acetate and acetic acid test, the precipitation of the tannin is complete with valonia and oakwood and *almost* complete with chestnut. (The sumac section and mixed tannins give partial precipitation and catechol tans no precipitation.) (2) In the formaldehyde test valonia gives a slight turbidity, whilst the other two remain clear.

These differences are too slight to be of great practical value, and it is clear that some new methods must be devised. That there is actually a difference between these three materials is evident from the fact that valonia makes a different leather from chestnut, whilst oakwood may be considered to be intermediate between valonia and chestnut in its practical effect.

The author has found that it is possible to distinguish these three materials easily by the action of bromine water upon a solution of the products obtained when solid extracts of these materials are subjected to dry distillation. The extracts are evaporated to dryness on the steam bath, powdered, and dried further at about 30° C. if convenient. For the dry distillation an inexpensive retort is easily made from a piece of tubing about 6 inches long and rather over ½ inch in internal diameter, closed at one end, which receives a layer of the dried extract. The open end of the tube is fitted with a cork through which passes a delivery tube leading into a test-tube acting as the receiver. This delivery tube acts as an air condenser. It is best to keep the wide tube horizontal and to bend the delivery tube at right angles. The extract is gradually heated until blackened and is then strongly heated till no more distillate is received. This only takes 5—10 minutes. The distillate is shaken with 10—15 c.c. distilled water and filtered from the tarry matters which remain undissolved. An excess of fairly strong bromine water is added to the filtrate and the mixture is shaken up well.

Under this treatment valonia yields a dense yellow crystalline precipitate, which after filtering, washing with cold water and drying, appears under the microscope as a mass of yellow plates. This precipitate has been found to be tetrabromophenol ($C_6H_2Br_3.OBr$) and exhibits the following properties:—It is insoluble in water and cold alcohol, and is best purified by washing with these reagents successively. The melting point of the crude substance varies according to the conditions of precipitation, but is generally between 120° C. and 136° C. After purification by washing repeatedly with cold alcohol it melts fairly sharply at 139°—141° C. with decomposition, bromine being evolved. Watts' "Dictionary of Chemistry" gives the m. pt. of these substances as 118° C., which led the author to think at first that the product he had obtained was an impure tribromophloroglucinol, $C_6Br_3(OH)_3$, m. pt. 151°. An experiment with pure phenol, however, showed that the 118° C. was an error, and that tetrabromphenol, $C_6H_2Br_3(OBr)$, melts at 139°—141° C. like the product obtained from valonia. This product liberates iodine from potassium iodide, a reaction which appears typical of compounds containing the radicle—OBr. It cannot be recrystallised from alcohol, as hot alcohol decomposes it fairly easily, yielding tribromphenol, $C_6H_2Br_3(OH)$. From very dilute alcohol this may be crystallised easily, yielding a felted mass of white needles, which after repeated recrystallisation from dilute alcohol, give a melting point of 92° C. The product is also acted upon by warm sulphuric acid, undergoing intra-molecular change into its isomer tetrabromphenol, $C_6HBr_4(OH)$, which on recrystallisation from dilute alcohol yields white needles with a m. pt. of 120° C.

These changes are indicated thus :—



Under similar treatment the tannin of chestnut yields no precipitate with bromine water and hence none of the above products. The two materials are thus very easily distinguished, and there seems little doubt that this difference involves a radical difference in the constitution of the respective tannin molecules. It is clear also that it would be an easy matter to detect the presence of valonia tannin in mixture with chestnut or any other tannin which under this treatment yields no precipitate with bromine water.

Under this treatment the tannin of oakwood yields a distinct turbidity with bromine water, but in the author's first experiments he failed to filter this precipitate for purposes of investigation. Repeated attempts, however, and larger quantities yielded a small quantity of a dark product melting at 107°—112° C. This dissolves in hot alcohol, which upon dilution and cooling yielded white felted needles, m. pt. 86°—89° C. There can be little doubt that these are the same products (only impure) as were obtained in the case of valonia, but the quantities obtained were so exceedingly small that further purification and investigation were impossible. This indicates that oakwood also contains at any rate a small quantity of that tannin which yields phenol on dry distillation. This behaviour justifies the statement made above that the practical effects of oakwood are between those of valonia and chestnut.

Under a similar treatment myrobalans behaves like chestnut, and yields no precipitate with bromine water. This gives some chemical justification to the tanner, who, when he desires to substitute "extract" in his tannage for "dry material," uses oakwood to replace valonia, and chestnut to replace myrobalans.

This distillation process has been repeated a good many times with each of the materials mentioned, and that there is little doubt that the result is the characteristic behaviour of each of the materials in question. The results, moreover, are somewhat encouraging to the view that in this way it is possible not only to differentiate the different tannins, but also to throw some light upon their chemical constitution. The work is being continued with the tannins of other groups, upon which it is hoped to report later. The results, so far, indicate that the other members of the pyrogallol group of tannins (myrobalans, gallotannic acid, etc.) yield no precipitate with bromine water; whereas the catechol tannins (quebracho, gambier, mimosa bark, etc.) yield a precipitate which is *not* tetrabromphenol, but a sticky, tarry product which the author has failed to crystallise or purify.

Another line upon which it is hoped to obtain fruitful results is to apply other reactions to the products of dry distillation. The distillates from valonia, oakwood and chestnut, for example, give a precipitate with lead acetate, which may be due either to pyrogallol or catechol. They also give *feebly* the potassium cyanide reaction and the iodine reaction for pyrogallol. As these last are very delicate reactions there seems no doubt that pyrogallol is a minor product in the distillation, and it becomes a question whether valonia, oakwood, and chestnut can really be regarded as pyrogallol tannins, for neither their infusions nor their dry distillates give the reactions which are peculiar to the pyrogallol grouping. The exception is the purple colour obtained with copper sulphate and ammonia precipitate. This is given by pyrogallol itself but is not given by the other pyrogallol tannins. The alternative conclusion, therefore—which is perhaps more probable—is that these three tannins are actually pyrogallol derivatives but that the pyrogallol grouping has a different place in the molecule, or a different relation to the rest of the molecule, than is the case with the other pyrogallol tannins.

Lectures.

ORGANIC ARSENIC COMPOUNDS.

A Chapter in Applied Chemistry. A. A. Boon. Inaugural Sessional Address delivered before the North British Branch of the Pharmaceutical Society, on Nov. 27, 1914. Pharm. J., 1914, 93, 836—838. (See also Martindale, this J., 1909, 907—911.)

For some months now our attention has been called to the shortage of dyestuffs, and we were lately informed of the efforts which are being made to meet and overcome this difficulty. When we recall the fact that the manufacture of synthetic drugs is the latest development of the coal-tar colour industry, I need hardly say that pharmacists ought to be interested in any steps that are being taken to put the colour industry on a firm basis in Britain, for progress in the one branch of applied chemistry means progress in the other.

One of the most recent chapters dealing with synthetic drugs is that relating to organic compounds containing arsenic and antimony. I propose now to give a very brief account of the chemistry of some of these so-called arsenicals. Apart from their chemical interest, some of them, as you know, are regarded as chemical specifics in diseases due to protozoa.

The problem relating to the nature of the liquid which is obtained when a mixture of white arsenic and potassium acetate is distilled was undertaken in the early part of the last century. As a matter of fact, that investigation led to the discovery of cacodyl and its derivatives, which thus became the first examples of compounds in the aliphatic series of hydrocarbons containing arsenic.

The physiological action also of these aliphatic arsenicals was undertaken by their discoverer. It was found that although cacodyl and its oxide were very poisonous, yet cacodylic acid, which contains 54 per cent. of soluble arsenic, was practically harmless. It is interesting in this connection to note that in cacodylic acid the arsenic is pentavalent, and in the other derivatives just mentioned the arsenic is trivalent.

As a sodium salt cacodylic acid has been used in medicine, but at present the *aromatic* compounds containing arsenic have practically displaced the *aliphatic* arsenicals.

Two general methods are employed for preparing the aromatic compounds containing arsenic. One is effected by the action of arsenious chloride on mercury diaryl derivatives—products which result from the interaction of sodium amalgam and the bromo-derivatives of the aromatic hydrocarbons; and the other is accomplished by the addition of sodium to an ethereal solution of arsenious chloride on chlorobenzene and analogous aryl halides. By means of these two methods primary, secondary, and tertiary aryl arsenicals and their derivatives have been prepared. From one of these derivatives, viz., *phenyl arsenious oxide*, *arsenobenzene* can be obtained by the reduction of the oxide with phosphorous acid, this being carried out in alcoholic solution. *Arsenobenzene*, which crystallises in yellow needles, is theoretically very important. It is the parent substance of "Salvarsan," and is really the analogue of *azobenzene*, the mother substance of the azo-dyes.

For the manufacture of magenta from aniline containing o- and p- toluidines arsenic acid has been now employed for a number of years as an oxidising agent. This use of arsenic acid was the outcome of a study of the action of various oxidising agents on aniline and its homologues after the discovery of mauve (the first so-called "aniline dye") about the middle of last century.

In 1863 it was shown that arsenic acid had another action on aniline, for when aniline arsenate was heated (190°—200° C.) one of the products was a colourless compound, which was regarded by its discoverer as an anilide of arsenic acid. A number of salts of this compound were also described, and amongst them was the sodium salt. The constitutional formula assigned to the anilide referred to is given below (I.). The sodium salt derived from it was introduced into therapeutics under the commercial name of "atoxyl," and to it was ascribed the structural formula II. These formulæ, however, proved to be erroneous, for in 1907 it was shown that the action of arsenic acid on aniline was exactly comparable with that of sulphuric acid on this aryl-amine. The product obtained from the latter reaction is usually known as sulphanilic acid (III.), and so by analogy that resulting from the former was called arsanilic acid (IV.).

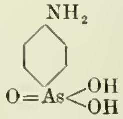
III.



IV.

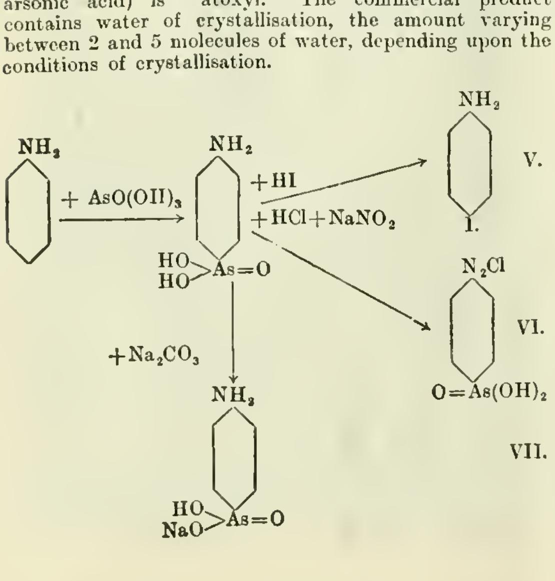
That arsanilic acid had the above constitution was proved by the following experimental facts :—

(1) It could not be decomposed into arsenic acid and aniline by any of the ordinary reagents which are used to hydrolyse anilides.

(2) By boiling it with hydriodic acid, p-iodoaniline (V.) was obtained, thus indicating that the "arsonic" group (the arsenic atom in the nucleus) was in the para-position with respect to the amino group.

(3) It could be diazotised (VI.), thus showing the presence of a free amino group.

The sodium salt of arsanilic acid (or para-amino-phenyl-arsonic acid) is "atoxyl." The commercial product contains water of crystallisation, the amount varying between 2 and 5 molecules of water, depending upon the conditions of crystallisation.



V.

VI.

VII.

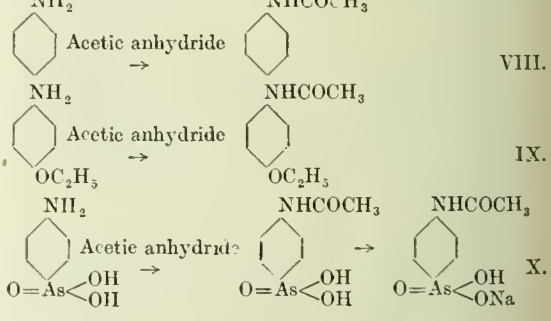
"Atoxyl" (VII.) is prepared by heating arsenic acid with excess of aniline (180°—190° C.), then extracting with sodium carbonate, and re-crystallising from water. The pure salt, which contains 5 molecules of water, is known commercially as "Soamin."

These colourless sodium salts have been used in the treatment of sleeping sickness, syphilis, and other diseases of protozoal origin, but on account of their unpleasant or dangerous by-effects they must be employed with caution.

The elucidation of the constitution of "atoxyl" was followed by the synthetical preparation of *aromatic* compounds containing arsenic with a view of obtaining a series of compounds of lower toxicity to the host and of a higher toxicity to the parasites. At first compounds containing *pentad* arsenic were prepared, but more recently attention has been directed to the syntheses of those containing *trivalent* arsenic, for experiments proved that the latter were, from the pharmacological point of view, of more value than the former. It would obviously be impossible to treat such a series in a systematic way. I will therefore select just a few of the interesting bodies, the production of which depends on reactions familiar either in the study of synthetic drugs or dyestuffs.

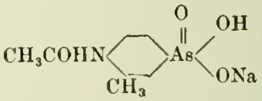
It was already known that such toxic compounds as aniline and phenetidine could be rendered less toxic by introducing an acetyl group into either of them. As a result we have now the well-known drugs, acetanilide, from aniline (VIII.), and phenacetin, from phenetidine (IX.).

Accordingly arsanilic acid was subjected to the process of acetylation by treating with acetic anhydride. An acid was thus obtained, the sodium salt of which constitutes the "arsacetin" (X.) of commerce. This drug, as was expected, was less toxic than atoxyl; being chemically more stable, its solutions can be sterilised by boiling.

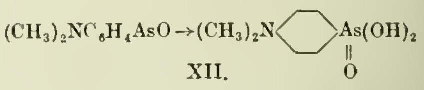


Substances which were exactly analogous to those derived from aniline were prepared from o-toluidine as a starting-point. One of these, commercially known as "Orsudan" (XI.), is the o-tolyl analogue of "arsacetin," and resembles that compound in its therapeutic action.

Alkyl derivatives of atoxyl were also investigated. One of these, dimethylarsenilic acid (XII.) is produced by oxidising dimethylaniline arsenious oxide either with mercuric oxide or alkaline permanganate. These various alkyl derivatives have, however, proved to be of no value therapeutically.



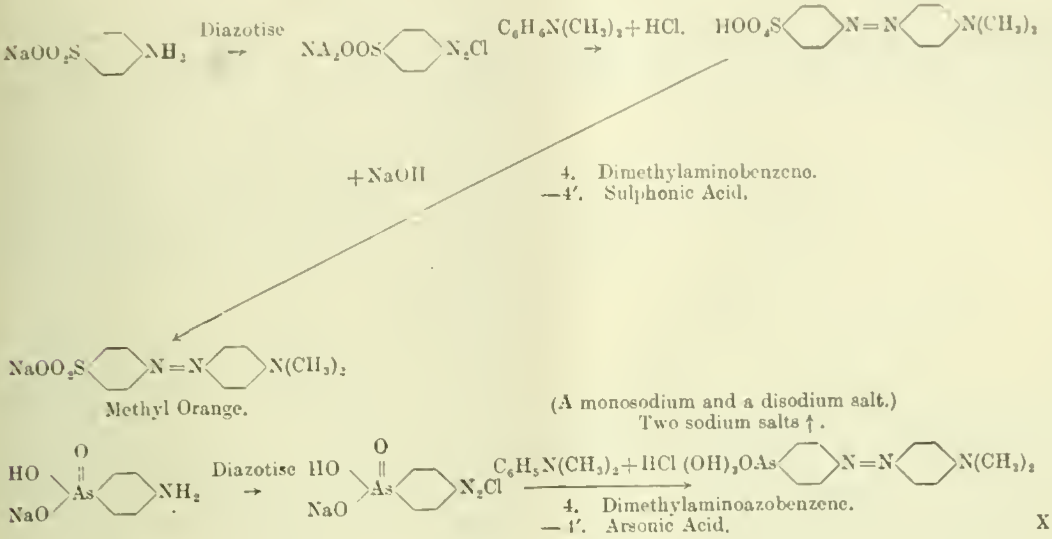
XI.



XII.

Atoxyl and its homologues can be converted through the diazo-reaction into compounds comparable with the azo-dyestuffs. These latter, which include a very large number of dyestuffs, are in general prepared by diazotising an amine and "coupling" with a phenol or an aromatic amine. The reactions concerned in the preparation of Methyl

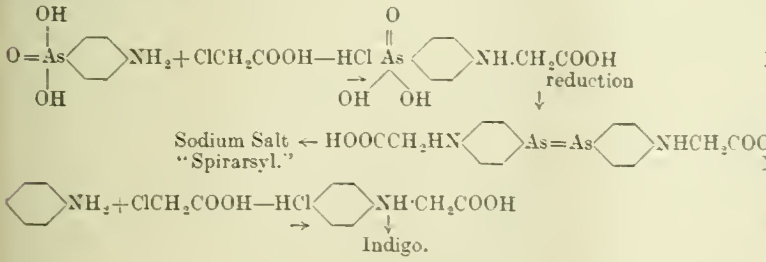
Orange and those of the analogous compound containing arsenic may be represented by the following schemes :—



XIII.

Two sodium salts of the arsenical compound (XIII.) have been prepared, a mono-sodium and a di-sodium salt. Both of these are scarlet compounds. Various similar arsenical compounds have been examined, but as a class they are only of chemical interest.

The several derivatives of "atoxyl" to which I have just called your attention contain arsenic in the *pentavalent* condition. I must now refer to the more important compounds in which arsenic possesses triad functions. In the investigation of aryl arsenicals containing pentavalent arsenic, a derivative of arsenilic acid was discovered, viz., phenylglycine para-arsonic acid, which may be obtained by the interaction of chloracetic acid and arsanilic acid (XIV.). This reaction reminds one of the first step in the commercial synthesis of indigo starting with aniline as raw material. For this purpose the base is condensed with chloracetic acid, and the resulting phenylglycine (XV.) is subsequently converted into indigo. In practice phenylglycine para-arsonic acid is prepared by mixing solutions of atoxyl with chloracetic acid in hot aqueous solution. Phenylglycine para-arsonic acid is important, for on reduction with sodium hydrosulphite, caustic soda and magnesium chloride, it yields arsenophenylglycine (XVI.), which is a reddish brown powder, soluble in sodium carbonate solution. The sodium salt thus obtained is known as the drug "Spirarsyl" ("418"). It is less toxic than atoxyl, and has been used in syphilis with favourable results. Its administration is said to have no harmful by-effects.

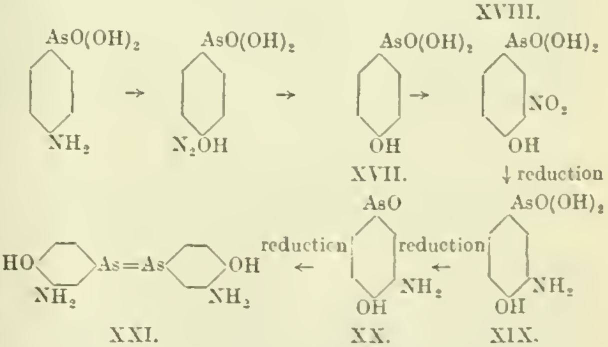


XIV.

XVI.

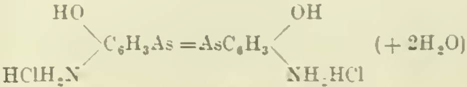
XV.

By means of the diazo reaction arsanilic acid can be converted into p-hydroxyphenylarsonic (XVII.) acid. This compound was obtained shortly after the study of the aryl arsenicals was begun. It could also be prepared by the action of phenol on arsenic acid (at 150° C.). In practice the first method consists in boiling a solution of atoxyl, after diazotising, and separating the compound from the sodium chloride formed in the reaction by means of acetone. Parahydroxyphenylarsonic acid is not used therapeutically, but through it some important derivatives can be secured, amongst them "Salvarsan." The following steps indicate the process of preparing Salvarsan from p-hydroxyphenylarsonic acid. The latter compound is first nitrated, whereby a nitro derivative is obtained, the nitro group entering the ortho position to the hydroxyl group, or the meta position with respect to the arsonic group. The resulting nitro compound (XVIII.) is then reduced (XIX.-XXI.).



The last product in the reduction XXII. is 4 : 4'-dihydroxy-3 : 3'-diaminoarsenobenzene. The dihydrochloride of this compound constitutes the drug "Salvarsan" (XXII.).

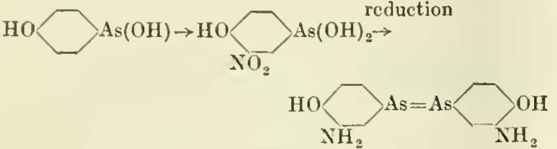
Salvarsan is used as a specific for syphilis. It is a bright yellow powder, kept in contact with an indifferent gas so as to prevent the compound from oxidising.



$\mathrm{(HO)(HClH_2N)C_6H_3As=AsC_6H_3(OH)(NH_2.HCl)\ (+2H_2O)}$

XXII.

The hydrosulphites, which are employed in operations connected with the dyeing industry as reducing agents, are also useful in the preparation of arsenicals. Mention has already been made of sodium hydrosulphite in connection with "Spirarsyl;" the same salt has been employed in the preparation of Salvarsan. Thus, after nitrating p-hydroxyphenyl-arsonic acid, mentioned above, the resulting nitro-derivatives can be reduced with sodium hydrosulphite in presence of caustic soda and magnesium chloride (XXIII.).



XXIII.

XXIV.

Further, by means of the hydrosulphite formaldehyde-sulphoxalate "Salvarsan" itself has been reduced with the production of an acidic compound, which, when neutralised with soda, forms a sodium salt, known as the drug Neosalvarsan (XXIV.). Neosalvarsan dissolves in water to a neutral solution, and has decided advantages over solutions of Salvarsan, for the latter are not only easily oxidised, but are also acidic, and this acidity has to be neutralised before the drug can be administered intravenously.

From this brief sketch you would have noticed how in the application of chemical science to the production of aniline dyes there has been opened up a series of new and highly potent arsenical compounds possessing remarkable therapeutic value. They are applied by a method of treatment termed chemotherapy, the principle of which is to employ chemical substances in infectious diseases which hinder the development of the parasites giving rise to such diseases without being harmful to the patient —at least, in doses required to destroy the parasites. The organic chemical compounds thus obtained are called parasitotropic chemicals. Further investigations, which are at present being undertaken in connection with these arsenicals, have for their object not only the discovery of synthetical methods for the preparation of new drugs, which may prove more potent than those which have already been found to be therapeutically useful, but also the improvements of the methods which are employed in the production of the latter.

THE RESULTS OF THE STUDY OF COLLOIDS.

T. Svedberg. Delivered before the German Chemical Society, Nov. 29, 1913. Ber., 1914, **47**, 12—38. [Abstract.]

The term colloid was used by Graham to denote a class of substances possessing a very small power of diffusion; and in cases where a substance was found capable of existing both as a colloid and as a crystalloid, the two forms were regarded by him and his successors as allotropic modifications. This view was, however, gradually displaced and more recently it has been recognised that the distinctive properties of colloids are due, not to their intramolecular, but to their extramolecular or physical structure. The truth of the latter view was conclusively established in 1903, when examination of colloidal solutions with the ultramicroscope of Siedentopf and Zsigmondy (compare Michaelis, this J., 1906, 715) showed that they are heterogeneous. Colloidal solutions may hence be defined as systems composed of minute particles suspended in a gaseous, liquid, or solid medium. In accordance with a proposal of Wo. Ostwald in 1907, the total mass of the suspended particles is frequently designated the disperse phase, whilst the other component (the continuous phase), is termed the dispersion medium. Following Graham, colloidal solutions are also termed sols, *e.g.*, hydrosols with water as dispersion medium, alcohols with alcohol, and so on. In the ultramicroscope an intense beam of light is directed through the solution and the illuminated field is viewed through a microscope in such a way that only that portion of the light which is refracted by the suspended particles, and which is linearly polarised, is observed. The suspended particles appear as bright points of light, and by counting the number in a known volume of the liquid and dividing by the total mass of the disperse phase in the same volume, the mass of a single particle can be calculated, and from this, assuming the particles to be spherical or cubical, the size of the particle. The smallest particles hitherto definitely detected in this way are metallic particles of the order of 5-millionths of a millimetre ($5\mu\mu$). Another method used in investigating the structure of colloidal solutions, is that of ultra-filtration, devised by Bechhold (this J., 1906, 1177; 1907, 993), the solution being filtered under pressure through paper impregnated with collodion or gelatin solutions of different concentrations. By suitable choice of filters, colloids having particles of different sizes can be separated one from another.

Substances in colloidal solution can be precipitated in various ways, the process being termed coagulation, and the separated substance, the coagulum; or, following Graham, a gel. Until about 2 years ago, gels were mostly regarded as having a fine network structure (Bütschli, 1892—1898) or consisting of very small or invisible "foam cells" with liquid or solid "foam walls" (Quincke, 1901). More recently the work of Zsigmondy and his pupils (this J., 1911, 1056; 1912, 82, 1084) has shown that gels have a minute granular rather than a foam-like structure, and Odén (this J., 1912, 260) has shown that in the case of reversible gels, the particles in the original colloidal solution and in the solution regenerated from the gel are of the same order of size, whence it may be inferred that the particles retain their individual character during coagulation. It has been shown by Zsigmondy (this J., 1911, 1056; see also Anderson, this J., 1914, 829) that the phenomena observed in the dehydration and rehydration of gels can be satisfactorily explained by the extreme fineness of their structure, and he has calculated that the size of the hollow spaces in silicic acid gel is of the order of $5\mu\mu$.

Any process leading to the formation of minute particles may serve as a method of preparing colloids, the chief requirement being that the particles must be practically insoluble in the surrounding medium. For example, in the case of $BaSO_4$, AgCl, AgBr, AgI, the ease of formation of aqueous colloidal solutions increases in the order given, the respective solubilities being $2 \cdot 10^{-4}$, $1 \cdot 10^{-4}$, $1 \cdot 10^{-5}$, and $1 \cdot 10^{-7}$%. Stable colloidal solutions of sodium chloride in benzene, in which its solubility is very small, can be obtained (Paal, this J., 1906, 1066). In many cases stable colloidal solutions can only be obtained if traces of electrolytes are present; and frequently, also, coagulated colloids can be again brought into colloidal solution, or peptised, by addition of traces of electrolytes. Most methods for the formation of colloidal solutions depend upon the condensation of molecules to larger aggregates (colloidal particles), as, for example, in the formation of colloidal metals by reduction, of metallic hydroxides by hydrolysis, etc. In other methods, compact material is disintegrated either electrically or mechanically. Von Weimarn has prepared colloidal solutions by finely pulverising an insoluble substance with an inert soluble substance, such as urea, and dissolving the mixture in water. Electrical disintegration methods are widely used (Bredig, this J., 1899, 50, 281; Svedberg, this J., 1906, 543). In some cases colloidal solutions are formed merely by irradiation of compact metal immersed in a liquid (*e.g.*, silver in water or alcohol) with ultra-violet light. According to unpublished experiments of Nordenson, this is not due to direct disintegration of the metal by the action of the light, but is a purely photochemical process, the metal dissolving in the liquid as a crystalloid and being subsequently reduced with formation of colloidal particles. Traube-Mengarini's statement (this J., 1910, 700; 1911, 219) that compact metals may dissolve directly to colloidal solutions in distilled water is incorrect: the phenomena observed are due to chemical reactions and do not occur—at any rate in the case of silver, gold, and platinum—if the water be sufficiently pure and light be excluded.

The most important method of purifying colloidal solutions is by dialysis, the technique of which has been greatly improved by Zsigmondy (this J., 1910, 1249). Another method consists in the coagulation and re-solution of the colloid, but is only applicable in special cases.

Zsigmondy (Z. physik. Chem., 1906, **56,** 65) first prepared colloidal solutions with particles of approximately uniform size, by adding a previously prepared colloidal gold solution to a mixture of a gold solution and a reducing agent: the reduced gold was deposited entirely on the ready-formed colloidal particles and by varying the conditions, sols with particles of different but approximately uniform size were obtained. Other methods of preparing such solutions are by fractional centrifuging (Perrin, Kolloidchem. Beihefte, 1910, **1,** 242), ultra-filtration (Bechhold, *loc. cit.*), and fractional coagulation (Odén, *loc. cit.*).

It was considered formerly that a clear distinction could be drawn between colloidal and true solutions by reason of the former possessing very small osmotic pressures. Einstein has pointed out, however, that the concentration of colloidal solutions varies not according to the weight of the disperse phase but according to the number of particles therein, a $N/1$ colloidal solution being one in which the number of suspended particles per litre is the same as the number of molecules in a $N/1$ true solution or in 2 grms. of hydrogen, viz., $6{\cdot}10.10^{23}$; and a considerable amount of experimental evidence has been accumulated from diffusion experiments and study of the Brownian motion, showing that if the osmotic equivalence of molecules and suspended particles be accepted, van't Hoff's formula for expressing the osmotic pressure may be applied to dilute colloidal solutions.

The suspended particles of a colloidal solution frequently carry an electric charge and such solutions hence possess greater electrical conductivity than the dispersion medium (intermicellar liquid). Under the influence of a difference of potential the charged particles travel in a similar manner to ions. The velocity of migration of the particles is of the same order as that of ions, and in many cases is strongly affected by addition of electrolytes. By the aid of Stokes' resistance-formula, Zsigmondy has calculated that in the case of a silver sol having particles of $50\mu\mu$ diam. and a mobility of 2μ, the charge on each particle is 297.10^{-10} electrostatic units, which is about the same as that which would be carried by an ion having a valency of 62. With increasing concentration, above a certain limit the electrical conductivity of colloidal solutions also increases and more rapidly, colloidal solutions differing in this respect from true solutions.

As the sum of the limiting surfaces between the suspended particles and the dispersion medium in colloidal solutions is very large, adsorption phenomena play a great part, and it has been shown independently by Ostwald (van Bemmelen-Festschrift, 1910, 267) and by Lottermoser and Maffia (Ber., 1910, **43,** 3613) that an adsorption-equilibrium exists in colloidal solutions. Hardy (J. of Physiol., 1899, **24,** 288) found that in many colloidal solutions spontaneous coagulation occurred when the electric charge carried by the suspended particles was neutralised in any way; and most colloidal solutions are considerably less stable at the isoelectric point. The most important method of effecting coagulation is by addition of an electrolyte. When the electrolyte is added gradually, coagulation takes place suddenly at a certain concentration—the so-called saturation value ("*Schwellenwert*")—which varies with different colloids and with different electrolytes. According to Freundlich (this J., 1907, 646) coagulation is due to neutralisation of the charge carried by the suspended particles by adsorbed ions. As showing the effect of adsorbed ions it may be mentioned that Lottermoser (J. prakt. Chem., 1905, **72,** 39; 1906, **73,** 374) obtained a negative silver iodide colloid by using 40 c.c. of $N/20$ $AgNO_3$ and 50 c.c. of $N/20$ KI and a positive colloid from 50 c.c. of $N/20$ $AgNO_3$ and 40 c.c. of $N/20$ KI, the charges being due to iodine ions and silver ions respectively. In a study of the reversible coagulation of colloidal sulphur solutions Oden (*loc. cit.*) found that the coagulating power of an electrolyte increases with its degree of dissociation: and that the "saturation value" becomes better defined with increasing uniformity of the size of the colloidal particles and also increases with rise of temperature. In the case of irreversible colloids the "saturation value" is not so well-defined, and coagulation frequently takes place at some distance from the isoelectric point. A colloid can be coagulated by addition of another colloid of opposite electric charge, but complete precipitation occurs only when the two colloids are present in a definite proportion. Irreversible colloids can be converted into reversible ones by addition of a small quantity of a reversible colloid of like electric charge. Metal sols can be made reversible, for example, by addition of gelatin, albumin, or the like.

Intimately connected with the extensive surface of colloids is their catalytic activity, one of the chief factors in which is probably adsorption by the colloidal particles. Bredig (this J., 1900, 1155; 1901, 376) pointed out the great similarity between the catalytic action of colloidal platinum and that of enzymes, the catalytic decomposition of hydrogen peroxide by colloidal platinum, for instance, being inhibited by certain substances (hydrocyanic acid, hydrogen sulphide, phosphorus), which also act as poisons to organic enzymes. The colloidal solutions of the platinum metals prepared by Paal (this J., 1902, 994; 1904, 208) by addition of organic protective colloids possess great catalytic activity, and with the aid of colloidal palladium and, more especially, of palladium-hydrogen, a large number of important reductions has been effected by Paal, by Willstätter (this J., 1908, 642, 829) and by Wallach (Nachr. Kgl. Ges. Wiss. Göttingen, 1910, Math.-phys. Kl.). Reduction is effected merely by exposing a mixture of colloidal palladium solution and a neutral aqueous or alcoholic solution of the substance to be reduced to the action of hydrogen gas, and the method has already acquired considerable importance for the synthesis of hydrogenised organic compounds and the detection of double linkages.

The study of colloidal systems having a gaseous dispersion medium has been pursued most successfully in England. As a result of the work of Townsend (1897), J. J. Thomson (1893—1899) and, especially, of C. T. R. Wilson (1897—1912), it has been demonstrated that the formation of fog is due chiefly to condensation of water vapour on gaseous ions, and the experimental formation of mist or fog in this way has proved one of the most valuable methods of investigating ionisation in gases.

Of colloids with solid dispersion medium, ruby glass has been thoroughly investigated by Zsigmondy and Siedentopf (Ann. der Physik, 1903, [4], **10,** 2). It is noteworthy that many of the most beautiful colour phenomena known are caused by the presence of colloids. The magnificent play of colours frequently observed at sunset is due to colloidal particles of dust and moisture in the atmosphere; and the colour of ruby glass and of many precious stones is due to colloidal metal particles. The colour of blue rock salt, for example, is due to colloidal sodium; sapphire and amethyst are solid colloidal solutions, and opal is a solid silicic acid gel. It is also extremely probable that the finer structure of many metals is due to solid colloidal solutions.

Practical applications of the results of the investigation of colloids are numerous. In the case of biology and medicine, for example, the work of M. H. Fischer on nephritis (*Die Nephritis*, Dresden, 1912) may be cited, which led to a simple method of treating this disease. The value of colloid-chemical considerations in geology and mineralogy has been shown by Doelter (Kolloid-Zeits., 1909—1912) and by Cornu (Kolloid-Zeits., 1905). The study of colloids is of great importance for agriculture, for some of the most important properties of soils, *e.g.*, their power of retaining moisture and fertilising salts, are due to the presence of colloids. Lüppo-Cramer's colloid-chemical studies of the photographic process (*Kolloidchemie und Photographie*, Dresden, 1908) have shown that it is probable that the latent image consists of ultramicroscopic silver particles, which serve as nuclei in the subsequent development. Results obtained in investigations of the mutual precipitation of colloids have thrown a considerable amount of light on the problem of sewage purification. The study of colloids will undoubtedly become of increasing importance in such branches of industry as dyeing, brewing, soap-making, ceramics, and rubber, in which the products dealt with are mainly colloids (see Arndt, *Die Bedeutung der Kolloide für die Technik*, Dresden, 1911).—A. S.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows :—
English.—8*d*. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s*. each, to the Secretary of the Society.
French.—1 fr. 05 c. each, as follows : Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.) ; Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

I.—GENERAL PLANT; MACHINERY.

Power production from gas engines. Utilisation of waste fuels. Coster. *See* IIA.

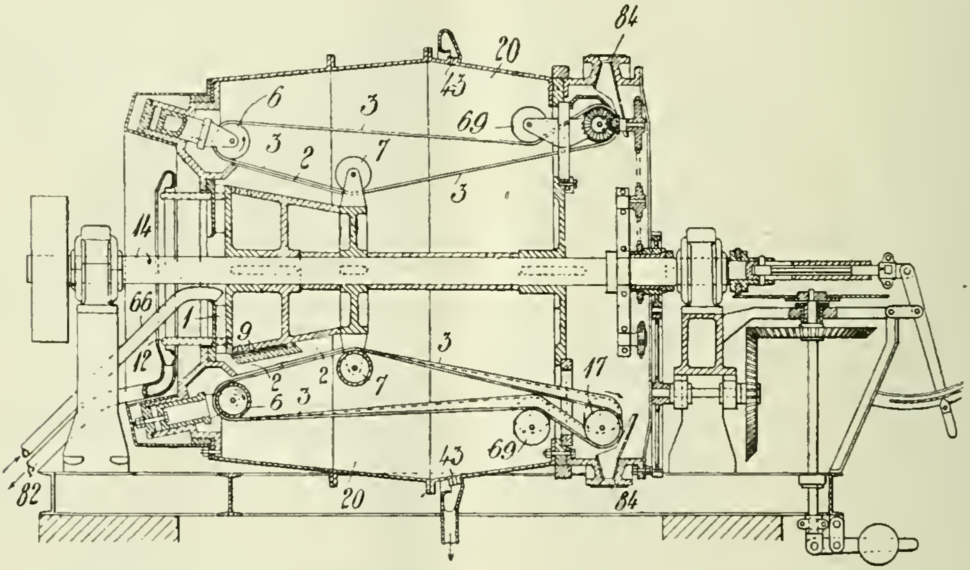
PATENTS.

Pressure filters. J. A. Muirhead, Tadcaster, Yorks. Eng. Pat. 24,768, Oct. 31, 1913.

THE joint between the elements of a cylindrical pressure filter for beer and the like is made by a rubber ring of circular cross-section which fits into a corresponding recess formed on one side of the plates near the periphery. A circular rib formed on the opposite side of the adjacent plate presses against the rubber ring.—W. H. C.

Separators or dryers; Centrifugal ——. K. and A. Ward, Stockholm, Sweden. Eng. Pat. 10,783, May 1, 1914. Under Int. Conv., May 8, 1913.

THE mixture of solids and liquid enters the separator through the pipe, 66, and passes through the channel, 1, to the separation chamber, 2. The inner wall of this chamber is rotated on the shaft, 14, and the outer wall is formed by a series of endless bands, 3, which pass over the rollers 6, 7, 17, 69, the angle at which the band is set being adjustable. The whole is enclosed in the outer drum, 20, which is also rotated on the shaft, 14. The greater part of the liquid passes through the ports, 9, and away by the pipes, 12, 82. The solids are carried forward by the bands, 3, more liquid being separated, which is finally discharged through 43. The solids are carried forward over the roller, 17, and are discharged through 84.—W. H. C.



Stone, grit, sand, etc. ; Drying and heating of ——. T., A., T., and F. Coleman, Derby. Eng. Pat. 3103, Feb. 6, 1914.

THE material is fed to the middle, and is thrown off the periphery, of a dished rotating disc surrounded by a funnel which leads it to the middle of a second disc on the same vertical shaft as the first. It meets an ascending current of hot gases passing up through a casing containing a system of discs and funnels.—O. E. M.

Drying apparatus. E. B. Stone, Assignor to The American Hardware Corporation, New Britain, Conn. U.S. Pat. 1,117,720, Nov. 17, 1914 ; date of appl., Dec. 30, 1913.

THE articles to be dried are conveyed by a worm along a horizontal perforated tube while being sprinkled with drying material contained in a surrounding rotating casing furnished with internal wings.—O. E. M.

Oils and other liquids ; System for cleaning and purifying ——. R. S. Johnson, Cleveland, Ohio, Assignor to S. F. Bowser & Co., Fort Wayne, Ind. U.S. Pat. 1,115,827, Nov. 3, 1914. Date of appl., July 23, 1913.

A NUMBER of settling tanks are connected in series and the dirty oil is passed through them by means of a pump. Pipe connections and valves are provided so that any of the tanks may be cut out of the series and the oil may be transferred by the pump from one tank to any other. —A. T. L.

Evaporating apparatus. T. F. Sanborn, New York. U.S. Pat. 1,116,927, Nov. 10, 1914 ; date of appl., April 19, 1913.

EVAPORATING cells are made polygonal in plan so that they may be grouped together to give a single cell of larger capacity.—O. E. M.

Still. A. G. Duncan, Joliet, Ill. U.S. Pat. 1,116,578, Nov. 10, 1914 ; date of appl., June 16, 1913.

THE still is divided into sections by horizontal plates upon which the liquid is retained by damming walls. Sealing walls attached to the under side of the partition above, and dipping into the liquid, constrain a current of gas forced into the section to pass through the liquid. —O. E. M.

Gas-fired furnaces; Apparatus for increasing the temperature of combustion in ——. H. L. Doherty, New York. U.S. Pat. 1,117,172, Nov. 17, 1914; date of appl., April 4, 1912.

A gas-heating recuperator above an air-heating recuperator is placed on each side of a furnace or generator. —O. E. M.

Suspended matter: Means for removing particles of —— from bodies of fluid. W. W. Strong, Pittsburgh, and A. F. Nesbit, Wilkinsburg, Assignors to R. B. Mellon, Pittsburgh, Pa. U.S. Pat. 1,117,531, Nov. 17, 1914; date of appl., Feb. 11, 1913.

The fluid is passed up an earthed central tube and out through lateral extensions in which high-potential electrodes are fixed.—O. E. M.

Drying of liquids and vapours. Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. Eng. Pat. 27,239, Nov. 26, 1913. Under Int. Conv., Nov. 30, 1912.

See Fr. Pat. 465,504 of 1913; this J., 1914, 643.—T. F. B.

Separator; Centrifugal ——. E. Köpke, Honolulu, Hawaii. U.S. Pat. 1,117,195, Nov, 17, 1914. Date of appl., Jan. 17, 1914.

See Fr. Pat. 467,981 of 1914; this J., 1914, 1023.—T.F.B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Gas coke for steam-raising. E. W. L. Nicol. J. Gas Lighting, 1914, **128**, 424—425.

The results of analyses and determinations of calorific value are quoted, showing the comparative fuel values of various kinds of coal and coke obtained in London. The figures for coals varied from 95,760 B.Th.U. per penny cost for a Welsh coal, containing 87·3% fixed carbon, 3% ash, 4% hydrogen, and costing 29s. 6d. per ton, to 111,000 B.Th.U. per penny for anthracite, containing 92% fixed carbon, 3% ash, 3% hydrogen, at 25s. per ton, and 129,800 B.Th.U. per penny for washed bituminous nuts, with 45·6% carbon, 10% ash, 5·45% hydrogen, and about 10% moisture, at 17s. 6d. per ton. For gas coke, from good quality coal, broken and graded, the figures ranged from 121,800 to 146,700 B.Th.U. per penny cost, according to price (16s. 8d. to 20s. per ton): in each case the coke contained 88% fixed carbon, 8% ash, and 0·5% hydrogen; "average" gas coke gave values from 111,600 to 134,400 B.Th.U. per penny according to price (same limits); this contained 86% fixed carbon and 0·5% hydrogen. The London Coke Committee recommend for use with coke in boilers fitted for coal firing, a forced-draught apparatus working on the steam-jet injector principle. That coke can replace coal with advantage for steam-raising is shown by the case of an electric lighting station, which had previously obtained an average evaporation of 5·9 lb. of water per pound of fine coal slack; using broken coke under similar conditions, an average of over 8 lb. of water per pound of fuel has been obtained.—T. F. B.

Power production from gas engines. The utilisation of waste fuels. A. V. Coster. Times Eng. Suppl., Nov. 27. 1914, 157.

The author pointed out the advantages of the gas engine, owing to its ability to utilize waste fuels and gas, for the production of power, and urged the need for manufacturers in this country to follow Germany in making the utmost use of such resources. Calculations based on an output of 10,000,000 tons of pig iron annually, show that power resources which would yield fully 1,000,000 electrical h.p. for power and lighting purposes are being wasted, and that of the 30,000,000 tons of coal used annually in the British iron and steel industries a large proportion is wasted. On the other hand, in the iron districts of Westphalia and Rhineland practically no power gas is wasted, and cheap electrical power is available for all manufacturing purposes. At the Krupp works there are 26 gas engines running on blast furnace gas and developing 36,000 electrical horse-power per hour. Under working conditions the following consumptions have been obtained with gas engines and producers per b.h.p. per hour.—Coke-breeze and charcoal, 1 lb.; peat briquettes, 1·25 lb.; lignite, 1·75 lb.; cotton seed, 2·5 lb.; peat, 3·3 lb.; and bark refuse containing up to 50% H_2O, 4 lb. But the thermal advantages of the gas engine are not confined to the utilization of waste products. With ordinary grades of coal and coke, if the calorific value of the fuel as supplied to the boiler or producer is taken as 100, then 25·8% of the heat is converted into useful work in the gas-engine, against 13% in the steam-engine, so that with engines working at from three-quarters to full load the thermal efficiency of the former is about twice that of the latter. The reduced weight of fuel that must be handled per h.p. and the reduced attention required at the gas producer are also in favour of gas. Standby losses, again, are at least 75% less than in a steam installation, the admission of air through a 1-in. hole being sufficient to maintain combustion over a long week-end in a 500 h.p. gas producer; and the cost in wages involved in starting up a power plant is also greatly reduced, as gas sufficient to start the engine can be obtained in about a quarter of an hour.

When blast-furnace or coke-oven gas is available the advantages of the gas-engine become enormous. At the Cockerill works, near Liége, all the power is developed from blast-furnace gas, and allowing annual depreciation equal to 13% of the cost of the installation, with 4380 working hours a year, corresponding to a load factor of 50%, the total cost per kw. is 0·183d. In a blast furnace having a capacity of 20 tons a day and consuming 10 tons of coke an hour the waste gas produced is sufficient to generate 10,000 b.h.p. by gas-engines. Of this 2500 h.p. are required for air supply, transport, lighting, etc., and the remaining 7500 h.p. are available for driving rolling mills or generating electricity, which may be sold. A coke-oven with a capacity of 200 tons per 24 hours and consuming 10 tons of coke an hour generates enough gas to develop 1800 to 2000 b.h.p. in gas-engines; and, further, by using the waste coke (coke smalls) in a gas-engine 900 b.h.p. are obtained in addition, so that close upon 3000 h.p. are available continuously.

Anthracite; Preservation of —— under water. R. D'Estape. L'Ind. Chim., Min. e Met., 1914, **1**, 446—447.

A circular magazine of reinforced concrete provided with pipes for drawing off water and a door for removing the coal was filled to about two-thirds of its capacity (3200 tons) with ungraded coal, the remaining portion being divided into three parts filled respectively with ungraded coal containing 40% slack, small pieces, and large lumps. After 20 days under water the coal had only absorbed 0·7% moisture, while the amount of water adhering to the surface was 15 to 20% in the case of the slack, 2 to 3% on the small pieces, and 1·5% on the large lumps. After several months' storage the water was drained off for 7½ days, and the coal at the bottom of the magazine then contained 8·8% water and 5% when it reached the sheds. After 10½ days' drainage the respective quantities before and after reaching the sheds were 6·2 and 5·2%. The conclusion is drawn that coal that has been stored under water is ready for use within 3 to 4 days after the water has been drained off.—C. A. M.

Catalysis in the gas industry. R. Lessing. J. Gas Lighting, 1914, **127**, 570—573.

Coal dust or the mineral matter in coal appears to act as a catalyst in effecting oxidation of coal at ordinary temperatures, and this action becomes much more marked at the high temperatures of gas retorts. The types of reactions and decompositions which occur in these retorts are known to be liable to catalytic influence. Catalytic material is amply furnished by the mineral matter of the coal, the composition of which has been little investigated except in the oxidized state in which it appears in the ash. The retort material probably has a catalytic action, depending on its chemical composition and whether its surface is smooth or porous or more or less covered with retort carbon. The lime which, according to Cooper's process, is added to coal before carbonization doubtless acts catalytically in accelerating the primary formation of permanent gas and of tar vapours which do not readily decompose, as well as in increasing the yield of ammonia. In water-gas plant lime and other catalysts may promote the hydrogenation of the oxides of carbon into methane. Catalysis also plays an important part in gas purification, especially in the process perfected by Carpenter in collaboration with Evans and Franks, by which the carbon bisulphide in the gas is converted into hydrogen sulphide by nickel at about 430° C. Examples are also quoted to show that catalysis comes into play in the working up of many by-products of gas manufacture and in many modes of application of gas.

Fuels; Review of recent work on ——. D. Meneghini. Annali Chim. Appl., 1914, 2, 251—275.

The separation of unconsumed coal, etc., from furnace ashes and cinders by utilising the different specific gravities of the mineral (2·5—3) and carbonaceous constituents 1·3—1·5) respectively, has been tried successfully (Velten, Rev. Gén. d. Sci., 1913, 216), 38 tons of coke containing 84% of combustible matter and having a heating value of 6500 cals. being recovered from 2000 tons of furnace residues. A product of lower calorific value, but which can be utilised in gas producers, can also be recovered.

Schilling (Z. Ver. deuts. Ing., 1913, 668) has compared the results obtained with the older and more modern types of gas retorts :—

	Date.	Per furnace for 24 hours.			Per 100 tons (metric) of coal per 24 hours.			
		Coal carbonised.	Gas produced.	Coke for heating.	Gas produced.	No. of furnaces.	No. of workmen.	Coke for heating.
		metric tons.	cb. metres.	metric tons.	cb. metres.			metric tons.
Inclined retorts	1884	10·8	3240	1·6	30,000	10	15	14
Dessau vertical retorts :—								
Old type	1903	12·0	4000	1·7	33,000	8	9	14
New type ..	1911	23·0	8000	3·2	35,000	4·4	4	14

Ab-der-Halden (Soc. Techn. du Gaz, June, 1913) found that by extracting soft pitch with petroleum ether, 42% of high-boiling oils could be removed, and by repeated extractions with petroleum ether, toluene, and carbon bisulphide, a residue consisting of a brown powder (H 94·32, C 4·06%), m. pt. 193° C., was obtained. This substance plays an important part in the formation of tar, serving to emulsify the "free carbon." It decomposes at 400° C., leaving a hard, dense, carbonaceous residue.

To overcome the difficulties attending the use of American coals in gas producers owing to the fusibility of their ash, it has been proposed to produce an endothermic reaction (*e.g.* decomposition of carbon dioxide) in the zone of maximum temperature, and this has been effected by mixing combustion gases with the air supplied to the producer; in practice a mixture of air and combustion gases containing 9% CO_2 is used (Rev. Gén. Sci., 1913, 334).—A. S.

Inflammability of mixtures of methane and air; The limits of ——. M. J. Burgess and R. V. Wheeler. Chem. Soc. Trans., 1914, 105, 2591—2596.

Mixtures of purified methane and air were ignited by sparking in a large glass globe, and in sealed glass cylinders 6 cm. in bore by 200 cm. long. The limits of inflammability were :—

	Methane, %.	
	Lower limit.	Higher limit.
Central ignition in large globe	5·6	14·8
Vertical tube, closed at both ends :—		
(A) Ignition at bottom	Not less than 5·40	Not more than 14·8
(B) Ignition at top	6·0	13·4
Horizontal tube, closed at both ends :—		
Ignition at one end ..	5·4 (flame travels only along top of tube) 5·6 (methane all burnt)	14·3

The appearances of the flames are indicated by diagrams. Under condition (A) flares of flame were produced which travelled increasing distances upwards as the methane-content was gradually raised from 5%, until at 5·4% the whole length of the tube (200 cm.) was traversed; similarly, 5·35, 5·3 and 5·25% CH_4 corresponded to distances of 50, 40 and 30 cm. respectively. From the results obtained with horizontal tubes of 6 and 10 cm. bore it is concluded that in a large space filled with a mixture containing 5·4% CH_4, ignition at the bottom would result in a narrow column of flame travelling upwards and spreading along the upper boundary only of the space. Similarly, slow ascending currents of air containing 3 or 4% of coal-gas conveyed small caps of flame along a tube; such mixtures are potentially dangerous as being capable of firing richer mixtures. The lower limit of inflammability fell below 5·0% in well agitated mixtures of methane and air contained in a 4-litre globe. The criteria of inflammability for downward propagation and propagation throughout a globe are emphasised as preferable to the criterion depending upon upward propagation as recommended by Coward and Brinsley (this J., 1914, 851).—J. R.

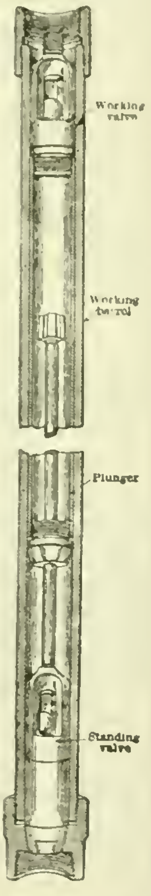
Flames; The propagation of —— *in "limit" mixtures of methane, oxygen and nitrogen.* M. J. Burgess and R. V. Wheeler. Chem. Soc. Trans., 1914, 105, 2596—2605. (See also preceding abstract.)

"Lower-" and "higher-limit" mixtures are defined as "such that a given volume must, under the conditions of its combustion, evolve just sufficient heat to raise an equal volume to its ignition-temperature." The speed of travel of the flame is stated to be constant for horizontal propagation in all limit mixtures of methane, oxygen and nitrogen. Ignitions of such mixtures were carried out in a 2½-litre glass globe, and in each case the flame gases (withdrawn through a capillary tube) and the final gases were analysed. As the oxygen-content was reduced the two limits approached: with air, the limits were 5·60 and 14·82% CH_4, respectively; with 17·00% O_2 (and 83·00% N_2) the limits were 5·80 and 10·55% CH_4; with 13·45% O_2 (and 86·55% N_2) the limits were 6·50 and 6·70% CH_4; and in an atmosphere containing only 13·25% O_2 all proportions of methane were incapable of propagating flame. The essential reaction concerned in the propagation is $CH_4+O_2=CO+H_2+H_2O$. With increasing proportions of oxygen more and more of the methane is completely burnt to carbon dioxide.

Preferential burning of hydrogen over carbon monoxide occurred in all mixtures containing a ratio $O_2 : CH_4$ greater than 1·5. With ratios not less than 2·0 the ignition-temperature is calculated as 650° C., whereas with continued increase in the methane-concentration up to the higher limit, $O_2 : CH_4 = 1·20$, the ignition-temperature rose gradually to 715° C.—J. R.

Oil recovery in California; Methods of ——. R. Arnold and V. R. Garfias. U.S. Bureau of Mines, Techn. Paper 70, 1914, pp. 1—57.

The Californian oil-wells vary in depth from 200 to 4000 ft., and very few of the wells yield oil by natural flow. In a few cases the oil is raised by blowing compressed air into the lower part of the tubing which reaches to the bottom of the well, and this method is suitable for oil and water mixtures containing much sand (not exceeding 20%) which rapidly wears pump valves and barrels. The exhaust steam from the air-compressing plant is used for heating the oil to a temperature at which the water separates from it. The up-keep and operating costs are low. The production of the wells, however, often decreases after a time when the oil is raised by air-lift, and the lowering of the water-level in the strata increases the required lift so that the air-pipe must be submerged further and the working becomes increasingly uneconomical after the air-pipe has been lowered to the bottom of the well. In the great majority of wells, the oil is raised by plunger pumps. The working barrel (see fig.) is 66—84 in. long and 1¾—3¾ in. inside diameter, and is screwed to the lower end of tubing which extends down into the well. The plunger is a seamless steel tube, ground to fit the barrel. Cup or other packing is used when the barrel has become worn. The plunger carries a tool-steel ball valve at the upper end, and a similar valve for the suction is provided at the bottom of the barrel and can be removed with the plunger for renewal without removing the tubing. The plunger is operated by steel tension rods, screwed together in 20 ft. lengths, or sometimes by wire rope or wooden rods. The life of the tubing under ordinary conditions is usually 4 years. The pumping stroke is 20—35 ins. (average 23 ins.) and the speed 15—30 strokes per min. (average 20). The average capacity of a 2¾ in. pump is theoretically 400 barrels per day, but lower results are obtained in practice owing to leakage. Of 5759 wells using plunger pumps, 2631 use steam engines, 869 use electric power (generated from mountain streams), and 2259 use gas engines. The fuels used for steam raising are oil, natural gas, and wood. Natural gas is however used much more economically in gas engines, the consumption of gas per I.H.P.-hour being 13 cb. ft. in an ordinary gas engine, and 130 cb. ft. with steam-power plant as ordinarily used for pumping oil-wells. Diesel engines are very seldom used.—A. T. L.



Flames; The propagation of —— *in mixtures of methane and air. The "uniform" movement.* R. V. Wheeler. Chem. Soc. Trans., 1914, 105, 2606—2613.

When mixtures of methane and air contained in a horizontal tube closed at one end are ignited at the open end, the flame travels for a short distance at a uniform speed; but eventually this "uniform movement" is always succeeded by a "vibratory movement." For the slowest flames investigated a tube of at least 5 cm. bore was necessary in order to avoid retardation due to cooling by the walls. The duration of the uniform movement depended upon the composition of the mixture and increased with the diameter and length of the tube up to a definite maximum: in a tube of 5 cm. bore the extent of the movement was 150 cm. in a 6-metre tube and only 50 cm. in a 2-metre tube. The speed was 35·5 cm. per second at both the lower and the higher limit of inflammability (see preceding abstracts); from each of those limits it rose, in mixtures with intermediate methane-content, first slowly then rapidly to a maximum value of about 112 cm. per second; this value remained practically constant for mixtures with 9·45 to 10·55% CH_4. The velocity was measured by means of a chronograph actuated electrically by the successive fusion of thin copper screen-wires placed in the path of the flame at distances of 50 cm. apart. In a tube of 9 cm. bore the speeds were from 5 to 10 cm. per second greater.—J. R.

Natural gas mixtures; Explosion limits of ——. Z. Z. Biluchowski and Z. Lahocinski. Petroleum, 1914, 9, 605—606.

The explosion limits were determined by sparking mixtures of gas and air in a Hempel pipette. Mixtures containing 7·55 to 9·1% of combustible gas were explosive; the corresponding limits for methane were 3·7—9·0, and for petrol vapour (from a light spirit of sp. gr. 0·622), 2·9—8·1%. —A. T. L.

Petroleum; Researches on the products of destructive distillation of crude Bustenari —— *and its derivatives.* C. Petroni. Diss., Bucarest, 1914. Petroleum, 1914, 9, 1377—1378.

The oils subjected to destructive distillation were crude (Roumanian) petroleum (from the "Vega" works in Ploesti), and the crude benzine, lamp oil, and solar oil fractions, together with the extract obtained from the lamp oil fraction by means of liquid sulphur dioxide. Minimum yield of gas and maximum of tar were given by the sulphur dioxide extract and the solar oil fraction; maximum gas and minimum tar by the benzine; the lamp oil fraction and the crude oil gave intermediate yields. In the case of benzine and lamp oil light liquid hydrocarbons were carried off with the gases, reducing the amount of tar; moreover, the presence of these fractions in the crude oil, together with the coke produced from certain heavy oils present, account for the low yield of tar from the crude oil. The solar oil tar contained much more benzene and toluene than the tar from the sulphur dioxide extract, which was composed mainly of aromatic hydrocarbons with side-chains, the latter, with the exception of the methyl group, being split off from the benzene nucleus at 740°—770° C. The yield of hydrocarbons boiling between 115° and 205° C. was, from the extract-tar, 24·33%, and from the other tars only 8—10%. The differences in the yields of naphthalene and anthracene were not very great; naphthalene varied from 8 to 12%, anthracene from 1·5 to 2%. Lubricating oil tars and residues yielded 3 to 4% of naphthalene and 0·5 to 0·6% of anthracene. From the commercial standpoint the sulphur dioxide extract would appear to be the most suitable product for destructive distillation. The 26·2% of liquid aromatic hydrocarbons obtainable from its tar have considerable commercial value, and in addition naphthalene and anthracene are obtained in large quantities. As compared with coal-tar the yield of light hydrocarbons is ten times, that of naphthalene twice, and that of anthracene equally as great, and the purity of these three products is much greater than that of those derived from coal-tar.—E. W. L.

Gasoline: Testing of ——. A. P. Lidoff and G. W. Petroff. Neftjanoje Djelo, 1913, No. 13. Petroleum, 1914, 9, 614—615.

The specific gravity is not a sufficient indication of the suitability of a sample of gasoline for any given purpose, since the chemical composition of samples of the same specific gravity is different for oils of different origin. The constituents may include, besides the normal saturated hydrocarbons, C_nH_{2n+2}, the isomerides of these hydrocarbons and the naphthenes, C_nH_{2n} (cyclo-pentane, etc.). The best method of examination at present available is by fractionation. A rough test of inflammability may be made by determining the flash-point of a mixture containing 20—5% gasoline and 80—95% of refined paraffin oil.—A. T. L.

Oil-cooled transformers; Formation of deposits in ——. A. C. Michie. J. Inst. Elect. Engineers, 1913, **51**, 213—218.

Samples of sludges from transformers contained lead or traces of manganese derived from the varnish of the windings, but in most cases they had apparently been formed by oxidation and polymerisation of the oil itself. One sample contained: C 76·0, H 7·1 and O 16·9%. To test the liability of transformer oils to become oxidised, 100 c.c. of the sample were placed in a 200 c.c. flask with a neck 11½ in. long, which was surrounded by a tube through which was passed a current of cold water. The flask was immersed in an oil-bath kept at 150° C., whilst a current of purified air was drawn through the oil for 45 hours or longer at the rate of 0·07 cb. ft. per hour. Usually a piece of copper foil (4½ sq. in.) was placed in the flask to promote the oxidation, and the resulting deposits (0 to 2·5%) were separated, washed with petroleum spirit and weighed. The composition of the deposits closely resembled that of the transformer deposits, and, like them, they were nearly insoluble in petroleum spirit but soluble in benzene. Their m.pts. ranged from about 70° to 220° C. A heavy deposit was obtained in a relatively short time at 90° C. when ozonised air was drawn through the flask. The rate of formation of the deposit was accelerated by the presence of certain metals, notably copper. Thus the following amounts separated in 45 hours from an oil treated as described above in the presence of the following metals (area, 4½ sq. in.):—Air alone, 0·28; Cu, 0·94; Fe, 0·88; Sn, 0·7; Pb. 0·57; Ni, 0·3; and Zn, 0·28%. The deposit formed in the presence of copper was free from that metal, but in the case of lead the deposits were of a pale yellow colour and contained lead (*e.g.* 36%). The amount of sludge separating depends upon the degree of purity of the oil. Treatment with sulphuric acid or caustic soda, or filtration through fuller's earth, removed unsaturated or readily oxidisable substances from the oils. Thus after such refining the amount of deposit formed by an oil was reduced from 1 to 0·1%. Numerous commercial oils gave no deposit in the oxidation test after 45 hours at 150° C., and one sample withstood the test for 150 hours. To prevent or minimise the formation of deposits in transformers it is necessary to avoid over-heating, undue access of air to the oil, conditions leading to the formation of ozone, and contact of the oil with clean surfaces of copper, iron or lead. (See also this J., 1913, 1000; 1914, 951.) —C. A. M.

Asphaltums; Methods for determining the melting points of ——. J. G. Miller and P. P. Sharples. Proc. Amer. Soc. Testing Materials, 1914, **14** [Reprint.] 6 pages.

Comparative determinations of the m.pt. of different samples of asphaltum showed that the method of heating a half-inch cube of the material in an oil-bath is not satisfactory owing to the small range of temperature, and the fact that certain samples are heavier than the oil. Hubbard's method (*Dust Preventives and Road Binders*, p. 351) of heating the cube suspended from wire (No. 12 B. and S. gauge) at a height of 1 in. from the bottom of an air-bath at the rate of 9° F. (5° C.) per min. gave good results both with pitches and asphaltums. Various modifications of the "ring and ball" method are used in commercial specifications. In these the m.pt. is taken when a steel ball (⅜ or ½ in. in diameter) touches the bottom of the apparatus. The discrepancies between the results given by these modifications were found to be due to essential differences in detail, such as the dimensions of the apparatus and the rate of heating; and standardisation of all details is necessary if comparable results are to be obtained. It is suggested that the rate of heating should be 5° C. per min. (see also this J., 1914, 470).—C. A. M.

Naphthenic acids; Study of the ——. (*Preliminary communication.*) I. Pékoff. J. Russ. Phys.-Chem. Soc., 1914, **46**, 178. Bull. Soc. Chim., 1914, **16**, 784—785.

From the naphthenic acid fraction having a b. pt. corresponding to the hexahydrotoluic acids, amides were produced which, after crystallisation from water, had a m. pt. of 124°—128° C.; by fractional crystallisation of the latter an amide melting at 221°—221·5° C. was obtained. The amide of *m*-hexahydrotoluic acid obtained by Markownikoff in 1893 (m. pt. 156°—155° C.) was found to consist of two stereo-isomerides, one of which fused at 221°—221·5° C., and was identical with that prepared from the naphthenic acids.—W. Coal or other fuel; Apparatus for preparing and sorting comminuted or powdered ——. T. M. Coyle, St. Louis, U.S.A. Eng. Pat. 25,291, Nov. 5, 1913. Under Int. Conv., Sept. 3, 1913.

Powdered coal from a grinder is taken up by the suction of a fan or blower and delivered with the air current into a cyclone or other dust separator. The air escapes from this separator into a chamber, enclosed by cheese-cloth or fine gauze, arranged beneath the air-inlet bell on the suction side of the fan. The dust from the separator discharges into a sorter, which comprises a rectangular casing divided into two compartments by a vertical partition having openings regulated by flap-valves. A fan connected with the outlet of the sorter draws a current of air from adjustable orifices in the outer wall, transversely through one compartment and through the openings in the partition into the second compartment. The dust entering the first compartment falls on to deflecting plates which are inclined downwards alternately from the opposite walls, and the lighter particles are carried by the air current into the second compartment, where part is deposited, the remainder being collected in a cyclone separator. The heavy particles which collect in the first compartment of the sorter are returned to the grinder. —A. T. L.

Fuel and other briquettes and of briquette and other binders; Manufacture of ——. D. J. Davis, Balham, J. T. Armstrong and J. Mordan, Hughenden, and Petroleum Solid Fuel (Parent) Co., Ltd., London. Eng. Pat. 22,738, Oct. 8, 1913.

A binder suitable for the manufacture of fuel briquettes or for road-making purposes is made by mixing the natural bitumen, gilsonite, with crude Mexican, or other suitable bituminous oil, or with tar. A hardening substance, *e.g.*, iron chloride, may be added if desired.—W. H. C.

Fuel blocks. J. E. G. M. de Jouffrey, Chasselay, France. Eng. Pat. 14,589, June 17. 1914. Under Int. Conv., June 18, 1913.

Finely ground coal is mixed with 4—6% of an agglomerant capable of vitreous fusion at about 200° C., heated with high-pressure steam to about 170° C. and briquetted. The agglomerant is composed of fine glass maker's sand

5 parts, sodium carbonate or other salt capable of forming a flux with the sand, 10 parts, and extra fine Portland cement, 18 parts.—W. H. C.

Lignum vitae sawdust ; Method of utilising ——. [*Manufacture of firelighters*]. J. Forshaw, West Kirby, Cheshire. Eng. Pat. 1292, Jan. 17, 1914.

Lignum vitae sawdust is compressed into moulds and heated to 160° F. (71° C.) whereby the natural resin exudes and converts the sawdust into a coherent mass which ignites and burns easily.—W. H. C.

Steam generated by quenching coke ; Method of and means for utilising ——. H. Koppers, Essen-on-the-Ruhr, Germany. Assignor to H. Koppers Co., Chicago, Ill. U.S. Pat. 1,116,297, Nov. 3, 1914. Date of appl., Oct. 28, 1913.

The steam is used for heating water which is afterwards brought into intimate contact with the air supply of a gas producer.—A. T. L.

Gas-producers. C. M. Garland, Chicago, Ill. U.S. Pats. (a) 115,804 and (b) 1,115,805, Nov. 3, 1914 ; dates of appl., Dec. 19, 1913, and May 2, 1914.

(a) The producer has a rotary intermediate generator chamber, and on the upper part of the fixed cover of this a fuel-supply chamber of flattened or oval section is mounted eccentrically so that as the intermediate chamber rotates an annular gas passage of triangular section is left above the fuel. This passage communicates with a gas discharge pipe also mounted eccentrically on the upper plate. (b) A fixed stepped ash-supporting table is surrounded by a rotary shell. The stepped table is provided with openings for the introduction of the blast and has saw-teeth mounted on the steps which serve to agitate the fuel as the shell rotates.—W. H. C.

Gas-producer. P. G. Schmidt, Olympia, Wash. U.S. Pat. 1,116,131, Nov. 3, 1914 ; date of appl., March 26, 1913.

In a producer having an intermediate rotary fuel chamber, air is supplied through a central pipe at the bottom and gas led off through an outlet pipe which depends from the top into the centre of the bed of fuel. A secondary supply of air is delivered through a water-sealed blast pipe to the periphery of the chamber above the level of the lower end of the gas-exit pipe.—W. H. C.

Gas from bituminous fuel ; Process of producing ——. O. C. Berry, Glendale, Ohio. U.S. Pat. 1,116,216, Nov. 3, 1914 ; date of appl., May 6, 1908.

The fuel is charged into a producer having the gas outlet intermediate between the top and bottom, and a sufficient proportion of the hot gas is drawn through the upper part of the producer to distil off the tarry vapours from the raw fuel. The mixture of vapours and gas is returned to the combustion zone either alone or mixed with air. —W. H. C.

Petroleum emulsions ; Treating ——. R. E. Laird and J. H. Raney, Taft, Cal. U.S. Pat. 1,116,299, Nov. 3, 1914. Date of appl., July 22, 1914.

The emulsion is "broken" by passing it upwards between electrodes which are brought intermittently to a sufficiently high potential difference to cause the conducting particles to coalesce in chains. When the potential difference is removed, these chains break up into "globules of free water."—A. T. L.

Briquette [*of coke dust*]. J. Alexander, Altona, Germany. U.S. Pat. 1,117,125, Nov. 10, 1914. Date of appl., Dec. 3, 1913.

See Fr. Pat. 461,065 of 1913 ; this J., 1914, 67.—T. F. B.

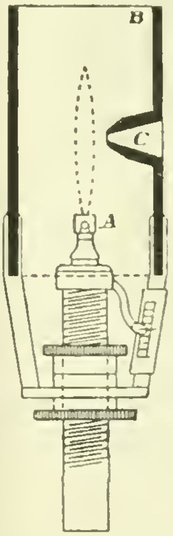
System for cleaning and purifying oils and other liquids. U.S. Pat. 1,115,827. *See* I.

Making ammonium phosphate [*for fertilising purposes, from gas liquor*]. U.S. Pat. 1,115,044. *See* XVI.

IIb.—DESTRUCTIVE DISTILLATION ; HEATING ; LIGHTING.

Light source ; New standard ——. L. A Jones. Amer. Illuminating Engineering Soc. J. Gas Lighting, 1914, 128, 430–431.

An acetylene burner of the type illustrated has been found to make a serviceable secondary photometric standard when accurately adjusted, though it is not reproducible to the precision necessary for a primary standard. The tip, A, is of the Bray air-mixing type, consuming 0·25 cb. ft. of gas per hour, giving a cylindrical flame about 3 mm. in diameter and 50 mm. high. The cylindrical metal hood, B, has a rectangular opening at C. from the edges of which metal leaves extend inwards to within about 2 mm. of the flame, forming an aperture, about 3 mm. high by 10 mm. wide. The acetylene used was purified by passing through bleaching powder and potassium chromate, and then carried through a regulator which kept the line pressure constant to within 2%. The advantages claimed for this type of standard are that it gives a good quality light of constant intensity, with but little attention.—T. F. B.



Patents.

Wood ; Apparatus for the destructive distillation of ——. S. E. Seaman, Brooklyn, N.Y. U.S. Pat. 1,115,590, Nov. 3, 1914. Date of appl., Dec. 27, 1913.

The wood is delivered into an inclined rotary retort from a separate hopper by means of a screw conveyor. The gases from the retort are cooled and passed through a condenser, and the uncondensed gases are passed through the hopper in order to remove air from the charge. —A. T. L.

Electric incandescence bodies suitable for use in glow lamps, and methods of manufacturing same. C. O. Bastian, London. Eng. Pat. 22,331, Oct. 3, 1913.

Closely-wound spiral filaments are formed by winding a coated wire or filament with successive turns in contact with one another, and removing the coating after the filament has been mounted on its final support in the lamp. A tungsten or molybdenum filament may be coated with oxide before winding ; the oxide being removed by passing current through the filament while the lamp bulb is being exhausted. A coating of copper deposited electrolytically may be used, and other suitable coatings are lime, cotton, varnish and collodion.—A. T. L.

Metallic filaments for electric lamps ; Manufacture of ——. A. Lederer, Vienna. Assignor to Westinghouse Lamp Co., Philadelphia. U.S. Pat. 1,116,450, Nov. 10, 1914. Date of appl., Nov. 11, 1910.

See Eng. Pat. 5388 of 1910 ; this J., 1911, 410.—T. F. B

III.—TAR AND TAR PRODUCTS.

Tar prices. J. Gas Lighting, Dec., 1914.

The Joint Committee of the Institution of Gas Engineers, representing tar producers and distillers (see this J., 1914, 1150), report that their efforts to fix the minimum price of pitch have failed, and therefore the proposed conditions for delivery of, and payments for tar during the war crisis are withdrawn. The Committee therefore recommend tar producers to make their own arrangements in regard to their tar contracts.

Phenol ; Compounds of calcium hydroxide with ——. F. F. Seliwanoff. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1535—1556. Bull. Soc. Chim., 1914, **16**, 224—225.

The most stable compound of lime and phenol is obtained as white flattened needles or square prisms by the action of aqueous phenol on calcium hydroxide or carbonate or metallic calcium. It becomes brown under the influence of moisture and light, but may be kept indefinitely in a sealed tube in absence of air. When dissolved in water, benzene, alcohol, ether, etc., it is decomposed into its components and it must be regarded as having the formula, $2C_6H_5OH,Ca(OH)_2$. When heated to 105°—120° C. in a dry inert gas, it loses one mol. of phenol ; the second mol. of phenol is displaced only at a higher temperature. The constitution, $HO.Ca.O.C_6H_5$, is ascribed to the monophenol compound, which is decomposed by water. It was not found possible to replace the hydrogen of the phenolic hydroxyl group by calcium ; metallic calcium has no appreciable action on fused phenol. Hydrates of the di-phenol-compound were prepared by various methods : they had the general formula : $2Ca(OH)_2,4C_6H_5OH,(2n+1)H_2O$, there $n=0$ to 4. By evaporating a solution containing 6·6 grms. CaO and 59·9 grms. C_6H_5OH per 100 c.c. in a vacuum exsiccator at 5°—8° C., crystals of $Ca(OH)_2,4C_6H_5OH$ were obtained, whilst solutions richer in phenol yielded crystals of $Ca(OH)_2,6C_6H_5OH$. Solid solutions of calcium hydroxide in phenol and also of magnesium hydroxide in phenol and of calcium hydroxide in thymol were also obtained.—A. S.

Pyridine ; Determination of ——. G. Malatesta and A. Germain. Boll. Chim. Farm., 1913, **53**, 225. Annali Chim. Appl., 1914, **2**, 277.

The official German method for the determination of pyridine is based on the formation of the cadmium chloride double compound, to which the formula, $CdCl_2,2C_5H_5N$, is ascribed. The authors find that this gravimetric method gives good results only if solutions of high alcohol concentration (at least 90%) be used and the formula, $CdCl_2,C_5H_5N$, be accepted for the double compound.—A. S.

Chlorination by means of aqua regia. Chlorination of benzene, thiophene, toluene, and mesitylene. R. L. Datta and F. V. Fernandes. J. Amer. Chem. Soc., 1914, **36**, 1007—1011.

Aqua regia is a convenient reagent for chlorinating hydrocarbons and other substances not easily oxidised by nitric acid. The mixture of hydrocarbon and *aqua regia* is warmed, with occasional agitation, the conditions being varied accordingly to the product desired. From 100 c.c. of benzene and 450 c.c. of *aqua regia* ($2HCl : 1HNO_3$) there were obtained by fractionation of the reaction product : unchanged benzene, 50 c.c. ; monochlorobenzene, 15 grms. ; *o*-dichlorobenzene, 4 grms. ; and *p*-dichlorobenzene, 18 grms. Thiophene yielded a mixture of about equal quantities of the mono-, di-, and tri-chloro-derivatives. From toluene, benzyl chloride and o- and *p*-chlorotoluene were obtained. Mesitylene yielded mainly the di- and tri-chloro-derivatives.—A. S.

Chlorination and oxidation by means of aqua regia ; Simultaneous ——. *Preparation of chloroanil from p-phenylenediamine and quinol.* R. L. Datta. J. Amer. Chem. Soc., 1914, **36**, 1011—1013. (See preceding abstract.)

Chloroanil can be prepared from *p*-phenylenediamine more simply and rapidly by the action of *aqua regia* than by the action of potassium chlorate and hydrochloric acid, according to Graebe's method (this J., 1891, 691). 15 grms. of *p*-phenylenediamine are added to 100 c.c. of *aqua regia* ($2HNO_3 : 3HCl$), the mixture being ultimately heated on the water-bath until all acid fumes are expelled. The product is washed with water, dried and sublimed : the yield is 10 grms. Quinol is also converted into chloroanil by the action of *aqua regia*.—A. S.

IV.—COLOURING MATTERS AND DYES.

Colour industry ; The artificial —— *and its position in England.* F. M. Perkin. J. Soc. Dyers and Col., 1914, **30**, 339—346.

After a brief review of the history of the coal-tar colour industry (compare W. H. Perkin, this J., 1885, 427), the causes which led or contributed to the decline of the industry in England are summarised thus :—The exploitation of the work of English chemists in Germany owing to the imperfect British patent laws and the lack of patent laws in Germany during the earlier stages of the industry ; slackness on the part of the early British manufacturers, after a certain period of prosperity ; industrial chemical research carried out in Germany but neglected in England ; German business organisation ; restrictions on the use of alcohol. The steps now being taken to establish the industry on a large scale in England are referred to (see this J., 1914, 1084), and it is suggested that the firms now manufacturing colours should enlarge their output and obtain leave to work certain German patents ; that many of the raw and intermediate products, such as benzene, naphthalene, anthracene, and their derivatives, should be manufactured at one or two of the great gas-works ; and that a few new companies should be started, preferably with capital furnished, at least in part, by colour users. In an industry such as that of the artificial colours, a number of highly-trained research chemists must be employed, as success will rest with the works capable of turning out the largest number of new colours and, at the same time, improving the methods of manufacture and the quality of the older ones and devising means of profitably utilising by-products. In this connection it is pointed out that the great profits made in the earlier stages of the industry by German firms were employed in the first case to write off capital expenditure and secondly to reconstruct their works and provide well-equipped laboratories staffed with skilled research chemists. The restrictions on the use of alcohol have been considerably mitigated (see this J., 1914, 1119), largely owing to the efforts of T. Tyrer, but it is stated that there is room for considerable improvement in the administration of the Government Acts. The use of pure alcohol is of even greater importance in the manufacture of drugs and photographic chemicals—an industry almost entirely in German hands before the war—than in the colour industry.—A. S.

Aminoazo-compounds ; Some ——. L. Casale and M. Casale-Sacchi. Gaz. chim. ital., 1914, **44**, II., 395—403.

The authors prepared by the usual method, aminoazo-compounds from α-naphthylamine and the diazo-compounds of some o-substituted aniline derivatives. The azo group proved to be in the para position with regard to the amino group of the naphthylamine. In the preparation of 4-*o*-tolylazo- and 4-*o*-anisylazo-1-naphthylamine, it was necessary to avoid excess of nitrite in preparing the diazo-compounds ; otherwise the free nitrous acid left in the solution diminished the yield of aminoazo-compound owing to secondary reactions, among which the formation of the corresponding hydroxyazo compound was observed. The preparation of 4-*o*-tolylazo-, 4-*o*-anisylazo-, 4-*o*-phenetylazo-, and 4-*o*-nitrophenylazo-1-naphthylamine, of their acetyl and benzoyl derivatives, and of *p*-naphthylenediamine by reduction of the tolylazo-compound with zinc and acetic acid is described.—A. S.

Eosin ; The copper lakes of ——. H. N. Gilbert. J. Phys. Chem., 1914, **7**, 586–618.

On mixing copper sulphate and sodium eosinate in aqueous solution, the copper lake was produced as a clear red solution, in suspension, as a precipitate, or as a jelly, depending on the conditions. When solutions containing equivalent quantities were mixed and allowed to stand, monoclinic crystals of copper eosinate were formed, and these could also be obtained by bringing together, in water, equivalent quantities of colloidal copper hydroxide and colloidal eosin (tetrabromofluorescein) : the crystals formed after three days. They were difficult to decompose by acids, and differed in properties from the ordinary amorphous copper lake of eosin. The latter is considered to be an adsorption compound of copper hydroxide with eosin, and eosin may be extracted from an aqueous suspension of the lake by shaking with ether. This is found to be due to the greater attraction of the copper hydroxide for the anions of certain salts. On shaking with acetone or alcohol the same change occurred and a precipitate of copper hydroxide formed.

A rapid and accurate method for the estimation of eosin compounds consists of adding sulphuric acid, extracting the liberated eosin with ether and estimating the amount by use of Wolff's colorimeter. A solution of cobalt nitrate containing 17·84 grms. $Co(NO_3)_2$ per litre has exactly the same colour as a solution of sodium eosinate containing 0·00125 grm. of eosin per litre, and was used as a standard.—G. H. F.

Anthocyanins and anthocyanidins ; Production of ——. A. E. Everest. Proc. Roy. Soc., 1914, B, **87**, 444—452, and **88**, 326—332. (See also this J., 1914, 18.)

Although quercitrin gave only anthocyanidin by reduction with zinc and acetic acid in the cold, yet the yellow glucosides of the flavonol class obtained from the yellow wallflower, yellow daffodil, crocus, tulip, jasmine, primrose, etc., yielded directly anthocyanins (glucosidal) without any intermediate production of anthocyanidins (non-glucosides). Provided the reduction was not carried too far no subsequent oxidation was in any case necessary for the production of the anthocyanin pigment. Contrary to the views of Willstätter the red pigments thus obtained by reduction are held to be identical with the natural anthocyanins, since they show a complete similarity of behaviour, being stable in acid solution, unstable in alkaline solution, decolorised by both oxidation and reduction, and also in neutral solution owing to isomerisation, the colour being reproduced on the addition of acids, with which they form red oxonium salts. The absorption spectra of the artificial and natural pigments are also similar.—G. F. M.

Colouring matters of Rhamnus catharticus. J. Oesch and A. G. Perkin. Chem. Soc. Trans., 1914, **105**, 2350—2357.

The colouring matters present in the berries of *Rhamnus catharticus* (Hungarian berries) are found to consist mainly of kaempferol, $C_{15}H_{10}O_6$, with a kaempferol methyl ether, $C_{16}H_{12}O_6$, and rhamnetin, $C_{16}H_{12}O_7$, and a small quantity of quercetin, $C_{15}H_{10}O_7$. The first three of these are believed to be identical with the colouring matters isolated from *Rhamnus catharticus* by Tschirch and Polacco (Arch. Pharm., 1900, **238**, 459) and described by them as rhamnolutin, $C_{15}H_{10}O_6$, rhamnocitrin, $C_{15}H_{10}O_5$, and β-rhamnocitrin, $C_{15}H_{10}O_5$. Krasowski (this J., 1909, 326) only succeeded in isolating rhamnetin and quercetin from these berries. Compared with Persian berries, the berries of *Rhamnus catharticus* gave much paler and duller shades on mordanted woollen cloth.—G. H. F.

British manufacture of aniline dyes. Manchester Guardian, Dec. 9, 1914. [T.R.]

Lord Moulton, at a meeting of representatives of the textile trades of Lancashire and Yorkshire, held at Manchester on December 8th, referred to the need for the manufacture of aniline dyes in this country.

England consumed £2,000,000 worth of dyes a year ; of this amount barely one-tenth was produced in this country. Stocks of dyes were rapidly diminishing, and practically Switzerland was the only nation from whom we could expect help, but Germany was threatening—and carrying out the threat—to stop all the supplies of intermediate products unless the Swiss manufacturers undertook not to export any of the dyestuffs to this country. Some English firms were manufacturing successfully, but their productions were altogether inadequate.

Assuming that the war was brought to a successful issue for the Allies in a political and military sense, the position, in his opinion, would not be equally favourable from an industrial point of view. They knew how the two dye trade rings in Germany, while competing at home, worked together against the foreigner. If peace were declared at this moment, the English textile industry would be so much under the domination of the German dye-producing industry that it could boycott it and overcharge it in the supply of dyes and it could hamper the industry pending the time when it could challenge its very existence. The contemplation of such a prospect made him feel that it was his business to sound a warning against the idea that this trouble was only temporary. The danger threatened more in peace than in war.

The sole cause of England's falling-back and Germany's progress in this great industry was that the Germans were perfectly prepared to undertake the intellectual study necessary to master a new science. The English could do it just as well ; in their great works there were English chemists fully as efficient as the Germans. But unfortunately the holders of capital in England had had little sympathy with knowledge that they did not themselves possess. The consequence had been that great inventions had fallen dead in England. They had been offered in Germany, and accepted, and the consequence had been great industrial production. Because the masters, the capitalists, had no sympathy with this self-preparation for a difficult task, there was no career for the young men who were willing to study. They were paid salaries quite insufficient for the training they had gone through ; that was why we were so poorly represented in the industrial ranks by chemists. As regards natural possessions, we were as well placed as Germany. The one thing was the difference in the human element ; it was not in intellectual capacity, but in the industry and the willingness to study to the bottom the subject which was in hand. We should not get a chemical industry like the Germans unless we trained ourselves for it, had faith in it, and embarked our capital in it.

Many objections had been urged against the scheme for the manufacture of dyes in this country. To the objection that there was a lack of technical skill, he had difficulty in returning a polite answer, for we had the command of abundant technical skill to create an industry. The processes were mostly well known, although a practised man might get a better yield of a particular product. The whole of the dyes of the class to which he referred, could certainly be produced in this country if proper plant and direction were provided.

It had been objected that it was impossible to compete with the German producers, but even in Germany individual firms were able to compete against the combines and maintain a profitable export business ; there were also some firms in this country : that proved that competition in production was not impossible. If manufacture took place on an economical unit—that was, on a scale which was adequately great—the advantages from production on an enormous scale were very small in comparison. Certainly England, with its great demand for dyes—and much of its demand was limited to comparatively few dyes—could start an industry which could challenge if not equal the economy of the biggest works.

Another objection had been that if the scheme were carried out, consumers might be supplied with dyes at less than cost price. He did not think that would happen, because if the Germans invaded the English market, the English producer would be able to retaliate by invading the Eastern markets where the Germans derived the profits which enabled them to attack the English industry.

There must be a great national effort to create a company, working under the conditions of other companies, suffering from its blunders, and profiting by its wisdom, but there were three conditions to be satisfied, or it would be a failure. The first condition was that it must be large, and, therefore, independent and beyond attack. It must also be national in the sense that it will be removed for ever from the temptation of listening to the voice of the charmer inviting it to enter a combine. The company must be not only powerful but one the loyalty of which was necessarily beyond all doubt, and that could only be got by Government assistance on such terms that the Government could stop it ever entering the backward path which would ruin its national unity. It must also be co-operative. The producer must be the consumer, and they would never link up all those industries unless those who used the dyes were interested in the production and therefore supplied a preferential market.

If a company were formed under those conditions it would be assured a long and successful existence, but if any one of the three essentials was omitted, it was predoomed to failure.

In reply to a question, Lord Moulton expressed a hope that associated industries would rise round this company to produce the raw materials, the manufacture of which was more akin to the heavy chemical trade than to the dye trade. He therefore thought that this work would fall into the hands of other industries, and that it would be to the benefit of all.

A resolution was carried unanimously approving a national effort on the general lines laid down by the Government.

British dye industry. Times, Dec. 23, 1914.

A CIRCULAR issued on Dec. 22nd by the Board of Trade Committee on Aniline Dyes, states that at a meeting of representatives of important firms and associations making use of artificial dyes, held on Tuesday, Nov. 10th, a Committee was appointed as representing the trades concerned, with authority to confer with the representatives of the Board of Trade with a view to the elaboration of a scheme on the lines of the memorandum submitted. The committee appointed was:—Mr. Lennox Lee (Calico Printers' Association, Ltd.), Mr. Milton S. Sharp (Bradford Dyers' Association, Ltd.), Mr. H. W. Christie (United Turkey Red Company, Ltd.), Mr. Chas. Diamond (English Sewing Cotton Company, Ltd.), Mr. G. Marchetti (John Crossley and Sons, Ltd.), Mr. R. D. Pullar (J. Pullar and Sons, Ltd.). This committee has been engaged upon the elaboration of the scheme already referred to, which involves the formation of a joint stock company having for its object the manufacture and supply of synthetic colours. The Government are prepared to assist such an effort on the following lines:—A limited company to be formed under the Companies Acts with a share capital of £3,000,000, divided into 3,000,000 shares of £1 each. The Government to advance to such company £1,500,000, bearing interest at the rate of 4% per annum and secured as a first charge on the assets and undertaking of the company, and be repayable in 25 years. The company shall remain British.

It is proposed to take over certain existing colour works and use the plants to their full capacity for the manufacture of such dyes as are essential. Arrangements have been made with Read Holliday and Sons, Ltd., for the extension of their plant to increase their output, and it is proposed that the new company shall take over the business and undertaking of Read Holliday and Sons, under an option which has been obtained. It is intended to negotiate for the acquisition of other businesses in the same way, and also to take steps to acquire a suitable site and erect works thereon. The Committee also hope that it will be possible to make arrangements on co-operative lines with existing concerns in Switzerland.

New interest in natural indigo. Oil, Paint and Drug Rep., Nov. 30, 1914. [T.R.]

THE crippling of the synthetic indigo industry has been turned to account by the British and Indian trade press as an occasion to revive interest in the restoration of natural production. The movement to break the German synthetic monopoly was started in London two years ago, but despite all efforts the vegetable dye failed to gain headway. Many dyers and consumers would now lend their support to the restoration of the natural industry, but the crop season is now so advanced that arrangements to secure an increased outturn in the near future cannot be made. Latest advices from Calcutta indicate that the area for the cultivation of indigo will prove about 20% less than that of last season. In 1895–6 exports reached their maximum at 187,337 cwt.; in 1902–3, a period following the establishment of the synthetic dye in Europe, the exports fell to 65,337 cwt.; while in 1912–13 they only reached 11,857 cwt. The United Kingdom has been most faithful among the principal consuming countries to retain the natural dye, although the country's requirements have been steadily curtailed.

Among the strongest merits of the artificial dye were the more uniform character of its effects and the easier methods of its operation. The percentage of indigotin in vegetable indigo had often proved difficult to determine. Wool takes more readily to the natural dye, but while the artificial does not yield quite so bright an effect, its colour is constant. To encourage the development of the natural industry, two proposals have been made: (1) to subsidise the industry in India, and (2) to restore the obligatory natural indigo clause in all government contracts. This clause is said to have been deleted under pressure of the German monopoly combined with representations on the part of English dyers. The indigo planters are urged to do their share for the industry by a more systematic method of cultivation of the best varieties, a better system of dye extraction and more rigid economy. References are made to the opportunities for the development of a British synthetic indigo industry, and laboratories of the United States are not likely to remain idle.

Report of Chemicals and Dyestuffs Committee to New York Section of Amer. Chem. Soc. *See* Trade Report.

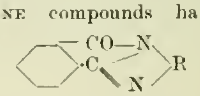
PATENTS.

Azo dyestuffs. H. Levinstein, J. Baddiley, and Levinstein, Ltd., Blackley. Eng. Pat. 25,547, Nov. 8, 1913.

THIS invention relates to dyestuffs of the general formula, $R.N_2.D.N_2.M.N_2.G.N_2.E$, where R represents the residue of resorcinol or *m*-aminophenol, D that of a *p*-diamine, M that of a middle component capable of further diazotisation after combination with a diazo compound, G that of 2-amino-8-naphthol-6-sulphonic acid, and E the residue of α-methylindole or a pyrazolone. They may be obtained by diazotising a monoacetyldiamine such as 4-acetamino-1-naphthylamine-6- or 7-sulphonic acid, combining with M, which may be 1-naphthylamine-6- or -7-sulphonic acid or a *m*-aminocresol ether, re-diazotising and combining with 2-amino-8-naphthol-6-sulphonic acid, diazotising and combining with the methylindole or pyrazolone, hydrolysing, again diazotising, and finally combining with resorcinol or *m*-aminophenol. Fast green shades are obtained by treating with formaldehyde fibres dyed with the products. —T. F. B.

Sulphur dyes. K. P. Grälert, M. Buff, and J. Flachslaender, Elberfeld, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pat. 1,112,445, Oct. 6, 1914. Date of appl., Dec. 6, 1913.

PHTHALOPERINONE compounds having the formula,



in which R represents a naphthalene nucleus, are treated with alkali polysulphides and copper or copper compounds. The products dye cotton brown shades, fast to light. (Compare Ger. Pats. 253.239 and 253.934; this J., 1913, 16, 80.)—T. F. B.

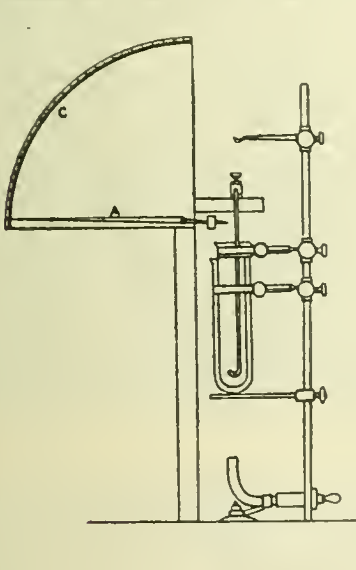
V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Artificial silks ; Damage caused by acid to —— and its prevention. P. Weyrich. Farber-Zeit., 1914, **25**, 114—118.

The damage known as "*Saurefrass*," caused by the presence of unstable sulphuric acid esters in artificial silks made by the collodion process (see this J., 1913, 80), is particularly troublesome in the case of silks dyed from baths of basic dyestuffs containing acetic acid. The sulphuric esters are extremely sensitive to hydrolysis by hot dilute acids, even acetic acid, with formation of free sulphuric acid. This migrates during drying to those parts where evaporation is most intense and becomes concentrated at those points. The damage may be prevented by drying the silk directly from a final bath containing 8—12% of a salt capable of combining with the free sulphuric acid, *e.g.* sodium acetate, lactate or formate, or borax. Dyed artificial silks finished in this manner will stand the stability test and can be heated to 140° C. without loss of strength or colour. It is desirable that the manufacturer of the silk should undertake the stabilisation of the goods before delivering them to the dyer. The unstable sulphuric esters may be decomposed by heating the silk impregnated with sodium acetate at 140° C., then washing and drying without heat.—J. F. B.

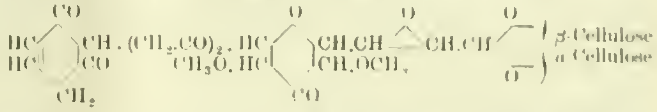
Textile fibres ; Swelling of —— on immersion in water. E. Justin-Mueller. Assoc. gén. des Chim. de l'Ind. Text., Paris, May, 1914. J. Soc. Dyers and Col., 1914, **30**, 354—355.

The author has devised "a turgometer" (see fig.) for measuring the degree of swelling, or "turgescence," of solid substances ("turgoids"), particularly organic substances, on immersion in water or aqueous solutions under certain conditions. Textile fibres are best examined in the form of threads ; whilst with woven material, threads of warp and weft are preferably examined separately, although narrow strips may be used. The thread is fastened at one end to a glass or metal rod and at the other to a movable lever, A, the longer arm of which indicates the degree of swelling on a graduated scale, C ; the larger portion (10 cm.) of the thread is immersed in the liquid. With cold liquids the pointer is adjusted to zero before the liquid is introduced, and the movement of the pointer is observed at intervals first of 1 min., then of 5 mins., and later of 10 mins., the temperature of the solution being also noted. When the behaviour in warm liquids is to be examined, the pointer is adjusted to zero immediately before warming. The method is useful for determining the most suitable concentration of caustic soda and time of immersion for mercerising cotton ; the critical temperature at which the fibre has the greatest turgescence—a point frequently of importance in dyeing ; and the determination of the degree of bleaching of vegetable fibres and detection of certain faults which occur in manufacture. In the case of cotton in caustic soda solution, the pointer rises to a certain height in a shorter time the less pure is the sample. A. S.



Cellulose and lignocellulose. C. F. Cross. J. Soc. Dyers and Col., 1914, **30**, 346—351.

The lignocellulose complex is composed of two or more celluloses in union with a lignone complex, the constituent groups of which may be represented by the general schematic formula :



$$\begin{array}{llll} \mathrm{CO} & \mathrm{O} & \mathrm{O} & \mathrm{O} \\ \mathrm{HC}\diagup\;\diagdown\mathrm{CH}.(\mathrm{CH_2.CO})_2.\mathrm{HC}\diagup & \diagdown\mathrm{CH.CH}\wedge & \mathrm{CH.CH}\diagup & \Big\}\ \beta\text{-Cellulose} \\ \mathrm{HC}\;|\quad|\;\mathrm{CO}\qquad \mathrm{CH_3O.HC}\;| & |\;\mathrm{CH.OCH_3} & & \mathrm{O}\ \Big\}\ \alpha\text{-Cellulose} \\ \mathrm{CH_2} & \mathrm{CO} & & \end{array}$$

The lignone and cellulose preserve their relationship unaltered through such reactions as hydration and hydrolysis, in which both complexes are equally attacked, and esterification, in which only the OH groups of the cellulose are directly involved. Attention is called to the specific colour reactions of lignocelluloses with aniline salts, diamine bases, and phloroglucinol (see this J., 1899, 616 ; 1907, 941, 942) and with ferric ferricyanide (this J., 1893, 104) ; of these there is some evidence that the former may be due to hydroxyfurfural formed from and within the lignone complex ; they are not given by lignocellulose which has been subjected to prolonged digestion with highly diluted sulphurous acid. It has been shown previously (this J., 1908, 802 ; also Eng. Pat. 5016 and Fr. Pat. 383,064 of 1907 ; this J., 1908, 330) that the lower acetates of cotton cellulose resist dyeing with substantive dyestuffs. Tests by H. Lyster Jameson have now demonstrated that whilst all other known textiles—in their natural condition, bleached, or treated by various methods—were completely disintegrated after periods varying from a few days to 6 weeks when immersed in sea water under natural conditions, acetylated cotton (monoacetate) was unchanged externally, had retained its strength, and had not lost weight, even after immersion for 8 months. The acetylated cotton is generally prepared in the form of yarn but can also be produced in the form of cloth.—A. S.

Pulp industry ; Progress in chemical ——. A. Klein. Papierfabrikant, 1914, 22, 601—603, 634—636.

The majority of the materials used for paper-making in Germany are derived from wood and straw, only about 5% of rags being employed. In Europe fir, spruce, pine, and larch woods are principally used, together with some poplar and beech. Formerly the losses amounted to 20% from peeling and boring out branches, with 15% due to sawing into discs, 3 cm. thick ; these losses are now reduced to 5—6% by hand-peeling and 10—12% by mechanical peeling. Formerly only 22—35% yields of pulp were obtained ; the sulphite process now yields 45—48%, the sulphate process 35—38%, and the soda process 30—38%. By increasing the pressure in the digesters the time required in the sulphite process has been reduced from about 36—48 hrs. to 9—10 hrs., while the use of mechanical stamps to ram the material in the digesters has increased the capacity to 85—95 kilos. per cb. metre. Vertical digesters have replaced the earlier horizontal type with improvement in speed of filling. Sulphite liquors containing large amounts of free acid are employed ; and the incidental sulphuric acid is reduced by thorough cooling of the gases and absorption surfaces ; the injurious effects of selenium in the pyrites used is almost wholly avoided by preventing formation of dust in roasting. Mechanical pyrites roasting furnaces are employed and rotary instead of stationary sulphur furnaces. The tower system of liquor preparation is now used more frequently than the tank system. By the recovery of waste gases and by reducing losses of gas and fibre the consumption of sulphur has been decreased considerably; formerly 100 kilos. of unbleached pulp required 45—90 kilos. of pyrites or 18—20 kilos. of sulphur: at the present time 25—26 kilos. of pyrites or 10—11 kilos. of sulphur suffice.

The older soda process using 5—5½% caustic soda solutions has been largely displaced by the sulphate process. This process uses liquors such as the following: 1·5% Na$_2$CO$_3$, 6·2% NaOH; 2·2% Na$_2$S, 0·3% Na$_2$SO$_3$; pressures up to 8 atm. being employed. The introduction of improved machinery and processes have led to the recovery of up to 90% of the soda instead of 58% as in former times. Of the numerous proposals for the utilisation of waste liquors for the manufacture of *e.g.* tanning materials, fertilisers, feeding stuffs, dyes, alcohol, etc., the author states that none have given practical results; the most promising are the processes devised for alcohol production (see this J., 1910, 810, 1052, 1265). Strehlenert's process (this J., 1913, 652) seems to be practicable, in this the sulphite liquor yields alcohol, plaster of Paris, sulphur dioxide and a fuel with a calorific value of 7000 cals. By Rinmann's process (see this J., 1914, 307) 500 kilos. of "carbon," 100 kilos. of spirit and acetone and 100 kilos. of motor spirit are said to be recovered per ton of cellulose.

Bleaching of pulp is carried out by means of hypochlorites, or by electrolytic chlorine; formerly 100 kilos. of pulp required 30—35 kilos. of bleaching powder, 10% or less now suffices with a loss of only 4—9% of fibre. Attention is called to the possibility of utilising such materials as broom rice and flax straw, bamboo, Savannah grass, maize stalks, etc.—R. G. P.

Mechanical pulp ; The grinding of spruce for ——. J. H. Thickens. U.S. Dept. of Forests Bull.; Papierfab. 1914, **12**, 275—281.

THE results previously reported (this J., 1913, 132) are republished with fuller details and additional matter. The coefficient of friction between the stone and the wood varies according to the nature of the wood, being lower for steamed than for raw wood; it decreases gradually as the pressure of grinding is raised. In industrial practice the wood is nearly always seasoned for a long period before grinding, but in addition to appreciable loss by rotting the pulp prepared from seasoned wood is shorter in fibre than that from green wood; steaming the wood before grinding gives longer fibres and stronger pulps but darkens the colour. At low pressures of grinding the consumption of power per ton of pulp is higher for seasoned than for steamed wood, while at high pressures the reverse is the case. For green wood the power-consumption per ton is lower than for either seasoned or steamed wood. The power supplied to the grinder under like conditions of speed and pressure is the same for green as for seasoned wood, but it is less for steamed wood. The rate of production of pulp from green wood is more rapid than from seasoned or steamed wood. The yield of pulp per 100 cub. ft. of solid wood of various species is directly proportional to the dry weight per cub. ft. It is approximately the same for seasoned as for green wood, but if taken on the basis of a cord of rough wood, there is probably more loss with seasoned wood owing to decay. The yield of pulp from steamed wood is considerably lower, owing to decomposition and solvent action, and it falls as the severity of the treatment is increased. The quality of the pulp is not greatly influenced by the moisture in the wood or the weight per cub. ft. With wood of rapid growth the yield per 100 cub. ft. is lower and the pulp is softer than with slow-grown wood but the strength is practically the same. Some valuable manufacturing data are obtained by comparing the power consumption per ton per unit of strength: the efficiency in this respect reaches a maximum and then decreases. The yield of pulp from trimmed wood is 88% by weight; the balance lost is divided between the screenings (2—7%) and the waste waters (5—10%) including both soluble and insoluble matters.—J. F. B.

Sulphite cellulose ; Resin in ——. Papierfab., 1914, **12**, 282.

TROUBLES due to the separation of the resin on the fibres in the digester were found to be more frequent in winter than in summer and were avoided by washing the pulp with water at 10°—20° C. forced in from below upwards by a centrifugal pump. The rinsing from above downwards, which is also necessary, was performed with warm water at 40° C. collected by condensing the steam blown off from the digesters and utilising other sources of waste heat.—J. F. B.

Pulp chests and the regulation of pulp. G. Janata. Papierfab., 1914, **12**, 186—189, 219—221.

FOR general purposes when two pulp chests are provided for a paper machine each may have a capacity equivalent to one hour's working or may hold the contents of two beaters diluted to a concentration of 3% of dry pulp. An average capacity is 22 cb. m. In German paper-mills chests with horizontal shafts and semicircular bottoms are preferred to the vertical cylindrical type; the pulp should always enter at the end opposite the outlet. The stirring is performed by two spiral bars connected by arms to the main shaft with a clearance of 5—10 cm. from the walls of the chest. The shaft is journaled outside the chest and passes through stuffing-boxes in the ends; it is driven by worm-gearing at a speed of 5—10 revs. per min. If the chest is placed at a low level, the stuff must be withdrawn by a pump discharging into a feed-box to the machine with an overflow back to the chest. Bucket-wheels are more common than pumps and require less attention; these are attached to the stirrer shaft and empty the pulp into a feed-box situated in the chest at a level from which it can run on to the machine. If the chest is placed sufficiently high the buckets can be designed to lift an excess of pulp and an overflow be provided back to the chest; generally, however, the scoops are arranged without an overflow. Pumps have the advantage that the quantity of dry pulp fed to the machine is less affected by variations in the concentration and height of the stuff in the chest than the older type of bucket-wheel. These advantages, however, may be obtained also with bucket-wheels by working with an overflow, as indicated, and by fitting Steinbock's buckets in which the quantity lifted is automatically kept constant whatever the height of the stuff until the latter falls below the level of the recess in which the buckets dip. In any form of chest, regular working can only be ensured by maintaining a steady concentration of the stuff; for this purpose an automatic measuring tank for the water employed to wash down the beaters is very useful. Feed-boxes with overflow are provided with a sensitive regulating valve for passing the stuff to the machine; an independent, quickly-closing sluice should be provided for stopping the flow without interfering with the adjustment of the valve.—J. F. B.

Oxford India-paper. Papierfabrikant, 1914, **22**, 605—606.

THIS paper, formerly made only in England, is now made in other countries; it must be as thin as possible, weighing under 30 grms. per sq. metre, non-transparent, and very resistant to ink penetration. It is made principally from linen rags, a "standard receipt" being 80% of best bleached white linen; 10% of best white bleached cotton; 5% of bleached straw pulp; 2% of finest white loading (*e.g.*, talc); 3% of waste. The rags are boiled with 1—2% of soda for 3 hrs. at 3 atm. pressure, washed carefully and bleached with 1—2% of chlorine until snow-white. Ultramarine is used for colouring and Indanthrene Blue R.S. for tinting. Beating is carried on for 20—34 hrs. in engines of up to 100 kilos. capacity, with sharp blades so as to obtain a short non-transparent whole stuff. Cone engines have proved very suitable; sand traps must be used on pulping and beating machines. Paper machines of 150—170 cm. width are most satisfactory;

running at not more than 40 metres per min. ; wire about No. 90. The strainers should be first a rotary strainer followed by a flat one, having slots 0·4 mm. wide and fitted with an automatic cleaning device. Shaking should be severe and short. Suction should be weak and couchers and presses lightly loaded so that the paper may have a thick handle. Stone rollers should be employed for the wet-press. The paper must be lightly calendered ; moist calendering is not used.—R. G. P.

[Paper.] Sizing ; Detection of rosin and animal ——. Kollmann. Papierfabrikant, 1914, **22**, 371—372.

Of the numerous proposed tests the author considers that Raspail's and the tannin tests are the only ones useful for rosin and animal sizing respectively. *Raspail's test for rosin.*—The paper is moistened on a microscope slide with concentrated sucrose solution, the fibres are teazed out and the excess of liquid removed by blotting paper ; on applying concentrated sulphuric acid a distinct red colour indicates rosin sizing. *Tannin test for animal sizing.*—The paper is warmed on a microscope slide with water, the paper is then removed and tannin solution added to the extract ; a brownish amorphous precipitate indicates animal sizing. Both tests should be applied only in absence of casein or fat.—R. G. P.

Kapok and akon, and the bitter principles, wax and resin contained therein. Matthes and Streicher. *See* XII.

Patents.

Cloth ; Process of preparing —— for testing its resistance to wearing. A. Kertesz, Mainkur, Germany. U.S. Pat. 1,116,077, Nov. 3, 1914 ; date of appl., March 14, 1914.

The material is prepared by wetting and pressing, boiling, treating with alcoholic, hydrocarbon or ethereal liquids and raising and pressing.—J. F. B.

Vegetable fibres ; Process of preparing ——. G. D. Burton, Assignor to The Burton Co., Boston, Mass. U.S. Pats. (A) 1,115,500 and (B) 1,116,343, Nov. 3, 1914 ; dates of appl., April 6, 1914 and March 27, 1913.

(A) Degummed fibrous material is treated with an oily substance in the form of minute particles in presence of an acid, or is immersed in a liquid carrier containing an acid and minute oily particles in suspension. The liquid may be produced by partially saponifying an oily substance with an alkaline saponifying agent and adding thereto a vegetable acid. (B) The oily substance in the form of minute particles is applied without the addition of an acid, and if used in the form of an emulsion the latter may be made by partial saponification by means of a weak volatile saponifying agent.—J. F. B.

VI.—BLEACHING ; DYEING ; PRINTING ; FINISHING.

Bleaching of wool fibre. A. F. Musgrave. Textile Colorist, 1914, **36**, 337—338.

Oxidising agents, as sodium and hydrogen peroxide, totally destroy the natural colouring matter of wool, while reducing agents, as sulphur dioxide, reduce the colouring matter, which is slowly oxidised back to its original colour in air. Hence in practice a double bleach is used, first with peroxide and then with sulphur dioxide. Sodium peroxide is superior to hydrogen peroxide in that it is less bulky and owing to its greater stability, is less dangerous to store, but in the labour involved in making up the bleach baths the advantage lies with hydrogen peroxide. By adding soap to the bleach bath it is possible to scour and bleach at the same time.—G. H. F.

Silk hank dyeing ; Hydrolytic dissociation assisted by air and light (photolysis) in relation to ——. E. O. Sommerhoff. Färber-Zeit., 1914, **25**, 171—173.

Hydrolytic dissociation plays an important part in many operations of the silk-dyeing industry. Dissociation is considerably intensified by the application of heat, and the similar influence of air and light has been recognised in practice by the custom of working the yarn in and out of the liquor. Two special instances of this type of reaction are quoted : (1) The method of degumming raw silk in a soap-and-air lather instead of in the liquid bath enables the process to be completed in a shorter time and with less expenditure of soap. The influence of the air and light increases the activity of the hydrogen ions of the water, intensifying the hydrolysis of the sodium-fatty acid salt and consequently the efficiency of the soap bath. In the exposure of soaped goods to the action of air and sunlight in laundry work, reactions of a similar order play a part. (2) The washing of silk treated with stannic chloride in a machine provided with revolving rollers is another instance of hydrolysis. The cold water quickly decomposes the stannic chloride into oxychloride and hydroxide ; in a short time no more hydrochloric acid can be detected with methyl orange. If the washed silk be then exposed to air and light a further quantity of hydrochloric acid makes its appearance owing to the further hydrolysis of the oxychloride. Hence it is advantageous not to wash continuously but to stop the machine from time to time to expose the goods.—J. F. B.

Vat-dyestuffs ; The action of "solution salt" on ——. Haller. Färber-Zeit., 1914, **25**, 8—10, 26—29.

Lichtenstein (this J., 1913, 134) regards the action of sodium benzylsulphanilate ("solution salt") on vat dyestuffs as being comparable with that of the protective colloids such as sodium protalbinate. The author, while confirming Lichtenstein's capillarity results, concludes from ultramicroscopic observations that their action is quite different. "Solution salt" greatly increases the degree of dispersion of the colloidal micellæ of Hydron Blue and its leuco derivative but sodium protalbinate has the reverse effect and gives a turbid dye-vat. Hydron Blue when suspended in water shows a large proportion of coarse particles and a few micellæ ; reduction by hydrosulphite slightly increases the degree of dispersion and the addition of sodium carbonate very considerably increases it. In practice, in order to obtain the maximum deflocculation of the coarse particles of dyestuff, it is therefore advantageous to add the "solution salt" and dyestuff together to the water, then the alkali and finally the hydrosulphite. A reduced dye-vat is not a solution of the sodium salt of the leuco compound but is still a colloidal solution and the dyeing results, as regards intensity, are directly proportional to the degree of dispersion of the micellæ. Thus with equivalent dye-vats, the vat containing "solution salt" gave the deepest shade on cotton, the ordinary vat gave lighter shades, while the vat containing sodium protalbinate, owing to the suppression of adsorption phenomena, gave very pale dyeings. Sodium chloride acts as a typical electrolyte causing aggregation of the micellæ. The action of "solution salt" is quite specific : it has an effect the reverse of that of an electrolyte, but on the other hand it does not act as a protective colloid, since the baths containing it, unlike those to which sodium protalbinate has been added, are still sensitive to dilute solutions of electrolytes. Its action is physical and not chemical, since the whole of the "solution salt" may be removed unchanged from the bath by dialysis.—J. F. B.

Naphthol AS and its use in calico printing. A. Lomanowitsch. Färber-Zeit., 1914, **25**, 175—177.

Naphthol AS is the anilide of 2.3-hydroxynaphthoic acid which when developed on cotton with certain diazo salts gives very bright and fast colours. For printing, the cloth is padded with a solution of Naphthol AS in caustic soda, with castor oil soap and sodium acetate. The goods are dried and printed : for blue, with thickened diazotised dianisidine; for red, with diazotised *p*-nitro-*o*-toluidine. The addition of aluminium sulphate to the diazo solution is necessary but the use of copper chloride, recommended by the makers, is considered to be injurious. The colours obtained are superior to those produced with *β*-naphthol and faster to steaming: a mixture of the two naphthols may sometimes be used to modify the shade. The whites of the printed cloth are difficult to clear in the ordinary way, but if a little caustic soda be added to the soaping bath at 62° C. the clearing is satisfactory; if other colours are also present, dyestuffs fast to caustic soda must be employed. For dyeing piece goods, Naphthol AS, developed with diazotised dianisidine with aluminium acetate, gives full indigo blue shades. A printed discharge is obtained on these by means of hydrosulphite NF and anthraquinone, but the discharge is more difficult than on *β*-naphthol colours. The goods must be strongly steamed for at least 5 minutes and the white cleared in alkaline soap solution followed by bleach liquor. White and coloured reserve effects are obtained by printing on the Naphthol AS ground with tin salt mixture containing basic dyestuffs if desired, drying and then developing with the diazo solution. Yarn treated with a mixture of Naphthol AS and formaldehyde may be dyed with diazo salts without intermediate drying.—J. F. B.

Swelling of textile fibres on immersion in water. Justin-Mueller. *See* V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Acids; Exportation of —— from Italy. L'Ind. Chim., Min. e Met., 1914, **1**, 449. (See also this J., 1914, 897.)

In reply to a petition of the Turin Chamber of Commerce the Italian Minister of Finance has stated that it may be possible to allow definite quantities of sulphuric and hydrochloric acids to be exported after consideration of the circumstances in each instance.—C. A. M.

Potash salts. Summary for 1913. Compiled by W. C. Phalen, U.S. Geol. Survey. Chem. Eng., **20**, [3]. Chem. News, 1914, **110**, 219—221, 231—233, 241—244, 251—252, 261—262.

The saline potash deposits of California, Oklahoma, and Texas were examined, and it is estimated that at Searles Lake, Cal., potassium compounds, equivalent to 6,000,000 tons of chloride, are available. A process has been devised by Chappell (this J., 1913, 910) for obtaining potassium sulphate and alumina from alunite which is widely distributed in certain of the Western States, and attention is drawn to the fertilising value of this mineral, whether raw or roasted, and also of the kelp found along the Pacific coast (see also Skinner and Jackson, this J., 1913, 618). Further investigations on kelp were made, and several companies formed for making potash and fertiliser from this source (see this J., 1912, 227, 1177: 1914, 1086). Processes for the extraction of potash salts from silicate rocks (this J., 1913, 487, 699, 977) are reviewed, and one process (this J., 1911, 955) is said to be in experimental operation. The shipments of potash salts and potash fertilisers, in metric tons, from the German potash mines, for native and foreign consumption, during 1911 and 1912, were:—

(a) Not separately classified. (b) From August 5 to December 31.

—F. Sodn.

Salts which contain two solvents of crystallisation ; A class of ——. J. E. Marsh. Chem. Soc. Trans., 1914, **105**, 2368—2370.

Crystals of $KHgI_3,H_2O,3(CH_3)_2CO_3$ were obtained by cooling a solution of potassium and mercuric iodides (molecular proportions) and water in hot methyl carbonate and by crystallising $KHgI_3,H_2O$ from the same solvent. The salt, $NH_4HgI_3,H_2O,2(CH_3)_2CO_3$ was similarly prepared, and $RbHgI_3,H_2O,2(CH_3)_2CO_3$, by adding $RbHgI_3,H_2O$ to methyl carbonate. Molecular proportions of silver iodide and sodium or potassium iodide, dissolved in a mixture of methyl carbonate and water, yielded crystals of $NaI,AgI,2H_2O,2(CH_3)_2CO_3$ or $KI,AgI,H_2O,(CH_3)_2CO_3$.—F. Sodn.

Ferrous chloride and nitric oxide ; A supposed crystalline compound of ——. I. Bellucci. Gaz. chim. ital., 1914 **44**, II., 384—389.

Thomas (Bull. Soc. Chim., 1895, [3], **13**, 385) claimed to have obtained a crystalline compound, $FeCl_2,NO,2H_2O$, by the action of nitric oxide on a saturated ethereal solution of ferric chloride. The author finds that dry nitric oxide has no action on a solution of anhydrous ferric chloride in anhydrous ether, if moisture be excluded. In presence of water reaction occurs: the solution becomes dark green and a small quantity of nitric acid is formed. If the solution be evaporated *in vacuo* over sulphuric acid, the original yellow colour is restored, and a yellow microcrystalline residue is obtained as described by Thomas. This consists, however, not of the compound described by him, but of ferric chloride together with a small quantity of nitric acid. (See also Manchot, this J., 1914, 642, 643.)

—A. S.

Metals ; Displacement of — *from aqueous solutions of their salts, by hydrogen at high temperature and pressure.* W. N. Ipatieff and A. K. Starynkevitch. J. Russ. Phys.-Chem. Soc., 1914, **46**, 172 173. Bull. Soc. Chim., 1914, **16**, 753.

From a saturated solution of mercurous nitrate, hydrogen under a pressure of 130 atmospheres caused the deposition of bright yellow crystals of $2HgO,N_2O_5,H_2O$ (in which globules of mercury were visible under the microscope) at 160° C., and metallic mercury alone at 225° C., the solution becoming acid in the latter case: from a solution of mercuric nitrate with hydrogen at 120 atm., crystals, similar to the above but mixed with HgO, were obtained at 110° C., and metallic mercury, with crystals of HgO, at 240°—250° C., the latter solution also becoming acid. At 220° C. with hydrogen at 195 atm., white needles of $Cd(NO_3)_2,CdO,2H_2O$ were deposited from a 2*N*-solution of cadmium nitrate, the deposit obtained at 250°—260° C. with hydrogen at 220 atm. being similar but containing crystals of cadmium. From a 2*N*-solution of cadmium sulphate with hydrogen at 250 atm., $CdSO_4,H_2O$ and occasionally cadmium were obtained at 220° C., and yellow needles of CdS at 270°—285° C. A basic salt was deposited from a 2*N*-solution of zinc nitrate at 290° C. by hydrogen at 140 atm., and crystals of ZnO at 320°—330° C.: the deposit obtained at 350° C. with hydrogen at 360—380 atm. was similar to the preceding but contained microscopic crystals of zinc. Crystals of ZnS were deposited from a 2*N*-solution of zinc sulphate at 290° C. by hydrogen at 250 atm. From a 2*N*-solution of magnesium nitrate crystals of MgO were deposited at 340° C. by hydrogen at 230 atm.; while a basic solution of MgS was obtained from a 2*N*-solution of magnesium sulphate at 340° C. with hydrogen at 340 atm. Heated in a quartz tube, a 2*N*-solution of nitric acid was completely converted into NH_3 at 370° C. by hydrogen at 300 atm., while a similar solution of sulphuric acid was almost completely decomposed into H_2S at 350° C. by hydrogen at 238 atm. In the presence of water, freshly precipitated zinc oxide was not reduced at 380° C. by hydrogen at 320 atm.—W. E. F. P.

Nitric oxide and chlorine; Rate of combination of gaseous ——. I. J. E. Coates and A. Finney. Chem. Soc. Trans., 1914, **105**, 2444—2452.

Nitric oxide and chlorine were allowed to mix in equivalent proportions and the rate of decrease of pressure, at constant volume, was observed. Velocity constants, calculated from the results obtained at 0° and 14·8° C., indicate a reaction of the third order, as required by the equation $2NO + Cl_2 = 2\ NOCl$. The temperature-coefficient was approximately 1·23 for an increase of 10° C.—F. Sodn.

Nitrogen trioxide; Dissociation of gaseous ——. B. M. Jones. Chem. Soc. Trans., 1914, **105**, 2310—2322. (Compare H. B. and M. Baker, this J., 1907, 1276.)

The vapour density of a sample of nitrogen trioxide, which had been dried for two years over phosphorus pentoxide, was determined at a series of temperatures, pressures, and volumes ranging from 15°—138° C., 106—818 mm., and 1·05—0·2 litres respectively. The results obtained (35·07 to 24·00) are in agreement with the assumption that the liquid is mainly in the form of N_4O_6 molecules, which increase in number on drying and are blue; a certain number of NO_2 (or N_2O_4) and NO molecules are also present, owing to incomplete drying. On vaporisation, the N_4O_6 molecules dissociate (almost completely at 140° C.) to give N_2O_3, NO_2, and NO in equal volumes (the reverse change taking place on cooling). Both N_4O_6 and N_2O_3 are colourless or nearly colourless in the gaseous state.—F. Sodn.

Cerium and hydrogen; Reciprocal action of ——. I. I. Joukoff. J. Russ. Phys.-Chem. Soc., 1914, **45**, 2073. Bull. Soc. Chim., 1914, **16**, 531.

Cerium when heated in an atmosphere of hydrogen rapidly absorbed the gas at about 350° C. Between 450° and 510° C. the dissociation pressure was about 1 mm. so long as the proportion of hydrogen did not exceed that corresponding to CeH_2; beyond this the dissociation pressure increased with the hydrogen concentration. It is concluded that the hydride, CeH_2, is formed, and that this hydride is capable of dissolving hydrogen.—A. S.

Sulphur and selenium; Preparation of colloidal solutions of —— in glycerol and erythritol and mixtures of the same. P. P. von Weimarn. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1689—1690. Bull. Soc. Chim., 1914, **16**, 180.

Solutions of sulphur or selenium in glycerol or erythritol when cooled to very low temperatures, *e.g.*—80° C., yielded colloids of varying degrees of dispersion according to the rate of cooling and the concentration. When added to cold water, these products yielded colloidal solutions, those of sulphur being colourless and transparent, or more or less opalescent, and those of selenium being orange, red or pink. The solutions possess considerable stability: the orange selenium sol showed no perceptible change after 10 days. Above 160° C. the sulphur glycerinosols acquired a deep blue colour.—A. S.

Lead and the end product of thorium. Part I. A. Holmes and R. W. Lawson. Phil. Mag., 1914, **28**, 823—840.

It has been suggested recently that the end products of the disintegration of uranium, thorium, and actinium are all isotopic with (*i.e.* indistinguishable chemically from) ordinary lead. This view has been practically established so far as the end product of uranium (uranium lead or radium G) is concerned, the ratio Pb : U being constant in minerals of the same geological age and increasing with the age in the case of minerals of varying age. Analysis of a number of Devonian minerals and comparison of published analyses of minerals of varying geological age has now shown that there is no constancy in the Pb : Th ratios for minerals of the same age, and hence that thorium E (thorium lead) cannot be a stable isotope of lead, but must disintegrate slowly, losing radiations which have so far escaped detection (the half-period of decay has been calculated to be 6×10^5 years by R. W. Lawson, Nature, July 9, 1914). It is suggested that the stable end products of thorium and actinium are respectively bismuth and thallium.—A. S.

Thorium D; Volatility of ——. Note on the relative β-activities of thorium C and D. A. B. Wood. Phil. Mag., 1914, **28**, 808—818.

An active deposit of Th D, untreated, or treated with nitric acid, volatilised at 520° C., but at 270° C. after treatment with hydrochloric acid. This is in accord with the views of Schrader (this J., 1912, 685), Russell (this J., 1912, 685), and Barratt and Wood (Proc. Phys. Soc., London, June, 1914), that active deposits of radioactive substances are capable of forming definite chemical compounds. Th D recoils in the atomic state from Th C, whether the latter be free or combined with acids, but from thorium active deposit dissolved in hydrochloric acid, a portion of the recoiling atoms of Th D appears to recombine with chlorine liberated by the disintegration of molecules of thorium chloride.

Thorium D is completely volatilised above 700° C., whilst Th C volatilises only at about 780° C. This method was used to obtain Th C free from Th D, and pure Th D. The relative β-activities of the two products were found to be 1·5 : 1.—A. S.

Radium in India. [T.R.]

M. C. A. Crump, of Bombay, while on the Singar estate in the Gaya district, states that: The pitchblende mine on Abrakhi Pahar, a small hill situated about half a mile due east of the village of Bhanekhap, is now being worked. It is only 42 feet deep, as without aid of any mechanical contrivances progress is necessarily slow. Over 8 cwt. of pitchblende has been won, and there is every prospect of finding further segregations at a depth yielding a richer supply of the precious mineral. Outcrops of triplite (a ferrous manganous fluophosphate that seems to be associated with pitchblende) have been found in other parts of the estate. Both pitchblende and uranium ochre have been known for many years to occur in the Gaya district at the Singar mica mines, though very little has been done to ascertain the amount available.

Saltpetre in Texas. Oil, Paint, and Drug Rep. Nov. 23, 1914. [T.R.]

A supply of nitrate of potash is reported to have been discovered near Alpine, Texas. A company will be formed to place the product on the market.

Japan's drug and chemical trade. Oil, Paint and Drug Reporter, Nov. 23, 1914. [T.R.]

Since the beginning of September many large orders for chemicals and drugs have been received in Japan from Russia. These articles had formerly been obtained in Germany, and more recently from England and the United States. The demand for iodine compounds, acetic acid and other chemicals has been particularly large, and they are being exported from Kobe firms to Russia.

Hungarian chemical industry. Chem. and Druggist, Dec. 4, 1914. [T.R.]

Of all branches of Hungarian industry the chemical factories have suffered most from the war; 70 per cent. of the dye and general chemical manufactories have been stopped, the only exception being the mineral oil works, which are furnishing benzine for the army. The stocks of raw material for this industry, however, will soon be exhausted. Only three sugar factories are at work, the others being stopped because of lack of railway facilities for the conveyance of the beets. The glass industry is also seriously affected; only four of eighteen glass factories are at work, the others having had to stop on account of lack or raw material or of capital.

Patents.

Burner gases; Method of separating water from ——. J. B. F. Herreshoff, Assignor to General Chemical Co., New York. U.S. Pat. 1,113,437, Oct. 13, 1914; date of appl., Feb. 17, 1911.

Burner gases which have been treated with dilute sulphuric acid are rapidly cooled from 200° to 100° F. (93° to 38° C.) and the condensed liquid removed.
—F. Sodn.

Sulphuric acid; Apparatus for the concentration of ——. R. Bithell and J. A. Beck, Belfast. Eng. Pat. 25,526, Nov. 7, 1913.

A hollow column, heated internally, is provided on the outside with a number of superposed gutters through which the acid gravitates successively. The inner walls of the troughs are constituted by the column itself, whilst the outer walls, which are curved in vertical section, have each a cut to allow the overflow of acid into the trough immediately below. A valve regulates the flow of acid into the uppermost trough, and the bottom trough has a curved outlet. The column is constructed of iron or other material and may be built up in sections.—F. Sodn.

Sulphuric acid; Tray or dish for use in the concentration of —— [*by the cascade system*]. J. A. Beck, R. Bithell, and J. A. Beck and Son, Ltd., Belfast. Eng. Pat. 25,802, Nov. 11, 1913.

A shallow vessel, with a flange at its upper part, designed to rest upon the brickwork of the flue, so as to allow the body of the vessel to fit completely into the aperture provided, and thus expose a relatively extended surface to direct contact with the heating gases. (Reference is directed to Eng. Pats. 2205 of 1872 and 2839 of 1879.)
—F. Sodn.

Sulphuric acid; Tubular apparatus for treating corrosive liquids more especially for concentrating —— *by steam heat.* P. M. Pritchard and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 29,542, Dec. 22, 1913.

The joints between the protective coverings of the tubes and the lining of the evaporation vessel are so made that they are not subjected to the pressure of the fluid (*e.g.*, steam) passed through the tubes, and the joints of the tubes with the chests, for the inlet and outlet of the heating fluid, are so arranged as to be out of contact with the liquid under treatment. In apparatus for concentrating sulphuric acid, for example, the leaden lining of the evaporation vessel is turned in at each tube-plate hole, so as to form a seating against which the flanged end of a leaden sleeve, fitting over the tube-covering, is forced by means of a nut manipulated from the outside, and the ends of the sleeve and cover are burned together in a space provided between the tube-plate of the evaporation vessel and that of the steam-chest, whilst the ends of the tubes are expanded into nuts screwed into openings in the inner walls of the steam-chests. The tubes are readily removed and replaced.
—F. Sodn.

Ammonia still. W. H. Wright, Duluth, Minn. U.S. Pat. 1,114,843, Oct. 27, 1914; date of appl., Aug. 29, 1910.

A column comprises a series of superimposed rectangular segments, having weirs, and a lower series of segments each containing a number of parallel connected canals, formed by dams projecting alternately from opposite walls. The liquor is heated in the upper segments by ascending hot gases and then passes to the lower segments. Vapour "risers," with saddle-shaped seal bonnets, in the walls of the canals, allow heated vapours to pass through the liquor, which overflows from the canals, through removable ducts, to a lime-box and thence to the canals of a lower segment, means being arranged for the supply of steam to the lowest segment. The seal bonnets are adapted to slide longitudinally from the risers and to be removed by hand through openings in the walls.—F. Sodn.

Ammonia and alumina from aluminium nitride; Process of producing ——. E. Milde, Goldschmieden, Germany, Assignor to Aluminium Industrie Aktienges., Neuhausen, Switzerland. U.S. Pat. 1,115,003, Oct. 27, 1914; date of appl., June 10, 1913.

Aluminium nitride is converted by boiling with the hydroxide of an alkaline-earth metal into ammonia and an alkaline-earth aluminate, and the latter is boiled with a highly concentrated solution of alkali carbonate, the resulting alkali aluminate being treated for the production of pure alumina. Or, the nitride and alkaline-earth hydroxide are boiled simultaneously with the solution of alkali carbonate, and alumina prepared from the concentrated solution of alkali aluminate thus obtained.
—F. Sodn.

Cyanogen compounds; Process of preparing ——. J. E. Bucher, Coventry, Assignor to Nitrogen Products Co., Providence, R.I. U.S. Pat. 1,116,559, Nov. 10, 1914. Date of appl., March 9, 1914.

See Eng. Pat. 11,797 of 1913; this J., 1914, 749.—T. F. B.

VIII.—GLASS; CERAMICS.

Chemically resistant glass lacquer. Fox. *See* XIII.

Patents.

Glass-melting furnace. T. L. Holle, St. Louis, Mo. U.S. 1,111,258, Sept. 22, 1914. Date of appl., April 9, 1913.

In a furnace of the non-reversible regenerative type, burner and down-take flues are disposed alternately on each side of the furnace body, connecting this with a regenerator. Each burner flue and down-take flue on one side are opposite a down-take flue and a burner flue respectively on the other side of the furnace, whereby the products of combustion are drawn in several directions through the interior of the furnace and are equally distributed to the several outlet flues.—A. S.

Brick dryers; Gas furnace for ——. G. M. Raymond and G. R. Mumma, Assignors to C. W. Raymond Co., Dayton, Ohio. U.S. Pat. 1,117,905, Nov. 17, 1914; date of appl., June 18, 1914.

The front wall of the dryer has a pocket in the inner face with a burner tube mounted in it, and extending into the furnace. The communicating air passages extend longitudinally through the furnace, and connect the pocket with the atmosphere through the front wall and the chequer work mounted in the furnace on each side of the air passages.—G. W. McD.

Enamel; White ——. I. Kreidl, Vienna. U.S. Pat. 1,117,197, Nov. 17, 1914. Date of appl., Oct. 30, 1912.

See Fr. Pat. 450,228 of 1912; this J., 1913, 488.—T. F. B.

IX.—BUILDING MATERIALS.

Patent.

Manufacture of fuel and other briquettes and of briquette and other binders. Eng. Pat. 22,738. *See* IIa.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Specifications adopted by the American Society for Testing Materials, 1914; *Standard* ——. Year-Book of the Society, 1914.

Carbon-steel rails. Inspection.—Inspectors representing the purchaser shall have free entry to the works of the manufacturer at all times while the contract is being executed, and shall be afforded all reasonable facilities to ascertain that the rails have been made and loaded in accordance with the terms of the specification. All tests and inspections shall be made at the place of manufacture, prior to shipment, and shall be so conducted as not to interfere unnecessarily with the operations of the mill. *Material.*—The material shall be steel made by the Bessemer or open-hearth process, as provided by the contract. *Chemical requirements.*—The chemical composition of the steel from which the rails are rolled shall be within the following limits:—

	Weights, lb. per yd.			
	50–69 incl.	70–84 incl.	85–100 incl.	101–120 incl.
Bessemer steel.				
C%	0·37—0·47	0·40—0·50	0·45—0·55	0·45—0·55
Mn%	0·80—1·10	0·80—1·10	0·80—1·10	0·80—1·10
P% max. ..	0·10	0·10	0·10	0·10
Si% max. ..	0·20	0·20	0·20	0·20
Open-hearth steel.				
C%	0·50—0·63	0·53—0·66	0·62—0·75	0·62—0·75
Mn%	0·60—0·90	0·60—0·90	0·60—0·90	0·60—0·90
P% max. ..	0·04	0·04	0·04	0·04
Si% max. ..	0·20	0·20	0·20	0·20

Average carbon.—It is desired that the percentage of carbon in an entire order of rails shall average as high as the mean percentage between the upper and lower limits specified. *Analyses.*—Analyses shall be furnished as follows:—For the Bessemer process, the manufacturer shall furnish to the inspector, daily, determinations of carbon for each heat before the rails are shipped, and analyses of the average amount of the elements, C, Mn, Si, P, and S, for each day and night turn. These analyses shall be made on drillings taken from the ladle test ingot not less than ⅛ in. beneath the surface. For the open-hearth process the manufacturer shall furnish the inspector with a chemical analysis showing the amounts of the elements, C, Mn, Si, P, and S, for each heat. On request of the inspector, the manufacturer shall furnish a portion of the test ingot for check analysis. *Physical requirements.*—Tests shall be made to determine:—Ductility or toughness as opposed to brittleness; and soundness. The physical qualities shall be determined by the standard drop-testing machine of the American Railway Engineering Association. The tup shall weigh 2000 lb. and have a striking face with a radius of 5 in. The anvil block shall weigh 20,000 lb. and be supported on springs. The supports for the test pieces shall be a part of, or firmly secured to, the anvil, and shall be spaced 3 ft. between the centres for rails 100 lb. per yd. or less in weight and 4 ft. for rails over 100 lb. per yd. in weight. The bearing surfaces of the supports shall have a radius of 5 in. *Pieces for drop tests.*—Drop tests shall be made on pieces of rail not less than 4 ft. and not more than 6 ft. long. These test pieces shall be cut from the top end of the top rail of the ingot, and marked on the base or head with gauge marks 1 in. apart for 3 in. each side of the centre of the test piece, for measuring the ductility of the metal. *Temperature* of the test pieces to be between 60° and 100° F. (15·5°—38° C.). *Height of drop.*—The test piece shall ordinarily be placed head upwards on the supports.

Weight of rail. lb. per yd.	50—60	61—79	80—90	91—100	101—120
Height of drop. ft.	15	16	17	18	21

Under impacts, the rail under one or more blows shall show at least 6% elongation for one inch or 5% each for two consecutive inches of the 6 in. scale marked as described in the above section on "*Pieces for drop tests.*" A sufficient number of blows shall be given to determine the complete elongation of the test piece of at least every fifth heat of Bessemer steel, and of one out of every three test pieces of open-hearth steel. It is desired that the permanent set after one blow under the drop test shall not exceed that in the following table, and a record shall be made of the information:—

Section.	Weight, lb. per yd.	Moment of inertia.	Permanent set, inches (measured by middle ordinate in a length of 3 ft.).	
			Bessemer process.	Open-hearth process.
A.R.A.—A.	100	48·94	1·65	1·45
A.R.A.—B.	100	41·30	2·05	1·80
A.R.A.—A.	90	38·70	1·90	1·65
A.R.A.—B.	90	32·30	2·20	2·00
A.R.A.—A.	80	28·80	2·85	2·45
A.R.A.—B.	80	25·00	3·15	2·85
A.R.A.—A.	70	21·05	3·50	3·10
A.R.A.—B.	70	18·60	3·85	3·50

Test pieces which do not break under the first or subsequent blows shall be nicked and broken, to determine whether the interior metal is sound. One piece shall be tested from each heat of Bessemer steel.

Open-hearth steel girder and high tee rails:—The chemical composition shall conform to either of the following requirements:—

	Class A.	Class B.
C%	0·60—0·75	0·70—0·85
Mn%	0·60—0·90	0·60—0·90
Si%	not over 0·20	not over 0·20
P%	not over 0·04	not over 0·04

Analyses are to be made by the manufacturer from a test ingot taken during the pouring of each melt. *Drop tests* shall be made on a machine of the type recommended by the American Railway Engineering Association.

Low carbon steel splice bars.—The steel may be made by the Bessemer, open-hearth, or any other process approved by the purchaser. If made by the Bessemer process it shall contain not more than 0·10%, and by the open-hearth process not more than 0·05% P. The tensile strength shall be 55,000—65,000 lb. per sq. in. and the elongation, min., in 8 in., 25%.

Medium carbon steel splice bars.—The steel shall be made by the open-hearth process and shall contain: C not less than 0·3 and P not more than 0·04%. It shall have a tensile strength of 68,000 lb. per sq. in., and an elongation, in 2 in., equal to $\frac{1,000,000}{\text{tensile stress}}$ but in no case under 20%.

High carbon steel splice bars.—The steel shall be made by the open-hearth process, and contain: C not under 0·45%; P. not over 0·04%, minimum tensile strength, 85,000 lb. per sq. in., elongation in 2 in., 14%. *Bend tests.*—A specimen of ½ sq. in. section shall bend cold through 90 deg. around a pin the diameter of which is equal to three times the thickness of the specimen, without cracking on the outside of the bent portion. If preferred by the manufacturer and approved by the purchaser, the following bend test may be substituted for the above. A piece of the finished bar shall bend cold through 45 deg. around a pin the diameter of which is equal to three times the greatest thickness of the section, without cracking on the outside of the bent portion.

Extra high carbon steel splice bars.—Steel to be made by the open-hearth process and to contain not over 0·04% P. The minimum tensile strength to be 100,000 lb. per sq. in. and elongation in 2 in., 10%. A specimen of ½ sq. in. section to bend cold through 60° around a pin the diameter of which is equal to 3 times the thickness of the specimen, without cracking on the outside of the bent portion.

Structural steel for bridges.—Steel to be made by the open-hearth process and to conform to following requirements :—

	Structural steel.	Rivet steel.
Composition :		
P acid	not over 0·06%	not over 0·04%
P basic	not over 0·04%	not over 0·04%
S	not over 0·05%	not over 0·045%
Physical properties :		
Tensile strength, lb. per sq. in.	55,000—65,000	46,000—56,000
Yield point, min., lb. per sq. in.	0·5 tens. str.	0·5 tens. str.
Elongation in 8 in. min., %	$\frac{1,500,000}{\text{Tens. str.}}$	$\frac{1,500,000}{\text{Tens. str.}}$
Elongation in 2 in. min., %	22	—

Structural nickel steel.

Composition.	Structural steel.	Rivet steel.
C	not over 0·45%	not over 0·30%
Mn	not over 0·70%	not over 0·60%
P acid	not over 0·05%	not over 0·04%
P basic	not over 0·04%	not over 0·03%

Structural steel for buildings.

	Structural steel.	Rivet steel.
Composition :		
P Bessemer	not over 0·10%	
P Open-hearth	not over 0·06%	not over 0·06%
S	—	not over 0·045%
Physical properties :		
Tensile strength, lb. per sq. in.	55,000—65,000	46,000—56,000
Yield point, min., lb. per sq. in.	0·5 tens. str.	0·5 tens. str.
Elongation in 8 in., min., %	$\frac{1,400,000}{\text{Tens. str.}}$	$\frac{1,400,000}{\text{Tens. str.}}$
Elongation in 2 in. %	22	

Structural steel for locomotives.—P to be not over 0·05, and S not over 0·05%. Tensile strength, 55,000—65,000 lb. per sq. in. Minimum yield point 0·5 tens. str. Minimum elongation in 8 in., $\frac{1,500,000}{\text{Tens. str.}}$%.

Structural steel for cars.

Composition :	Structural steel and plates for cold flanging	Rivet steel
P acid	not over 0·06%	not over 0·04%
P basic	not over 0·04%	not over 0·04%
S	not over 0·05%	not over 0·045%
Physical properties.	**Structural steel.**	**Rivets, and plates for cold flanging**
Tensile strength, lb. per sq. in.	50,000—65,000	48,000—58,000
Yield point, min., lb. per sq. in.	0·5 tens. str	0·5 tens. str
Elongation in 8 in., min., %	$\frac{1,500,000}{\text{Tens. str}}$	$\frac{1,500,000}{\text{Tens. str}}$

Structural steel for ships.—Steel to be made by the open-hearth process and to be of the chemical composition specified above for structural steel for cars. Tensile strength to be 58,000—68,000 lb. per sq. in. Minimum yield point, 0·5 tens. str. Min. elongation in 8 in., $\frac{1,500,000}{\text{Tens. str.}}$%.

Rivet steel for ships.—S not to exceed 0·045%. The rivet shank shall bend cold through 180 deg. flat on itself without cracking on the outside of the bent portion, and the rivet head shall flatten, while hot, to a diameter 2½ times that of the shank without cracking at the edges. The chemical and physical requirements are otherwise as specified for structural steel for bridges.

Carbon-steel bars for railway springs.—The steel shall be made by the open-hearth, crucible, or electric process, and shall be of the following composition :—

	Class A.	Class B.
	Elliptical and helical springs.	Helical springs.
C, %	0·90—1·10	0·95—1·15
Mn, max %	0·50	0·50
P, max. %	0·05	0·05
S, max. %	0·05	0·05

Billet steel concrete reinforcement bars.—P not to exceed 0·10% in steel made by Bessemer process, and not above 0·05% in open-hearth steel. The bars shall be made from new billets. Cold twisted bars shall be twisted cold with one complete twist in a length not over 12 times the thickness of the bar. The requisite physical properties vary according to the different grades of plain, deformed, and cold-twisted bars.

Blooms, billets, and slabs for carbon steel forgings.—These are divided into 5 classes of varying carbon ranges according to the purpose to which the steel is to be applied. C ranges from 0·08 to 0·60 %. Mn from 0·30 to 0·70, P, max., 0·045, and S, max., 0·05%.

Carbon steel and alloy steel forgings. Small variations in the Mn and Ni content are allowed according to the particular application of the forgings. The lower limit of Mn varies from 0·30 to 0·40, and the higher limit from 0·55 to 0·80. P not over 0·04 to 0·05. S not above 0·05%. Ni, not under 3·00%.

Quenched and tempered carbon steel axles, shafts, and other forgings for locomotives and cars.—C, lower limit 0·25—0·35%, higher limit 0·60—0·70%, in each case according to classification : Mn 0·40—0·70, P not over 0·05, and S not over 0·05%.

Carbon steel forgings for locomotives.—Mn 0·40—0·70%. P not over 0·05%. S not over 0·05%.

Carbon steel car and tender axles.—C 0·35—0·55%. Mn not over 0·70, P not over 0·05, S not over 0·06%.

Cold-rolled steel axles.—C not over 0·40, Mn 0·40—0·80, P not over 0·05, and S not over 0·05%. The axles shall conform to the following minimum requirements as to tensile properties:—Tensile strength, 70,000 lb. per sq. in.; elastic limit, 60,000 lb. per sq. in.; elongation in 2 in., 18%; reduction of area, 35%. The test specimen shall bend cold through 180 deg. around a 1 in. pin or mandrel, without cracking on the outside of the bent portion.

Forged and rolled, forged, or rolled solid carbon-steel wheels for engine-truck, tender, and passenger service, or for freight-car service, and wrought solid carbon steel wheels for electric railway service.

Composition.	Acid.	Basic.
C %	0·60—0·80	0·65—0·85
Mn %	0·55—0·80	0·55—0·80
Si %	0·15—0·35	0·10—0·30
P %	not over 0·05	not over 0·05
S %	not over 0·05	not over 0·05

Steel tyres.—Mn not over 0·75, P not over 0·05, S not over 0·05, and Si not over 0·35%.

Tensile properties.	Class A.	Class B.	Class C.
	Tyres for passenger engines.	Tyres for freight engines and for engine truck, tender truck, trailer and car wheels.	Tyres for switching engines.
Tensile strength, lb. per sq. in.	105,000	115,000	125,000
Elongation in 2 in., %	12	10	8
Reduction of area, %	16	14	12

Steel castings.—P and S to be below 0·05%.

Tensile properties.	Hard.	Medium.	Soft.
Tensile strength, lb. per sq. in.	80,000	70,000	60,000
Yield point, lb. per sq. in.	36,000	31,500	27,000
Elongation in 2 in., %	15	18	22
Reduction of area, %	20	25	30

Lap-welded and seamless steel boiler tubes, safe ends, and arch tubes.—C 0·08—0·18, Mn 0·30—0·50, P not over 0·04, and S not over 0·045%.—J. N. P.

Cast iron; Some notes on chilled ——. E. B. Tilt. Proc. Amer. Soc. Testing Materials, 1914. [Advance proof.]

The variations in the properties of cast iron according to its composition and the effect of chilling were examined with a view to determining the most suitable material for car wheels. Wheels were tested by allowing weights to fall repeatedly from definite heights until the flange was broken off, and also by submitting them to a rapid temperature change. The nature of the defects to which the wheels are subject is discussed. Satisfactory metal can be obtained both from charcoal pig iron, and from material prepared from coke pig iron, steel scrap, and ferro-manganese. The carbon content should not exceed 3·5%. The metal was found to be brittle in proportion to the degree of chilling.—J. N. P.

Slag inclusions in open-hearth steel. I. Effects of slag inclusions on the structure of a nickel-steel. F. Giolitti and S. Zublena. Annali Chim. Appl., 1914, **2,** 218—245.

Test-pieces of an acid open-hearth steel containing C 0·38, Mn 0·60, Si 0·22, S 0·008, P 0·02 and Ni 2·02%, and showing slag inclusions, were heated for varying periods (1½ to 15 hours) at various temperatures (1000° to 1190° C.), in some cases under slightly oxidising (decarburising) and in others slightly reducing (carburising) conditions, produced by means of carbon monoxide in contact with soft iron and with carbon respectively (compare Giolitti, this J., 1910, 1456). It is concluded from the results that the direct physical action of slag inclusions is negligible, for by appropriate heat treatment the characteristic injurious effects may be notably diminished and in some cases eliminated. Micrographic examination showed that ferrite which separated during or immediately after a process of carburisation by gases dissolved in the metal was independent of, and separate from, the slag inclusions, whereas that separated during or after decarburising conditions was found, at least in part, around the slag particles and to a greater extent the greater the degree of decarburisation and the less distorted (*e.g.* by mechanical treatment) the crystallisation of the ferrite. In the manufacturing process a condition of equilibrium of oxidation exists between the metal, the slag and the gases, depending upon the temperature. In cooling through the temperature range corresponding to the separation of ferrite, the included slag probably causes decarburisation of the metal immediately in contact therewith and thus induces separation of ferrite, the particles of which act as nuclei for that separating subsequently. Photomicrographs are given in support of the authors' views, which, for the present, are expressly limited to acid open-hearth steel of the kind used in the investigation. Following is an example of the improvement which may be effected by appropriate heat treatment of metal containing slag inclusions:—

	Tempered at 800° and annealed at 500° C.	Subjected to special heat treatment under carburising conditions.
Tensile strength, kilos. per sq. mm.	70·2	71·3
Elongation, %	15	26
Contraction, %	18	47

[*Steel.*] *A failed axle: study of an internal transverse fissure.* R. Job. Proc. Amer. Soc. Testing Materials, 1914. [Advance proof.]

A fault in a steel axle which during working on the lathe led to the development of a transverse crack and longitudinal fissures, was examined microscopically. The fractured section showed evidence of the presence of intense strains produced by unequal cooling of the steel in or after removal from the annealing furnace. Local porosity and slag inclusions pointed in addition to imperfect milling.—J. N. P.

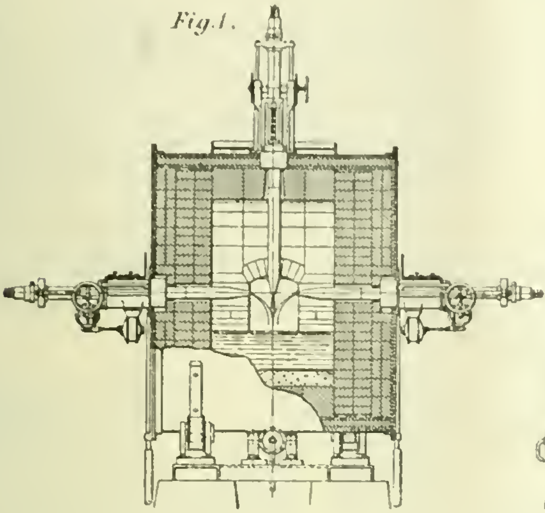
Alloy steels; Magnetic habits of ——. J. A. Mathews. Proc. Amer. Soc. Testing Materials, 1914. [Advance proof.]

The magnetic properties of hardened alloy steels are shown to vary with the physical characteristics of the metal. Alloys hardened by quenching in oil give a lower permeability and residual magnetism but a higher coercive force than those quenched in water. The size of the cross-section of the metal also has an influence, varying according to the hardness of the metal.—J. N. P.

The Rennerfelt electric furnace. Engineering, 1914, **98,** 638—641.

Rennerfelt electric furnaces are now being used on the Continent, and also in England, in the manufacture of steel and iron castings, tool steel, electro-steel from pig iron and ore, etc. The general construction is shown in the accompanying figures. The furnace is usually built with a horizontal, cylindrical steel shell, which can be tilted round a horizontal axis. It is lined first with asbestos, then with silica or "first-quality" bricks, and finally with carbon, silica, or magnesite brick. The charging or casting door may be provided in the side or end of the shell (see Fig. 2). The electric current is brought to the furnace by two horizontal electrodes and one vertical one; the energy is applied in the form of a two-phase current, the vertical electrode being common to the two phases. This arrangement results in the production of an arc which is deflected downwards to the charge in the form of a brush, ensuring uniform heating. The horizontal electrodes may be adjustable vertically as well as horizontally, so that charges of various sizes may be treated in one furnace. The points of the electrodes are usually fixed from 6 to 12 in. from the surface of the bath. The electrodes are composed of Acheson graphite, and are made continuous by means of threaded sockets and dowels; they vary from 1½ in. diameter for the 100 kilo. furnaces to 7 in. for the largest sizes. The 1½ in. electrodes have a capacity of about 70 ampères per sq. cm., whilst the larger sizes can carry 30 to 40 amps. per sq. cm. The voltage at the electrodes should be from 50 to 125 volts, according to the size of the furnace. The electrode consumption in a 600 kilo. furnace, working continuously on charges of cold scrap and pig, has been found to average 2·8 kilos. per ton of steel. A 600 kilo. furnace will melt and refine a full charge of cold scrap with about 700 kw.-hours per ton: the normal rating of such a furnace is 125 kw., but 82 to 90 kw. have been found sufficient to complete a 600 kilo. heat in 5 hours; this indicates a furnace efficiency of about 70%, but the thermal efficiency has been from 85 to 90%. The largest size furnaces of this type, capable of receiving the entire charge of steel from a Bessemer converter or open-hearth furnace up to 75 tons, are subdivided into smaller units by using several sets of electrodes. A 75 ton refining furnace requires about 7500 kw.—T. F. B.

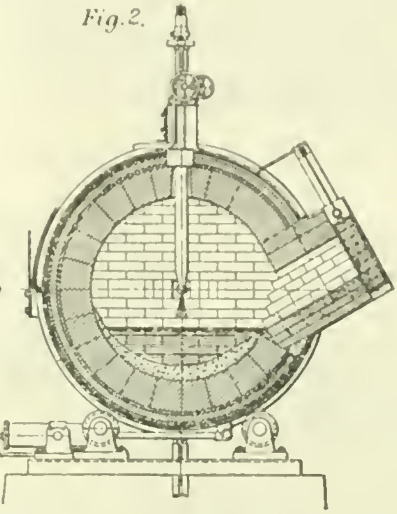
Fig. 1.



Silver ores; Assay of Cobalt ——. A. M. Smoot. Eng. and Min. J., 1914, **98**, 965.

Four portions of the ore, each ¼ or ½ A.T. according as the sample contains more or less than 2000 oz. Ag per ton, are treated separately with strong nitric acid (75 c.c. for ¼ and 100 c.c. for ½ A.T.) and heated until brown fumes cease to be evolved. Each solution is then diluted with 200 c.c. of water, allowed to stand over night, filtered, and the residue washed; any deposit on the beaker is removed with sodium hydroxide, the latter acidified with nitric acid and washed on to the filter paper, which is then dried, treated by "pot assay" or scorified with lead, and the resulting lead button reserved. To the nitric acid solution, sufficient sodium chloride is added to precipitate the silver, the liquid stirred until the precipitate is agglomerated, allowed to stand for 1 hour, and filtered through a double filter; the latter, with the precipitate, is placed upon a disc of assay lead in a glazed scorifier, heated in a closed oven (250°—300° C.) until the paper is completely charred, fine test-lead sprinkled over the residue, the lead button from the treatment of the insoluble residue added, and the whole scorified to produce a lead button (15 grms.) which is then cupelled, both furnace operations being conducted at a low temperature. The method yields higher and more concordant results than are attainable by any all-fire process in which no corrections are made for slag and cupel losses: in 4 assays (¼ A.T. portions) of the same sample the average result was 3293·1 oz. per ton and the maximum difference 8·4 oz. Many brands of test lead contain sufficient bismuth to impair the accuracy of silver assays; the metal employed should be free from this impurity.—W. E. F. P.

Fig. 2.



Alloys of zinc and silver quenched or annealed; Electrical conductivity of ——. G. I. Pétrenko. J. Russ. Phys.-Chem. Soc., 1914, **46**, 175—176. Bull. Soc. Chim., 1914, **16**, 746.

The existence of AgZn (at Zn 36—42%) was indicated on the conductivity and temperature-coefficient curves but not on that of electrical resistance; by prolonged annealing below the transformation temperature (266 C.) AgZn was converted into a phase of variable composition. Ag_2Zn_3 was also indicated on the curve of temperature coefficients; but the phases, Ag_2Zn_5 and $AgZn_6$, appeared to be only solid solutions. $AgZn_1$ was not indicated on the resistance curve.—W. E. F. P.

Hardness of the systems (A) *Ag-Zn and* (B) *Ag-Al.* G. I. Pétrenko. J. Russ. Phys.-Chem. Soc., 1914, **46**, 176. Bull. Soc. Chim., 1914, **16**, 738—739.

(A) The maximum hardness, 220·02 (Brinell), occurred at Ag_2Zn_3, the values for Ag and Zn being 23·2—26 and 30·1, respectively; the phases of variable composition, Ag_2Zn_5 and $AgZn_6$, are indicated as transition points on the hardness curve. (B) The curve consisted of four branches. The maximum hardness (83·6) occurred at $AlAg_2$: at Al 70% the hardness was 49·19, and at Al 14·3%, 75·99. The existence of $AlAg_3$ was not indicated on the diagram.—W. E. F. P.

[*Copper-zinc alloys.*] *Non-ferrous materials; Some considerations affecting specifications for wrought* ——. W. R. Webster. Amer. Soc. Testing Materials, June—July, 1914. [Advance proof.] 14 pages.

The methods employed in producing Cu-Zn alloys in sheets, strips, rods, wire and seamless tubes are briefly described, and the effects of the various operations, and also of certain impurities, upon the properties of the finished materials discussed. The effects of varying proportions of Cu and Zn, of varying amounts of cold rolling, and of varying annealing temperature, are shown by means of curves. Although largely surmountable by the employment of appropriate mill practice and inspection, considerable difficulty is experienced in controlling, within close limits, the large number of variables involved, chiefly because the alloys are produced in comparatively small lots.—W. E. F. P.

Bronze and Monel metal; Effect of acid solutions on ——. S. Croasdale. Eng. and Min. J., 1914, **98**, 873.

THE losses in weight sustained by Krupp bronze and Monel metal, by immersion for 2½ and 3 months in dilute sulphuric acid (H_2SO_4 from 0·12 to 1·50%), varied from 3·22 to 4·55 and from 3·89 to 10·07%, respectively. The corresponding losses, over the same periods, in acidified copper sulphate solutions (Cu from 0·05 to 0·50%) varied from 1·22 to 0·10 and from 14·50 to 2·17%, the copper being completely precipitated by the bronze from all but the two strongest solutions. The losses sustained by Monel metal by immersion for 6 weeks in solutions of sulphuric acid (10%), copper sulphate (10%), and sulphuric acid with copper sulphate (each 10%), were 2·81, 1·99 and 4·88%, respectively.—W. E. F. P.

Non-ferrous castings; Study of the strength of ——; *comparison of different test specimens.* L. P. Webbert. Amer. Soc. Testing Materials, 1914. [Advance proof.] 14 pp.

TENSILE tests of Cu-Sn and Cu-Zn alloys were made on test-pieces respectively cast on the outsides of big castings and cut from different portions of solid castings. With Cu-Sn alloys (typically Cu 88, Sn 10, Zn 2) greater tensile strength and elongation were obtained on metal which had cooled quickly, than on that taken from the inside of a solid casting, the highest results being given by the cast test-pieces. The use of externally cast test-pieces may therefore give misleading (high) results. Similarly, where little machining was required to make the finished test-piece, the thinner specimens gave the higher results, owing to the cross-sectional proportion of quickly-cooled "skin" being greater. With the Cu-Zn alloys the differences observed with test-pieces taken from different positions were much smaller, and an externally cast specimen represented very closely the strength of the casting as a whole.—T. ST.

Zinc; Polymorphism of ——. G. I. Pétrenko. J. Russ. Phys.-Chem. Soc., 1914, **46**, 176—178. Bull. Soc. Chim., 1914, **16**, 740.

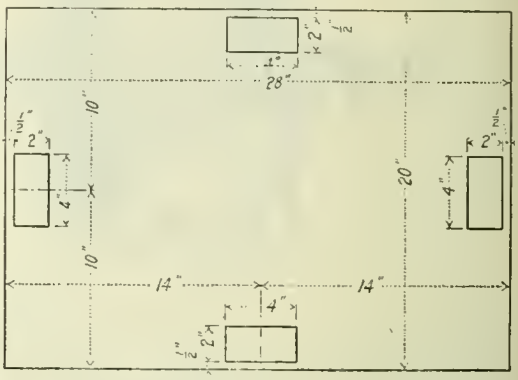
THE polished surface of zinc cooled slowly from above its melting point to 180° C. exhibited large polyhedra (separate or interpenetrating) upon which comparatively few small ones were disposed promiscuously; the small polyhedra were more abundant when the metal was quenched at 360°—330° C., but completely covered the surfaces of the large crystals when the metal was cooled to just below 300° C. The phenomenon was reversible and is regarded as indicating the occurrence of an allotropic transformation between 290° and 300° C.—W. E. F. P.

Nickel-copper-lead alloys; Ternary ——. N. Parravano. Gaz. chim. ital., 1914, **44**, II., 375—384.

WHILST nickel and copper form a continuous series of solid solutions, lead is only partially miscible with nickel and with copper in the molten state, and this condition of partial miscibility is found also in the ternary alloys. Eighty-four alloys were examined, and the isotherms of the beginning of solidification (975°—1390° C.) and of the formation of two liquid strata (970°—1290° C.) are plotted in triangular diagrams. In all cases the temperature of complete solidification was practically identical with the solidifying point of lead. The constituents of the alloys are solid solutions of copper and nickel and nearly pure lead. The results elucidate the method of removing copper and nickel from crude lead by heating it a little above its melting point, when the metals named separate as a crust which can be skimmed off.—A.S.

Tin, terne and lead-coated sheets; Method of sampling and analysis of ——. J. A. Aupperle. Proc. Amer. Soc. Testing Materials, 1914, **14**. [Reprint.] 7 pages.

ONE sheet from each grade or shipment is taken for analysis, and an average sample obtained from it by cutting out four pieces, each 4×2 in., as shown in the figure. After being cleaned with chloroform or other solvent, each piece is cut in halves (2×2 in.), marked A and B respectively, the four "A" halves being weighed together, cut into pieces about ⅛ in. square, mixed and used for the determination of tin and lead, while the four "B" halves are used for determining the weight of coating (as a check) and for the analysis of the base metal. To determine tin, 5 grms. are completely dissolved in 75 c.c. of hydrochloric acid (with the usual precautions against oxidation) and the cold solution titrated with $N/20$ iodine previously standardised against 0·1 grm. of pure tin and 4 grms. of iron filings dissolved together under the same conditions as the assay. For lead, 10 grms. are dissolved in 150 c.c. of nitric acid (1 : 1), brown fumes expelled, and the solution diluted to 1000 c.c.: to 100 c.c. of the solution 10 c.c. of strong nitric acid are added and the liquid electrolysed at 50°—60° C. with a current of 1—2 amp. at 2·3—2·5 volts, the lead being weighed as PbO_2; if manganese be present in the base metal to an appreciable extent, the lead is determined as sulphate. The result for each metal is usually calculated to lb. per case of 112 sheets, 20×28 in. To determine the weight of coating, the four "B" halves, each wrapped with a stiff wire of platinum or nickel, are immersed, horizontally and successively, for exactly 1 min. in 60 c.c. of concentrated sulphuric acid heated to at least 250° C., then momentarily in 50 c.c. of water, and finally rubbed during washing with a further 50 c.c. of the latter. The stripped pieces are dried, re-weighed and used for the analysis of base metal, the loss in weight representing the coating and some iron. The sulphuric acid solution and washings are mixed, 200 c.c. of hydrochloric acid added, the mixture boiled, cooled and diluted to 500 c.c.: of this solution 100 c.c. are used for the determination of iron (being successively oxidised by permanganate, reduced with stannous chloride and titrated with $N/10$ permanganate in the presence of manganese sulphate and phosphoric acid); and 100 c.c. for tin, by reduction with powdered metallic antimony and titration with $N/20$ iodine. The weight of coating as calculated from the data thus obtained should agree very closely with that ascertained in the first determination.—W. E. F. P.



Tin: Artificial twin crystals of ——. P. Gaubert. Comptes rend. 1914, **159**, 680—682.

IF melted tin be allowed to solidify between plane glass surfaces and the polished face be then etched with hydrochloric acid the outlines of the crystals, some rectangular

and others triangular, may be recognised. If solidification has been slow, single crystals may extend over several sq. cm. If the lamina be punctured by a sharp blow with a needlepoint, there is produced :—(1) on the opposite side a cross in relief with branches equal or unequal in length according to the orientation of the crystal surface; (2) two or three series of shining parallel bands, 0·5 mm. in width, extending from the point pressed to the edges of the crystal and making an angle of several degrees with the surface of the lamina. The angle between these bands varies with the crystalline orientation of the surface. Whatever the form of the outline of the crystal (*e.g.* rectangular) as revealed by etching with hydrochloric acid, these bands always bound triangular areas, so that molecules originally arranged in a prismatic face of the crystal undergo re-orientation so as to bound a pyramidal face. The formation of similar bands occurs when a sheet of tin is bent, and is probably the cause of the "cry" of tin. (See also Ewing and Rosenhain, this J., 1900, 1115.)
—J. H. L.

[*Metals.*] *Hardness tests; Relation between Brinell ball-test and scleroscope readings.* J. J. Thomas. Amer. Soc. Testing Materials, 1914. [Advance proof.] 3 pp.

Brinell and scleroscope readings were both taken on each of a large number of metals and alloys, and the results plotted with a view to obtaining a conversion factor. The Brinell tests were made with an "Alpha" machine, having a steel ball 10 mm. in diameter, with a pressure of 3000 kilos. for 30 seconds, and the scleroscope readings were taken with a Shore instrument having a diamond-tipped hammer. The factor for converting the scleroscope reading into the Brinell hardness number is 6·67 for steels, 5·25 for cast-iron and bronzes, about 6 for aluminium, and 7·7 for nickel steels. Metals with a Brinell hardness number above 300, or scleroscope number above 45, were found difficult to machine. Tempered steels gave Brinell numbers from 150 to 300. The scleroscope readings varied more than the ball tests on a given sample, due probably to the very small area actually tested by the scleroscope.—T. St.

Metallic protective coatings; A rational test for ——. J. A. Capp. Amer. Soc. Testing Materials, June—July, 1914. [Advance proof.] 5 pages.

The durability and uniformity of metallic coatings, such as those applied to iron and steel by galvanising, sherardising, etc., are tested by exposure to a "salt fog" produced by projecting into the test chamber an atomised spray of water saturated with sodium chloride. Efficient coatings last for at least a week, while poor ones break down in a few hours (generally less than 24), failure being indicated by the development of spots or patches of rust.
—W. E. F. P.

Metals; The colour of ——. L. V. Martiouchek. J. Russ. Phys.-Chem. Soc., 1914, **46**, 174. Bull. Soc. Chim., 1914, **16**, 751—752.

The following facts are quoted in support of the view that all metals are naturally silver-coloured, the yellow tints of some being due to traces of foreign substances: certain metals (*e.g.* calcium), formerly regarded as yellowish have proved to be white when pure; according to Heine's researches, copper assumes a paler hue (less red) when specially purified, the reddish tint being apparently an oxidation effect due to the presence of lead oxide in the metal: potassium, sodium and rubidium, obtained by reduction of the chlorides with calcium, are coloured yellow when traces of air are present, the colouring effect being due to nitrogen and not to oxygen.—W. E. F. P.

Electrostatic fume precipitation at Anaconda. E. M. Dunn. Eng. and Min. J., 1914, **98**, 873—874. (See also this J., 1914, 1054.)

Experiments were made with a pipe, 20 ft. long and 3 ft. in diameter, containing a central discharge-electrode of nichrome wire (No. 29), the velocity of the gases being 5 cb. ft. per sec. and the e.m.f. 150,000—160,000 volts. The results for blast furnace gases, were not so good as those for mixed roaster and converter gases, but were considered sufficiently promising to justify the erection of an experimental plant in which a pipe 4 ft. in diameter will be employed with an e.m.f. of 220,000 volts. Fractional electrostatic precipitation was effected by passing arsenical gases from a roasting furnace through two treaters in succession; in the first, which the gases entered at about 310° C., practically all the dust was precipitated, while in the second, in which the gases were cooled to 90° C. by admission of air, white arsenic of 99·7% purity was deposited.—W. E. F. P.

Sodium amalgams; specific volumes and electrical conductivities. E. Vanstone. Chem. Soc. Trans., 1914, **105**, 2617—2623.

The volume-concentration diagram of solid sodium amalgams showed discontinuities at 83·0, 73·5, 63·0, 47·5, 32·5 and 20·0 atoms % Na, and confirmed the existence of the inter-metallic compounds shown by the thermal diagram (Vanstone, Trans. Faraday Soc., 1911, **7**, 42). Since the existence of only one compound—$NaHg_2$, at 33·3 atoms % Na (m. pt. 360° C.)—was indicated by measuring the electrical conductivities of the liquid amalgams at high temperatures (Bornemann and Müller, this J., 1910, 884), and no evidence of others could be obtained at temperatures (110° and 135° C.) not far removed from the m. pts. of the alloys, it is concluded that the remaining compounds are completely dissociated in the liquid condition.—W. E. F. P.

Antimony trichloride; Electrolysis of —— in presence of colloids. A. Mazzucchelli. Gaz. chim. ital., 1914, **44**, II, 404—419.

According to Cohen (this J., 1905, 819) the "explosive antimony" obtained by electro-deposition from solutions of antimony chloride consists of a metastable form of antimony in which antimony chloride is present in the form of a solid solution. This metastable form readily changes into the stable form, with evolution of heat, which causes volatilisation of the chloride. The author found that resorcinol, tannin, molybdic acid, starch and gum arabic had no appreciable influence on the nature of antimony deposited electrolytically from chloride solutions. In presence of quinine, casein, peptone, and, especially, of gelatin, brighter and more brittle deposits were obtained, which were nearly incapable of explosion by percussion but exploded on heating; besides the usual content of chloride, they contained a relatively large quantity of organic matter. The results indicate that the antimony chloride in the deposited metal is present as a true solid solution rather than as a colloidal solution.
—A. S.

Zinc concentrates. Chem. Tr. Jnl., Dec. 12, 1914. [T.R.]

At the present moment there are large quantities of zinc concentrates at the Swansea Docks diverted there as prizes of war, but no interest seems to be taken in their utilisation, owing, it is said, to the fact that local spelter makers have no means of treating these concentrates, as they produce their makes from calamine and blende ores only. It should pay our smelters to investigate and adapt their works accordingly.

Copper goods. Board of Trade Bulletin No. 24.

May be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Quick method of precipitating tin electrolytically. Humphreville. *See* XXIII.

Patents.

Iron and alloy product; Metallic —— and process of manufacturing same. C. A. Allison, London. From International Metal Products Co., Newark, N.J., U.S.A. Eng. Pat. 27,966, Dec. 4, 1913.

A modification of Eng. Pat. 27,201 of 1909 (see U.S. Pats. 940,784 and 940,785; this J., 1909, 219, 960) 0·05 to 0·5% P being left in the steel, or added to it, if necessary, as an alloy, which may contain Cu, Ni, Co, V, or Cr in addition.—O. E. M.

Annealing wire coils, iron castings, etc.; Kilns for ——. G. B. A. Gibbons, Lower Gornal, R. Masters, Dudley, and M. van Marle, Lower Gornal. Eng. Pat. 7399, Oct. 28, 1913.

Circular pots containing the objects to be annealed are rolled by gravity through an inclined tunnel heated externally and provided with a water-sealed hood at each end. The pots may have guide flanges to engage rails in the tunnel; a hinged arm lifts the pots up through the inlet hood, and a checking device releases them as required at the outlet end.—O. E. M.

Roasting furnace; Horizontal mechanical ——. P. Sarrasin, Dijon, France. Eng. Pat. 26,915, Nov. 22, 1913.

A horizontal water-cooled shaft with pallets rotates and simultaneously moves from front to back of the furnace, while the ore is fed from back to front. Rotation is stopped, and the pallets clear the ore, on the return stroke. The slots in the furnace sides are closed by an endless belt with an inner asbestos lining sliding in grooves, the lower of which is sealed with refractory sand.—O. E. M.

Copper; Process of extracting —— from carbonate and oxide ores. H. R. Ellis, Salt Lake City, Utah. U.S. Pats. (a) 1,115,521, (b) 1,115,522 and (c) 1,115,523, Nov. 3, 1914; date of appl., June 4, 1914.

The ore is treated with a solution containing an alkaline carbonate or bicarbonate, from which the copper is subsequently recovered (a) by agitation with granulated lead, (b) electrically by the use of a mercury (or amalgamated) cathode and an insoluble anode, (c) by means of a finely divided amalgam of an alkali- or alkaline-earth metal.—W. E. F. P.

Copper; Coating steel or iron with ——. J. E. Sheaffer, Burnham, Pa. U.S. Pat. 1,115,870, Nov. 3, 1914; date of appl., Dec. 3, 1912.

A hollow ingot of copper is made by pouring off the central core while still molten; it is filled up with molten steel or iron, yielding a compound ingot which may be rolled or drawn.—O. E. M.

Tin from waste tinned metal; Process of obtaining the ——. G. von der Linde, Crefeld, Germany. U.S. Pat. 1,116,176, Nov. 3, 1914; date of appl., May 6, 1914.

Air and chlorine are thoroughly mixed before allowing them to act on the scrap.—O. E. M.

Alkali and alkaline-earth metals; Process of producing ——. C. E. Acker, Ossining, Assignor to The Nitrogen Co., New York. U.S. Pat. 1,116,865, Nov. 10, 1914. Date of appl., Aug. 5, 1910.

See Fr. Pat. 420,744 of 1910; this J., 1911, 369.—T. F. B.

Aluminium and the like; Method of insulating wire of ——. E. Presser, Berlin. U.S. Pat. 1,117,240, Nov. 17, 1914. Date of appl., May 31, 1911.

See Fr. Pat. 425,532 of 1911; this J., 1911, 905.—T. F. B.

Alloy of aluminium and process of making. T. A. Bayliss, Warwick, and B. G. Clark, London. U.S. Pat. 1,117,308, Nov. 17, 1914. Date of appl., Aug. 15, 1913.

See Eng. Pat. 19,452 of 1912; this J., 1913, 948.—T. F. B.

Melting-furnace. I. Hall, Birmingham. U.S. Pat. 1,117,666, Nov. 17, 1914. Date of appl., Nov. 13, 1913.

See Eng. Pats. 15,323, 23,493, and 24,081 of 1913; this J., 1914, 835.—T. F. B.

Metal-melting furnace. I. Hall, Birmingham. U.S. Pat. 1,117,667, Nov. 17, 1914. Date of appl., Nov. 13, 1913.

See Eng. Pat. 21,158 of 1913; this J., 1914, 425.—T. F. B.

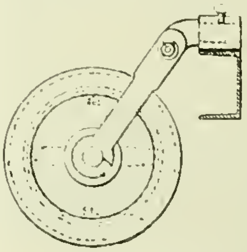
XI.—ELECTRO-CHEMISTRY.

Formation of deposits in oil-cooled transformers. Michie. *See* IIa.

Electrolytic determination of nickel. Marsh. *See* XXIII.

Patent.

Electrolytic apparatus. A. Herrmann, Leipzig-Gohlis, Germany. U.S. Pat. 1,115,671, Nov. 3, 1914; date of appl., Apr. 23, 1914.



"A contact wheel (fig.) having spokes, a narrow, conductive rim, side-discs of non-conductive material, and hook-connections for said discs engaging said spokes."—W. E. F. P.

XII.—FATS; OILS; WAXES.

Halphen's reaction for cottonseed oil; Utz's modification of ——. E. Gastaldi. Annali Chim. Appl., 1914, 2, 203—207.

Utz's modification (Chem. Rev. Fett-Ind., 1913, 291) consists in mixing the oil with an equal volume of a 1% solution of sulphur in pentachloroethane, with or without addition of amyl alcohol, and heating the mixture to boiling. It is shown that the coloration produced (yellow to orange or brown or almost black) varies according to the temperature or time of heating, and that the reaction is not characteristic of cottonseed oil but is given also by other oils and by palmitic, stearic and oleic acids. The rapidity of the author's modification of Halphen's reaction (see this J., 1912, 934) may be increased and the quantity of carbon bisulphide necessary diminished by using a higher temperature. Five c.c. of the oil are treated with 5—6 drops of a solution of sulphur in carbon bisulphide and 3—4 drops of pyridine and heated for 4—5 minutes over a direct flame to not above 140° C.: the characteristic wine-red coloration is obtained if cottonseed oil be present.—A. S.

Hydrocarbons; Rapid method for the detection and determination of solid —— in admixture with fatty acids. G. Verona-Rinati. Annali Chim. Appl., 1914, 2, 201—202.

Solid fats and fatty acids are readily soluble in α-dichlorhydrin whether this be anhydrous or saturated with water, whereas solid hydrocarbons (paraffin wax, ceresin, ozokerite, etc.) whilst appreciably soluble in the anhydrous solvent on heating above their melting point, are practically insoluble in α-dichlorhydrin saturated with water. To detect solid hydrocarbons in solid fats or fatty acids, 7 c.c. of α-dichlorhydrin are mixed in a graduated test-tube with 1·2 c.c. of water and 1·43 grm.

of the substance under examination, and the tube is corked and heated in a water-bath at 65° C., with occasional agitation: each 0·1 c.c. of insoluble matter corresponds to 5% of mineral hydrocarbons in the original substance. To distinguish between paraffin and ceresin, 0·2 grm. of the dried insoluble matter is dissolved by heating with 10 c.c. of anhydrous α-dichlorhydrin, the solution allowed to cool and the temperature at which a turbidity appears noted: this is 80°—92° C. for paraffin and 112°—115° C. for ceresin.—A. S.

Kapok and akon and the bitter principles, wax and resin contained therein. H. Matthes and L. Streicher. Arch. Pharm., 1913, **251**, 438—452. Bull. Soc. Chim., 1914, **16**, 115—116.

Kapok and akon fibres contain respectively 8·6 and 7·2% H_2O. Crude kapok yields 3·58% and purified kapok 0·93—2·62% of ash: purified akon yields 3·61%. A mixture of equal parts of alcohol and benzene extracts 4·97% of wax from kapok and 4·63% from akon. The characters of the waxes from kapok and akon respectively are: m. pt. 24° C., 30·5° C.; n_D^{33} = 1·4618, 1·4682; a_D = 0, acid value, 59·85, 65·09; saponif. value, 170·14, 171·52; iodine value, 69·41, 70·52; Reichert-Meissl value, 2·02, 1·76; Polenske value, 0·97, 1·05. The waxes contain respectively 28% (kapok) and 31% (akon) of unsaponifiable matter, composed chiefly of phytosterols and melissyl alcohol, together with 0·6% of a hydrocarbon, $C_{21}H_{42}$, m. pt. 69° C., identical with laurane: the crude phytosterol from akon wax contains stigmasterol, m. pt. 170° C., and a phytosterol of m. pt. 136° C. The fatty acids of kapok wax consist of 15% of solid and 85% of liquid acids: those of akon wax contain 20% of solid and 80% of liquid acids. The solid acids appear to consist entirely of palmitic acid: the liquid acids contain oleic acid 61, linolic acid 38, and linolenic acid 1%. (See also this J., 1913, 917.)

Kapok and akon contain from 4·74—9·74% of substances soluble in water, among which is a very poisonous, non-nitrogenous, bitter substance, which gives a blue coloration with sulphuric acid and potassium bichromate: the bitter principle of akon resembles picrotoxin in some respects. —A. S.

Palmnut kernel cake. Murray. *See* XIXa.

Viscosity measurements and a new viscosimeter. Flowers. *See* XXIII.

Patents.

Grease and other substances; Presses for extracting ——. T. W. and G. H. Mays, Bourne, Lincolnshire. G. Fortescue, and E. S. and G. Cowen, Nottingham. Eng. Pat. 24,622, Oct. 30, 1913.

The casing comprising the body of the press is provided with a hinged door, a rib passing round the door fitting into a recess filled with packing material on the casing so as to form a tight joint when the door is closed. The piston is fitted on to a screw shaft passing through the top of the casing and operated by a rotating nut. A grid plate for supporting the material rests on ridges at the bottom of the casing, which form channels for the expressed grease. Steam under pressure is admitted into the upper part of the casing and, after passing through the material being pressed, escapes with the grease, etc., through an outlet at the lower part.—W. P. S.

Soap; Manufacture of ——. C. Pleines, Utrecht, Holland. Eng. Pat. 24,795, Oct. 31, 1913. Under Int. Conv., Nov. 6, 1912.

See Fr. Pat. 464,335 of 1913; this J., 1914, 557.—T. F. B.

Glycerine containing salt; Means for distilling ——. F. J. Wood, Brooklyn, U.S.A. Eng. Pat. 24,920, Nov. 1, 1913.

See U.S. Pat. 1,089,383 of 1914; this J., 1914, 363.—T.F.B.

System for cleaning and purifying oils and other liquids. U.S. Pat. 1,115,827. *See* I.

Catalytic hydrogenation. Eng. Pat. 21,815. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Lacquer; A chemically resistant glass ——. P. J. Fox. J. Phys. Chem., 1914, **18**, 759—761.

Fifteen grms. of pure, firm unvulcanised rubber are treated with 100 c.c. of carbon bisulphide, and after a few hours 30 grms. of white ceresin, cut into small pieces, and 100 c.c. of carbon bisulphide, are added to the homogeneous mixture. The resulting lacquer should be less viscid than glycerin. The cleaned glass vessel is rinsed with absolute alcohol, drained, one-third filled with lacquer, shaken gently round, and immediately drained. A smooth, translucent coat is thus obtained, especially if the process is modified by applying two layers of a somewhat thinner lacquer with an intermediate interval of 1 to 5 hours. Carbon tetrachloride may be substituted for carbon bisulphide if the lacquer is made thicker and applied hot. The protective coating is very effective with careful usage: a bottle so treated was filled with distilled water of conductivity 2·45 reciprocal megohms and rotated for 70 hours in a thermostat at 20° C. whereby the value rose only to 2·98, whilst a similar unlacquered bottle gave the value 58·0 under identical conditions.—J.R.

Use of poisons for plants in agriculture and industry. Crivelli. *See* XVI.

Oxidation of the nopinene (β-pinene) in Spanish oil of turpentine. Madinaveitia. *See* XX.

Patents.

Metallic paint; Process for the manufacture of a [quick-drying] ——. A. Finkler, Moscow. Eng. Pat. 8126, March 31, 1914.

A dry mixture of powdered zinc-white, white lead, and aluminium is added to a solution of shellac so as to form a thin paste, which is made up to the proper consistency by adding a solution of celluloid in acetone. For example, 1 kilo. may contain 700 grms. of celluloid solution, 30 of aluminium, 100 of shellac solution (in spirit), 130 of white lead, and 40 of zinc-white. The paint is not affected by humidity or high temperatures. Colouring matters may be added to the shellac solution.—F. Sodn.

Coating compositions; Manufacture of ——. G. Cuneo, Genoa, Italy. Eng. Pat. 5432, March 3, 1914. Under Int. Conv., March 3, 1913.

See Fr. Pat. 469,144 of 1914; this J., 1914, 973.—T. F. B.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber and the war. J. McEwan. India Rubber J., 1914, **48**, 941.

The existing serious shortage of raw rubber in Germany is referred to, and also the steps taken by the British Government, upon representations from the trade in this country, to prevent supplies entering Germany. The importance of rubber in the conduct of modern warfare is emphasised. Tyres: aeroplane and airship fabrics: ground-sheets, waterproof capes, cloaks, saddle-covers; "Wellingtons"; rubber swimming collars; hot-water bottles and other surgical goods are among the more obvious articles involving the use of rubber. But large quantities are employed for more obscure purposes, such as rubber packings, washers, linings, etc., in warship construction, particularly in submarines, to ensure perfect watertightness. The possibility of making up the deficiency of natural rubber by means of a synthetic product is a somewhat remote one.—E. W. L.

Rubber ; Methods for the preparation of artificial —— from different raw materials, including petroleum. E. Pyhäla. Neftjanoje Djelo, 1913, No. 17. Petroleum, 1914, **9**, 1376.

The fraction of Baku petroleum boiling between 98° and 106° C. yields up to about 20% of its weight of adipic acid, which, by way of the amide, can be converted into butadieen and synthetic butadiene-rubber. This method of preparation is however hardly possible from a commercial standpoint. If, however, the butadiene hydrocarbons could be obtained from the petroleum hydrocarbons by a simple, direct process this route to synthetic rubber would be a a good one.

The author is of opinion that use might be made of the emulsions obtained with the turpentine-like and other hydrocarbons of petroleum by the aid of certain emulsifying agents, which emulsions are very similar to rubber latex, and, like the latter, can be worked up into rubber-like products.—E. W. L.

XV.—LEATHER ; BONE ; HORN ; GLUE.

Precipitated bone. Jenkins and Street. *See* XVI.

Patents.

Leather ; Manufacture of ——. O. Röhm, Darmstadt, Germany. U.S. Pat. 1,117,912, Nov. 17, 1914 ; date of appl., May 7, 1914.

Leather is softened by impregnating it with a mixture of sulphonated oil or fat (free from soap) and unaltered oil or fat.—G. W. McD.

Keratin compound; Indurated ——. B. B. Goldsmith, New York. U.S. Pat. 1,114,981, Oct. 27, 1914 ; date of appl., Jan. 4, 1912.

Keratin is subjected to the combined action of a converting and an indurating agent, *e.g.*, β-naphthol and formaldehyde, and the mass is mixed whilst heating, preferably under pressure.—F. Sodn.

XVI.—SOILS ; FERTILISERS.

Potash ; Ashes of hedge-clippings and trimmings as a source of ——. E. J. Russell. J. Board Agric., 1914, 21, 694—697.

Ashes obtained from the green and dead woods, the grass and weeds from hedging and ditching, burned in the open in the customary manner, contained on an average 10·9% K_2O. The waste material from threshing floors yielded an ash containing 11% K_2O. The potash is present as carbonate which is very readily dissolved by rain ; a heap of ash, after a wet night, had lost half its potash. The amount of ash obtained from the trimmings of 100 yds. of hedge is about 15 lb. The cost of obtaining this is about 8d. per lb., charging the whole cost to the ash. The ash after sifting is a very light powder which mixes well with superphosphate, but has not the keeping qualities of kainite.—J. H. J.

Calcium cyanamide and Chili saltpetre ; The fertilising effect of a mixture of ——. P. Bolin. Meddelande No. 79 från centralanstalten f. jordbruksförsök, 1913, 1—18. Biedermann's Zentr., 1914, **43**, 160—162.

No generalisation with regard to the comparative manurial actions of the two fertilisers is possible, but in the numerous cases in which the two are approximately of equal value, a mixture of the two gives higher yields both of grain and straw than either constituent alone. The addition of Chili saltpetre does not increase the manurial power of calcium cyanamide, where the latter by itself has little fertilising action.—O. R.

Nitrogenous fertilisers. P. Wagner. Hess. landw. Zeits., 1913, No. 14. Biedermann's Zentr., 1914, **43**, 162—166.

Comparisons were made during three successive years on crops of winter rye, sugar beet, and barley, in rotation. Of the fertilisers used, Chili saltpetre and calcium nitrate gave the best results, crude calcium cyanamide (nitrolim) had only from one-third to one-quarter of the manurial value of the nitrates, and calcium nitrite proved irregular and unsatisfactory. Ammoniacal superphosphate was about equal to the nitrates in the case of beet, but had only about 65% of their efficiency in the case of barley. —O. R.

Magnesia ; Fertilisation of sugar beet with ——. F. Strohmer and O. Fallada. Oesterr.-ungar. Z. Zuckerind. und Landwirtschaft, **42**, No. 2, 221. Biedermann's Zentr., 1914, **43**, 170—174.

The formation of sugar in the sugar beet depends on the quantity of chlorophyll present, and chlorophyll, according to Willstätter and Hug, contains about 3% Mg. A dressing of 150 kilos. of magnesium sulphate per hektare (about 134 lb. per acre) produced no increase in the root or leaf growth of the beet nor in the content of chlorophyll and sugar.—O. R.

Bone ; Precipitated ——. E. H. Jenkins and J. P. Street. Thirty-seventh Report of The Connecticut Agric. Exper. Stat., 1913, 117.

"Precipitated bone," a by-product of glue manufacture, is a white neutral powder, which is chiefly used as a tobacco fertiliser. Analyses of seven varieties on sale showed that it contains : water-soluble P_2O_5, 0·94 to 1·31 ; citrate-soluble P_2O_5, 33·16 to 38·08 ; total P_2O_5, 34·38 to 39·40%.—W. P. S.

Poisons for plants ; Use of —— in agriculture and industry. E. Crivelli. L'Ind. Chim. Min. e Met., 1914, **1**, 409—413.

Bertrand does not admit that the use of colloidal silver or copper claimed by Lumière (this J., 1911, 1463) has any stimulative action upon the growth of plants. On the other hand, Javillier (see this J., 1914, 563) has found that metallic zinc promotes the growth of *Aspergillus niger.* Fungicides in the form of precipitates sparingly soluble in water are more effective for plants than solutions, since they are only slowly removed from the leaves. *Destruction of weeds :*—In America a solution of copper sulphate containing 5 to 15% iron sulphate is used to kill the weeds in cereal crops, whilst in tropical countries arsenical weed-killers are used on the railway tracks. A typical preparation used by a South American railway company consists of 72 grms. of arsenious anhydride and 15·5 grms. of caustic soda per 100 c.c., coloured with phenolphthalein. This has a sp. gr. of 1·746 and is used at a 10% dilution (1 litre per sq. m.), every 3 months for the first year, and subsequently every 6 months. The railway companies of Columbia and Ecuador employ a mixture in equal parts of 17% sodium nitrate and 20% arsenious acid solutions. Sodium sulphide being too dear the use of barium or calcium sulphide is suggested for this purpose (compare also U.S. Pat. 1,076,818 ; this J., 1913, 1165).

Submarine paints: According to Carbonelli (*Indust. Chim.*, VIII. [23 and 24]); paints for ships' bottoms, etc., usually contain one or more of the following toxic agents :—Nicotine, strychnine, thiocyanic acid, mercury, copper, lead, arsenic, antimony, etc.: whilst the most common substance is mercury arsenite. Collignier gives the following analysis of a submarine paint in great demand: Crystallised copper sulphate, 40·0; iron oxide, 13·78; lead oxide, 1·51; and mercuric chloride, 8·97%.—C. A. M.

Potash salts. Summary for 1913. Phalen. *See* VII.

Fish meal and fish manure. See XIXa.

Patents.

Seed grain; Treatment of ——. C. E. De Wolf, London, and H. E. Fry, Dorchester. Eng. Pat. 10,202, April 24, 1914. Addition to Eng. Pat. 22,151, Oct. 1, 1913 (this J., 1914, 1067).

Grain (one bushel) is steeped in a solution of manure or nitric acid (6 galls.), and placed in a wooden box fitted with iron electrodes in the form of sheets covering the ends of the box. A current of 200 volts and 1¼ ampères is used at not above 27° C. The solution is then drained off, and the grain is sprayed with one quart of petroleum or benzoline.—G. W. McD.

Superphosphates; Method of manufacturing double ——. T. L. Willson; Ottawa, Canada. Eng. Pat. 25,856, Nov. 11, 1913.

See U.S. Pat. 1,078,887 of 1913; this J., 1914, 35. Ammonia, or a compound of ammonium or potassium, may be added to the product.—T. F. B.

Ammonium phosphate [for fertilising purposes, from gas liquor]; Process of making ——. F. S. Washburn, Nashville, Tenn. U.S. Pat. 1,115,044, Oct. 27, 1914; date of appl., June 9, 1914.

Gas liquor (preferably concentrated) is added to boiling crude phosphoric acid, whilst steam is passed through the mixture to remove volatile impurities.—F. Sodn.

XVII.—SUGARS; STARCHES; GUMS.

Beet; Formation of sugar in the ——. H. Colin. Comptes rend., 1914, **159**, 687—689.

The sugar transferred from the leaves to the root consists not only of ready-formed sucrose but also of reducing sugar which is converted into sucrose in the root. The root is never free from reducing sugar, but the ratio of the latter to the sucrose present diminishes (*e.g.*, from 0·178 : 1 to 0·011 : 1) as the plant develops. This ratio sometimes attains 0·2 : 1 in the upper extremity of the root, and usually exceeds 1 : 1 in the base of the leaf-stalks. The disappearance of sucrose from the leaves at night (*i.e.*, in absence of light) is not simply due to its transference to the root, for it undergoes decomposition in the leaves themselves which contain inverting agents. The double function of the root, *viz.*, to store sucrose and to produce it from reducing sugar, renders it possible for different varieties of beets having leaves which elaborate different quantities of sucrose, to have roots equally rich in this sugar.—J. H. L.

Sugar beet; Relation between the weight and sucrose content of the —— *and the surface of the soil.* H. Pellet. Sucr. Indig., 1914, **84**, 59—61, 84—88, and 104—108.

Experiments made by Munerati, Mezzadroli, and Zapparoli of the Beet Cultivation Station, Rovigo (Italy), have shown that there exists no relationship between the surface of soil at the disposal of a sugar beet and its weight. At times so-called "giant" roots weighing 10 to 15 and even 20 kilos. are found, but these are produced more frequently in very fertile than in moderately fertile or poor soils and during seasons of considerable rain (as, *e.g.*, 1913). It has moreover been noticed that the presence in the field of fodder beets amongst sugar beets in no way hinders the growth of the latter.—J. P. O.

Enzymes of honey. F. Gothe. Z. Unters. Nahr. u. Genussm., 1914, **28**, 273. Pharm. J., 1914, **93**, 809.

Lactase, proteases (peptic and tryptic enzymes), and lipases cannot be found in honey, but probably there is an inulase. The invertase of honey is of vegetable as well as of animal origin. The quantities of catalase and diastase are not proportional; often a high diastase corresponds with a low catalase figure. The diastase figure is very important for the valuation of honey because it is not dependent on the food, the diastase being a secretion of the body of the bee. A high diastase figure excludes suspicion of adulteration. A medium diastase figure, in combination with the reaction of Fiehe and other chemical reactions, confirms suspicion of adulteration; and a sample with a low diastase number is either adulterated or overheated.

Sugar beet culture. Times, Dec. 23, 1914.

An attempt is being made by the London and South Western Railway Company to encourage sugar-beet culture in the south-western counties, where it is declared that large areas are thoroughly suitable for the cultivation of beet. It has been announced that, given the requisite production of beet, the capital for the foundation of a factory (some £130,000) would be forthcoming, and every accommodation in the way of sidings and carriage facilities would be provided.

Fertilisation of sugar beet with magnesia. Strohmer and Fallada. *See* XVI.

Patents.

Starch; Manufacture of —— *[and a foodstuff].* C. C. Moore, Washington, D.C. Eng. Pat. 530, Jan. 8, 1914.

Succulent materials such as potatoes, cassava, etc., are reduced to fragments, dried rapidly at a temperature below the gelatinising point until they become brittle, ground dry to a powder which will pass through a 80- or 100-mesh sieve and then ground with water and the starch separated in the usual manner. The effluent may be evaporated to produce a foodstuff.—J. F. B.

Sugar; Process of bleaching ——. M. Barrios, Habana, Cuba. U.S. Pat. 1,117,154, Nov. 17, 1914. Date of appl., May 2, 1912.

See Fr. Pat. 447,206 of 1912; this J., 1913, 248.—T. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Patents.

Malt; Apparatus for producing ——. R. E. Chichester, Norwich. U.S. Pat. 1,117,323, Nov. 17, 1914. Date of appl., July 28, 1913.

See Eng. Pat. 17,904 of 1912; this J., 1913, 804.—T. F. B.

Alcohol; Apparatus for continuously distilling ——. A. L. Obrador, Hagonay, Philippine Islands. Eng. Pat. 12,142, May 16, 1914.

See U.S. Pat. 1,106,832 of 1914; this J., 1914, 978.—T.F.B.

Pressure filters [for beer and the like]. Eng. Pat. 24,768. *See* I.

XIXa.—FOODS.

Cheese; The lactose content of ——. J. P. Street and L. B. Mendel. Thirty-seventh Report of The Connecticut Agric. Exper. Stat., 1913. 95.

Cheeses which have not been ripened, such as cottage, cream, and Neufchatel, contain from 0·8 to about 2·5% of lactose, whilst those which have been subjected to a long ripening process, such as Roquefort, Camembert, Edam and cheddar, are free from lactose.—W. P. S.

Chocolate and cocoa preparations [for diabetics]. J. P. Street and L. B. Mendel. Thirty-seventh Report of The Connecticut Agric. Exper. Stat., 1913. 64—66.

Seven brands of chocolate, four of cocoa and one of chocolate-coated almonds, all recommended for consumption by persons suffering from diabetes, were examined. The chocolates contained from 10 to 50% of carbohydrates, 11 to 25% of protein, and 25 to 61% of fat; added protein appeared to be present in all the samples, but in only three cases did the percentage of carbohydrates fall much below that found in ordinary plain chocolate, namely, about 25%. The cocoas contained from 21 to 51% of carbohydrates, 18 to 53% of protein, and 11 to 24% of fat. The chocolate almonds contained only about 16% of carbohydrates.—W. P. S.

Palmnut kernel cake. J. A. Murray. J. Board Agric., 1914. **21**, 697—701.

The modern method of making the cake is to separate the kernels from the pericarp of the fresh fruits, to partially cook the kernels in order to destroy the enzyme that causes the oil to go rancid, and then to crush the kernels heavily to express the oil. As a result the cake contains much less woody fibre and oil than formerly, the other constituents being increased correspondingly. A recent sample contained: proteins 18·5, oil 5·5, carbohydrates 50·0, crude fibre 10·0, moisture 12·2, and ash 4·0%.—J. H. J.

Fish meal and fish manure. J. Board Agric., 1914. **21**, 688—694.

English fish meal in general has a content of 55—65% of protein, 3—6% of fat and 14—18% of calcium phosphate. The feeding value of the meal depends upon its high content of proteins, of which 90% are digestible. The calcium phosphate and also the salt (0·7% and upwards) are indispensable in the feeding of animals, but the proportion of salt should not exceed 5%. Recent English experiments seem to show that the addition of fish meal to other foods will lead to a marked increase in weight in the animals fed.

Fish manures depend for their manurial value upon their content of nitrogen and phosphate, and in lesser degree upon potash and lime. The variations in these contents are great, depending upon the class of material from which the manure is made. In 19 samples the amounts of nitrogen varied from less than 1 per cent. to over 11 per cent., the phosphates varied from about 8—34%, and the potash from 2—4%. Correspondingly the money values of the samples varied from £2—£10 per ton. Most of the nitrogenous constituents of fish manure resist attack to a greater or less degree, so that the manurial action is gradual throughout the season. The manure is injurious to germinating seeds and plant rootlets until the first active fermentation is over. It does not keep well in storage. (See also this J., 1914, 1066.)—J. H. J.

Manganese in mineral springs of the Central Plateau. F. Jadin and A. Astruc. J. Pharm. Chim., 1914, **10**, 412—416.

A litre of the mineral water was evaporated to dryness and the manganese in the residue estimated colorimetrically after conversion into permanganate by Marshall's method (see this J., 1911, 650). The amounts found in a litre of the water from 72 different springs varied between 1·200 mgrms. (Saint-Galmier, Source Badoit) and 0·020 mgrm. (Royat, Source Velleda). The manganese content can be used to identify rapidly the source of a mineral water or to judge of the genuineness of a sample.—F. Shdn.

Enzymes of honey. See Gothe. XVIII.

Ozonisation of air. Franklin. *See* XIXb.

Patents.

Emulsions [for margarine, etc.]; Production of ——. S. H. Blichfeldt, Southall. Eng. Pat. 25,265, Nov. 5, 1913.

A horizontal cylindrical casing, mounted on a hollow central shaft fitted with agitators, is divided into compartments by perforated partitions. One ingredient of the emulsion is introduced through an opening at the end of the cylinder, and the emulsion is discharged at the other end. The second ingredient (usually the fatty one) is admitted through a pipe passing down the central shaft. This pipe is perforated and, when the perforations come opposite similar ones in the rotating shaft, the ingredient mixes intermittently with the contents of the cylinder. A valve device, such as that described in Eng. Pat. 7499 of 1912 (this J., 1913, 763) or 23,653 of 1913, may be used for the intermittent supply of the second ingredient. —W. P. S.

Emulsions [for margarine, etc.]; Production of ——. S. H. Blichfeldt, Southall. Eng. Pat. 18,048 of 1914; date of appl., Oct. 18, 1913.

A rotating disc provided with slots is mounted on a hollow shaft in a casing the walls of which closely approach the sides of the disc. One of the ingredients of the emulsion is admitted through the hollow shaft whilst the other (usually the fatty ingredient) may enter through a tube extending transversely across the casing and communicating with the interior through small openings at different distances from the axis. The emulsion leaves the apparatus through an outlet near the periphery of the casing. A similar apparatus is described for rendering a partially formed emulsion homogeneous.—W. P. S.

Baking preparations. E. C. R. Marks, London. From Victor Chemical Works, Chicago, U.S.A. Eng. Pat. 5111, Feb. 27, 1914.

See U.S. Pat. 1,113,632 of 1914; this J., 1914, 1109. A tartrate, metaphosphate, or pyrophosphate may be used in place of the disodium phosphate.—T. F. B.

Flour; Process of making dry-shortening ——. A. W. Estabrook and H. E. Weaver, Kansas City, Kans., Assignors to The Larabee Flour Mills Co., Hutchinson, Kans. U.S. Pat. 1,117,011, Nov. 10, 1914; date of appl., June 16, 1913.

Flour is mixed with powdered sodium stearate and an equivalent amount of calcium acid phosphate (see also this J., 1914, 938).—W. P. S.

Flour; Dry-shortening ——. A. W. Estabrook, Kansas City, Mo., Assignor to The Larabee Flour Mills Co., Hutchinson, Kans. U.S. Pat. 1,117,012, Nov. 10, 1914; date of appl., Nov. 24, 1913.

Wheat flour is mixed with finely-divided hydrogenised cottonseed oil, and leavening and seasoning substances. —W. P. S.

Separators for liquids [milk]; Centrifugal drum ——. J. Melotte, Remicourt, Belgium. Eng. Pat. 7839, March 28, 1914.

The bowl of the separator is provided with a false bottom having a peripheral, vertical rim perforated with small holes, through which the denser portion of the liquid (milk) is discharged along with only a minimum quantity of the lighter liquid (cream).—W. H. C.

Fish and other food substances; Method of and apparatus for cooling and freezing ——. N. Dahl, Trondhjem, Norway. Eng. Pat. 6711, March 17, 1914. Under Int. Conv., March 19, 1913.

A liquid is cooled below 0° C. by circulating it through a chamber divided into a number of compartments each containing a mixture of ice and salt or provided with refrigerating pipes. The partitions forming the compartments in this chamber have openings so arranged that the liquid takes a zig-zag course through the chamber and has its level lowered in each successive compartment. Siphon-like pipes distribute the cooled liquid from the delivery pipe on to the fish, etc., and a collecting channel provided with a screen returns the liquid to the cooling chamber.—W. P. S.

Cocoa and chocolate substances; Method for roasting ——. F. E. F. Neumann, Wandsbek, Germany. U.S. Pat. 1,117,594, Nov. 17, 1914. Date of appl., March 28, 1913.

See Fr. Pat. 463,325 of 1913: this J., 1914, 371.—T. F. B.

Manufacture of starch [and a foodstuff]. Eng. Pat 530. *See* XVII.

XIXb.—WATER PURIFICATION; SANITATION.

Air of railway tunnels; Gaseous impurities in the ——. A. Seidell and P. W. Meserve. U.S. Public Health Service, Hygienic Lab., Bull. No. 92, June 1914, 1—47.

Methods for the determination of sulphur dioxide based on the aspiration of the sample of air through a small volume of liquid followed by a gravimetric or volumetric determination of the retained sulphur dioxide could not be used, but satisfactory results were obtained by direct titration with $N/1000$ iodine solution, after applying a correction (see this J., 1914, 499). When samples of air were kept in moist bottles, practically the whole of the sulphur dioxide disappeared within 1 hour; in dry bottles the loss during the first 2 hours was usually inconsiderable, although with very small quantities an appreciable loss may take place within 30 minutes. Of quite small amounts of sulphur dioxide liberated in a closed room only about 30 to 60% could be recovered. The iodine pentoxide method (see this J., 1907, 1251; 1908, 595; 1909, 1170; 1914, 499) was used for the determination of the carbon monoxide, special bulbs, having narrow connecting tubes, being employed for the absorption of the resulting carbon dioxide and liberated iodine, and the closed aspiration system was adopted in passing the sample of air through the apparatus. Analyses of test mixtures of very small amounts of carbon monoxide with air showed that from 88 to 98% of the former could be recovered. Eighty-eight samples of air from tunnels were examined; those from tunnels through which steam locomotives passed contained on an average 15·1 parts SO_2 and 267 parts CO per million, whilst the corresponding figures for the tunnel on the electric railway were 2·9 and 25 parts, respectively. A review of the available literature on the physiological effects of small amounts of these two gases showed that the concentrations of the gases which produce an unmistakable harmful effect upon man are somewhat greater than the maximum amounts which were found in any of the tunnel-air samples examined.—W. P. S.

Air; Ozonisation of ——. M. W. Franklin. J. Ind. Eng. Chem., 1914, **6**, 850—855.

Ventilation.—The modern practice of ventilation is concerned only with the absorption of the heat produced by the inmates of a room, with removal of the expired moisture, and destruction of the odours of men, animals and organic substances. Ozone is most useful in those places where perfect ventilation is impossible. It does not simply mask the organic odours, but destroys them. Onions, decayed fish, decomposed meat, etc., treated with ozonised air had a strong smell of ozone, and after treatment with ferrous sulphate solution to remove the ozone, the substances were free from their natural odour. Chemical compounds produced in the decomposition of organic matter, as skatole, and valeric and butyric acids, are destroyed also. No instance of harm to individuals from the use of ozone in proper concentration in air has been recorded; the workers in the London tube railways and those on water-sterilisation plant have shown no ill effects. The use of ozone in quantity to sterilise the air of rooms involves irritation to the respiratory tract. Experiments to determine its germicidal action have given inconclusive results. Its usefulness is not due to any beneficial effect on the human economy but to the fact that it destroys harmful organic emanations in the air. *Odour destruction.*—Disagreeable odours are given off in the manufacture of casein. Experiments with undried commercial casein showed that the odour was destroyed in the presence of ozonised air and that the least quantity of ozone required was 1·84 mgrms. per litre of air contaminated with the odour from 15 grms. of casein. In experiments with tobacco smoke, it was found that ozone combined only with the volatile components of the smoke, rendering the smoke odourless, tasteless and non-irritative, but that it did not oxidise the carbon particles. There was however a slight diminution in the smoke density when the air was ozonised: equal weights of tobacco were burned and the smoke collected with equal volumes of air and ozonised air, and in the bottle containing the latter mixture a marked clearing was effected in 4 hrs. as compared with the other bottle. Pieces of different kinds of cloth were exposed to tobacco smoke until they had a strong odour; they were then treated with ozonised air and were thoroughly deodorised within half an hour. *Food preservation.*—The effect of ozone on egg-albumin was examined and it was found that considerable coagulation took place and the albumin turned a yellowish-grey colour. Eggs were placed in bottles which were exhausted and then filled with ozonised air. After 10 days, all the ozone had disappeared and the bottles were recharged and examined every ten days. After 60 days the eggs ceased to taste fresh; the loss in weight was about 1·5%. In a control series in the absence of ozone, the eggs began to turn stale after 20 days when the loss in weight was 0·5%. The action of the ozone is to lessen the number and activity of the bacteria which penetrate the shell during evaporation under ordinary conditions.—J. H. J.

The campaign against smoke. English and American results. Times Eng. Suppl., Nov. 27, 1914, 146.

One of the chief obstacles in the past to the progress of the smoke-abatement movement has been the lack of accurate scientific data relating to the character and amount of the pollution of the atmosphere from smoke, and to the extent of the damage and losses arising from this cause in the more important cities and industrial centres.

A central body or committee was required which should formulate and carry out a scheme of co-operative work and investigation, based on the use of scientific and uniform methods and apparatus. This need has now been met by the work of the Committee for the Investigation of Atmospheric Pollution, appointed by the London Smoke Abatement Conference of 1912, and in America by the Commission of Experts, appointed by the Mellon Institute of Industrial Research attached to the University of Pittsburgh.

Work of the London Committee.—During the past two years the London Committee has carried out useful preliminary work:—(1) By selecting and drawing up the specification for a standard method and form of apparatus for the collection of the soot and other impurities of the atmosphere; (2) by formulating the conditions under which this apparatus should be used, and the collected soluble and insoluble impurity examined; and (3) by obtaining the co-operation of the health authorities of many of the larger towns and cities of the country for the investigation. The method selected for the observations is based on the collection of the whole of the rainfall for one month in one or more large bottles, and the determination of the weight and character of the suspended and dissolved impurities, by subsequent filtration and evaporation of the collected water. This method was employed for the observations upon the sootfall of London, carried out by the Coal Smoke Abatement Society and the "Lancet" in 1910, and also for the observations by Prof. J. B. Cohen, in Leeds. It does not give the amount of suspended air pollution in the strictest meaning of the term, but only the proportion of it which falls, or is carried down by the rain and snow in a given time; but the latter is the weight which is most important from a practical point of view, in respect of air pollution.

Apparatus employed.—The apparatus used for collecting the rainfall with its suspended and dissolved impurity, is a large circular enamelled iron funnel, having a collecting area of 4 sq. ft., and holding large glass bottles, in which each month's rainfall is stored for examination. The collecting funnels are placed on the ground-level in places free from abnormal smoke and dust, as near as possible to the centre of the town or district, the air of which is to be examined. Before removing the bottles on the last day of each month, the inside of the collecting funnel is washed down with some of the water already collected, a squeegee being used to remove any soot or dust that adheres to the interior of the funnel. The details recorded include volume of water collected, total solids, total soluble matter, total insoluble deposit, tarry matters, non-tarry carbonaceous matter, sulphates, chlorides, ammonia, and lime.

In response to the circular letter sent out by the London Committee early in 1913, the Health authorities of 21 towns and cities agreed to join in the observations. In some of these places several gauges will be employed at different centres. Owing to some delay, however, in obtaining the necessary supply of large enamelled gauges, only London was equipped with three gauges when the observations were started in March last.

Table I.

Fall of solid matter.

Name of town or city.	Metric tons per sq. km. in August.	
	Total solids.	Tar, soot, and ash.
Sheffield (Attercliffe)	21·34	14·55
Oldham	19·01	11·67
Bolton	18·02	9·12
Liverpool	15·87	8·23
Manchester (School of Technology)	14·33	9·26
Birmingham	14·20	10·10
Newcastle	13·44	10·52
Paisley	12·82	6·83
Kingston, Hull	11·70	6·89
Sheffield (average of four stations)	10·59	6·30
York	8·79	5·69
Leith	8·78	6·13
Greenock	8·64	4·36
Manchester (average of six stations)	7·99	4·10
London (average of two stations)	7·94	3·88
Exeter	6·21	3·35
Malvern	2·01	·71

Table I. contains a summary of the more important figures for August, the last month for which the reports have been published. The difference between the figures in col. I. and col. II. gives the soluble portion of the solid matter brought down with the rainfall. The results in Table I. are expressed as metric tons per sq. km.; they must therefore be multiplied by 2·56 to obtain the soot and dust fall in tons per square mile, which is the form in which the results of earlier investigations have been expressed. If this calculation is made for the worst and best results given in Table I., it appears that Sheffield (Attercliffe) had a total soot and dust-fall in August equal to 640 tons per sq. mile per annum, though the average for the whole city (four stations) was only 317 tons. Malvern had a fall of less than one-fifth this amount, or 60 tons per sq. mile per annum.

The constituents of the solid matter which falls upon our towns and cities are of great interest, and in Table II., the totals given in the second column of Table I. are separated to show the relative proportions of tar, soot, and ash. It will be seen that the relative position of the towns is slightly altered in this table, and that Sheffield (Attercliffe), Oldham, Newcastle, Birmingham, Manchester, Bolton, and Liverpool in the order given are the dirtiest towns, when judged by their respective falls of what is generally known as "soot."

Table II.

Tar, soot, and dust fall.

Name of town or city.	Metric tons per sq. km. in August.			
	Tar.	Carbon.	Ash.	Total.
Sheffield (Attercliffe)	·48	3·45	10·62	14·55
Oldham	·16	3·25	8·26	11·67
Newcastle	·12	3·87	6·52	10·51
Birmingham	·10	2·60	7·50	10·20
Manchester (Technical School)	·07	3·23	5·93	9·23
Bolton	·20	2·94	6·15	9·29
Liverpool	·08	1·63	6·52	8·23
Kingston, Hull	·08	3·26	3·55	6·89
Paisley	·11	2·57	4·15	6·83
Sheffield (average)	·47	1·24	4·59	6·28
Leith	·10	1·76	4·27	6·13
York	·11	1·89	3·67	5·67
Greenock	·03	1·64	2·69	4·36
Manchester (average)	·04	1·66	2·38	4·08
London (average)	·03	1·52	2·32	3·87
Exeter	·03	1·08	2·25	3·36
Malvern	·01	·25	·45	·71

London may be regarded as possessing a standard of atmospheric cleanliness and purity, to which the northern industrial cities and seaports might strive to attain.

The Pittsburgh inquiry.—From a summary of the results of the inquiry into the losses arising from smoke in Pittsburgh, as given in Bull. No. 4 published by the Mellon Institute, it appeared that the total loss was estimated at £1,998,950 per annum. A report on the meteorological aspect of the smoke problem signed by Prof. H. H. Kimball, of the U.S.A. Weather Bureau, is given in Bull. No. 5. A number of papers on the effects of smoke and soot on building materials are collected in Bull. No. 6, edited by Dr. R. C. Brenner, the chief chemist of the commission. The effects of the soot in smoke on vegetation are dealt with in Bull. No. 7, which is a record of experiments carried out by J. F. Clevenger in certain public parks of Chicago, and in Pittsburgh and its environs.

Engineering aspects.—Bull No. 8, the last published, deals with the engineering aspects of the smoke problem in Pittsburgh.

The contents of this bulletin include descriptions of all the different forms of furnace used in Pittsburg for steam-raising purposes, and it gives the following rules for abating smoke and increasing the efficiency of hand-fired furnaces:—1. Fire evenly and regularly. 2. Fire moderate amounts of coal at a time, and place the coal where it is needed. 3. Keep the fire clean, even, and bright all over; do not allow it to burn into holes or thin spots. 4. Break up the lumps and have the coal as nearly as possible uniform in size. Do not fire any lumps larger than a man's fist. 5. When a fire has burned into holes do not throw green coal on the bare grates, but push incandescent fuel into these spots before firing. 6. Regulate the draft and air supply to suit the fire. 7. Watch the condition of the fire and the steam-gauge together. Do not fire large quantities of coal. 8. Do not level or stir the fires unless absolutely necessary, and then use the utmost care. 9. Do not allow ashes and clinkers to accumulate on the side or bridge walls, as this cuts down the effective grate area, and causes other troubles. 10. Do not allow too long intervals between firings. A series of photographs with which the bulletin is illustrated goes far to support the view that Pittsburgh must be considered one of the smokiest and dirtiest cities in the world. (See also this J., 1914, 499.)

Portable apparatus for measuring the electric conductivity of saline solutions. Saviron. *See* XXIII.

Erratum.

Page 1110, col. 1; l. 23 from bottom *for* "capable" *read* "incapable."

Patents.

Collecting and discharging solid matter when pumping liquids [sewage] containing same; Means for ——. R. H. L. Pennell, Khanka, Egypt, and J. Orten Boving, London. Eng. Pat. 21,374, Sept. 22, 1913.

The sewage on its way to the pump passes into a sump through a trap which retains the solid matter. When the sump is full the clear liquid from the delivery of the pump is passed through the trap in the reverse direction and carries forward the solid matter which is thus transported without having to pass through the pump.—W. H. C.

Sludge or solid matter recovered from sewage; Apparatus for drying ——. A. B. Ogden, Manchester. Eng. Pat. 6260, March 12, 1914.

A drying chamber for the sludge is heated by means of steam introduced into the space below the false bottom of the chamber; the steam pipe, which is perforated extends across one end of this space, a drainage channel being provided at the other end. The interior of the chamber is also supplied with a current of air which has been heated by passing through pipes arranged in the flue of the boiler furnace; this flue extends across one end of the chamber, along the side, and then across the other end. The wagons containing the sludge may be run into a space at the heated side of the chamber so that a preliminary drying of the sludge is attained.—W. P. S.

Sewage disposal and water purification apparatus. A. T. Nabstedt, New York. U.S. Pat. 1,115,857, Nov. 3, 1914; date of appl., March 2, 1914.

A settling tank, provided with the usual outlet for the effluent, is situated above a sludge tank, the two being connected by a channel of relatively small cross-section. Means are provided for closing this channel and for maintaining the pressure in the sludge tank equal to the head of liquid in the settling tank. A number of settling tanks may be arranged above one sludge tank.—W. P. S.

Water and other liquids; Apparatus for effecting the sterilisation of —— by ozonation or the like. E. L. Joseph, London. Eng. Pat. 25,503, Nov. 7, 1913.

The water is passed through a centrifugal or rotary pump, to which is also admitted a supply of ozonised air, and then delivered into a tank through a pipe extending to the bottom of the same. The air is dried by passing through a refrigerating apparatus before it enters the ozonising apparatus. (Reference is directed to Eng. Pats. 2707 of 1881, 9741 of 1899, 20,750 of 1905 and 16,128 of 1908; this J., 1900, 369, 1906, 1114; 1909, 742).—W. P. S.

Fluids; Apparatus for the sterilisation of —— [by ultra-violet rays]. W. R. Walkley and Tubex Engineering Co., Ltd., London. Eng. Pat. 14,689, June 18, 1914.

The liquid is passed as a thin film over the inner surface of corrugated plates which are curved so as to form a cylindrical vessel; lamps emitting ultra-violet rays are suspended inside this cylinder. The plates may be curved in various shapes.—W. P. S.

Water; Process of removing oxygen from ——. R. Gans, Berlin-Grunewald, Germany. U.S. Pat. 1,117,831, Nov. 17, 1914. Date of appl., Sept. 15, 1913.

See Fr. Pat. 462,446 of 1913; this J., 1914, 331.—T. F. B.

Sewage and the like; Treatment of ——. N. Testrup, Assignor to Wet-Carbonizing, Ltd., London. U.S. Pat. 1,116,953, Nov. 10, 1914. Date of appl., Feb. 7, 1912.

See Eng. Pat. 3247 of 1911; this J., 1912, 601.—T. F. B.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Lloyd's reagent; Precipitating alkaloids by ——. *Preliminary note.* S. Waldbott. J. Amer. Chem. Soc., 1913, **35**, 837—838.

This reagent is essentially hydrous aluminium silicate derived from fuller's earth, and it has the property of precipitating alkaloids completely from neutral or acid solutions thereof. The alkaloid may be recovered by treatment with a base and an alkaloidal solvent. The reagent as examined by the author had the following composition: H_2O, 17·41; SiO_2, 55·50; Al_2O_3, 9·82; Fe_2O_3, 14·18; CaO, 1·58%. Heating the material to about 130° C. did not destroy its power, but a red heat expelled water, and rendered the reagent inert. When the reagent is exhausted with hydrochloric acid, the residual earth is still effective. Neither nitric acid nor *aqua regia* impair the activity of the reagent. After removal of the alkaloid from the reagent, the residual earth retains its full effect. A jelly is obtained difficult to filter and slow to settle; it is precipitated readily by adding an acid, or an alkaloidal salt. In drying, the jelly shrinks to a very small bulk; conversely, the solid expands remarkably in contact with water. The jelly precipitates inorganic salts also, *e.g.* barium chloride, lead acetate, zinc sulphate, etc. Clearly, the phenomenon is one of colloidal chemistry. It was found that colloidal silicic acid, or colloidal arsenious sulphide precipitate quinine sulphate. (See also this J., 1913, 161, J. U. Lloyd.)

Morphine and strychnine; Precipitation of ——. H. M. Gordin and J. Kaplan. Amer. J. Pharm., 1914, **86**, 461—464.

Attempts were made to shake out morphine from its aqueous solution with a mixture of alcohol and chloroform after saturating with potassium carbonate. The solvent separated well but the amount of morphine found by titration after removing the solvent, exceeded the amount originally taken by 2 to 15%, even after washing the residue with a saturated aqueous solution of morphine to remove traces of potassium carbonate. Morphine is completely precipitated by Lloyd's reagent (see preceding abstract) from acid solution. 90% of the morphine present can be extracted from the dried precipitate by boiling ammoniacal methyl alcohol. Strychnine is also completely precipitated by Lloyd's reagent. The precipitate is almost tasteless and is only slowly decomposed by shaking repeatedly with ammonia and chloroform. It behaves physiologically like strychnine diluted with an inert substance but it cannot be decomposed into free alkaloid outside the organism by pepsin in acid solution or by ptyalin or trypsin in ammoniacal solution.—T. C.

Morphine and codeine; Investigation of some derivatives of ——. A. Pitini. Annali Chim. Appl., 1914, **2**, 208—213.

Morphine oxide sulphonic acid, $C_{34}H_{40}O_{15}N_2S_2$, was obtained by Freund (see Herminghaus, Inaug. Diss., Hildesheim, 1914) by the action of acetic anhydride and sulphuric acid on morphine oxide. It yields morphine sulphonic acid, $C_{17}H_{21}NO_7S$, on treatment with sulphur dioxide. Codeine oxide sulphonic acid, $C_{18}H_{21}O_7NS$, and codeine sulphonic acid, $C_{18}H_{20}NO_3SO_3H,2H_2O$, were obtained by Freund and Speyer (Ber., 1911, **44**, 2339) in a similar manner to the morphine derivatives. A better yield of codeine sulphonic acid can, however, be obtained by dissolving codeine oxide sulphonic acid in caustic soda, adding sodium hydrosulphite, and allowing to stand for a short time. Morphine oxide sulphonic acid (sodium salt) and codeine oxide sulphonic acid (potassium salt) proved to be physiologically inactive, whilst morphine sulphonic acid and codeine sulphonic acid (sodium salts) were less toxic than the alkaloids themselves but produced similar effects, and hence may prove useful therapeutically. The codeine derivatives behave like the alkaloid itself with Frohde's reagent, and with a mixture of concentrated sulphuric acid and formaldehyde, giving a green coloration changing to blue with the former, and a blue coloration with the latter. The reactions of the morphine derivatives are different from those of the alkaloid, morphine, morphine sulphonic acid and morphine oxide sulphonic acid giving respectively a violet, a green, and a green coloration slowly becoming bluish with Frohde's reagent, and a reddish purple changing to violet, a green, and a violet coloration with sulphuric acid and formaldehyde.—A. S.

Aminopyridines: Pharmacological study of ——. *I. α-Aminopyridine and its acetyl derivative.* A. Pitini. Annali Chim. Appl., 1914, **2**, 213—217.

To prepare α-aminopyridine, quinolinic acid, $C_5H_3N(COOH)_2$ was converted into its anhydride by boiling with acetic anhydride and the anhydride was dissolved in benzene and treated with dry ammonia gas. The ammonium salt of the amide of quinolinic acid was thus precipitated, and the free acid, $C_5H_3N(COOH)CO.NH_2$, liberated from this by sulphurous acid, was dissolved in dilute caustic soda, treated with sodium hypobromite, heated on the water-bath, and then treated with sulphurous acid, which precipitated α-aminonicotinic acid, $C_5H_3N(COOH)NH_2$, which was converted into α-aminopyridine, $C_5H_4N.NH_2$, by heating to 310° C. Both α-aminopyridine and its acetyl derivative are capable of producing local anæsthesia, the acetyl derivative being somewhat more active in this respect. Aminopyridine is about as poisonous as stovaine, whilst the toxicity of its acetyl derivative is between that of nirvanine and novocaine.—A. S.

Gentian root: Chemical composition of Japanese ——. Y. Asahina and S. Yoda. Yakugakuzasshi, Aug. 1914. J. Pharm. Chim., 1914, **10**, 376—378.

Extraction of the fresh roots of Japanese gentian (*Gentiana scabra* Bunge var. *Buergeri* Maximowicz) with hot methyl alcohol in the presence of calcium carbonate gave a yield of 4·38% of gentianose and 2·3% of gentiopicrin.—F. Shdn.

British Pharmacopœia, 1914; *Analytical processes of the* ——. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 409.

Clove oil. The official sodium hydroxide solution (20 grms. per 100 c.c.) used to determine the eugenol is too concentrated. A 5% solution of sodium or potassium hydroxide gives satisfactory results. *Cinnamon oil.* A flask with a narrow graduated neck should be used as in the determination of eugenol in clove oil. *Lemongrass oil.* The neutral sulphite process recommended for the determination of the citral gives results 4—5% lower than the bisulphite process generally used for the commercial test. *Balsam of Tolu.* The tests are not satisfactory on the whole and the requirement of 25% of total balsamic acids is somewhat high. The residue obtained on evaporating the carbon bisulphide extract seldom crystallises unless the balsam is old. The test for total balsamic acids soluble in water is better carried out on the balsam itself by the process described under "Styrax" as the esters volatilise with the carbon bisulphide to some extent.—F. Shdn.

Essential oils; Cultivation of plants for the production of ——. W. F. Cooper and J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 407.

Clayey ground overlying chalk was manured and dug for three years, after which plants yielding essential oils were grown thereon. From 60 sq. yds. planted with *Lavandula vera* 2200 stalks and blooms and 4500 blooms of the second year's growth were obtained, the total yield of essential oil being 107 grms. or 1·5%. The characters were: sp. gr. 0·909, optical rotation —5°, esters 5·6%, refr. index at 25° C. 1·4710, soluble in 3 volumes of 70% alcohol. The first year's growth of Mitcham lavender from 98 sq. yds. gave 2050 blooms yielding 92 grms. of oil or 4·5%. The characters were: sp. gr. 0·906, optical rotation —8°, esters 17·7%, refr. index 1·4685, soluble in 3 vols. of 70% alcohol. Common thyme grown on 98 sq. yds. of ground gave 77 lb. yielding 0·106% of oil with the characters: sp. gr. 0·919, optical rotation —2°, phenols 38%. Lemon thyme yielded 0·08% of oil with the characters: sp. gr. 0·891, optical rotation —10°, aldehydes 18%. 3,839 sq. yds. planted with peppermint gave 4,800 grms. of material in the first year, the yield of oil being 0·49%. The characters were: sp. gr. 0·891, optical rotation —28°, esters 14·0%, alcohols 69·6%, refractive index at 25° 1·4502, soluble in 3 vols. 70% alcohol. 1457 sq. yds. planted with wormwood gave 13,550 grms. of material in the first year yielding 0·043% of oil with sp. gr. 0·926, refractive index 1·4572, and soluble in 3 vols. of 80% alcohol.—F. Shdn.

Citronella: Effect of climatic conditions on ——. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5**, 398.

Samples of Burmese citronella oil distilled from grass that had been under water several days owing to floods differed from an oil distilled from dry grass grown in the same locality. The sp. gr. was much higher and the geraniol content was reduced by 7—8%. The odour was somewhat disagreeable. The solubility was not affected.—F. Shdn.

Helichrysum saxatile (Moris.): Oil of ——. L. Francesconi and E. Sernagiotto. Gaz. chim. ital., 1914, **44**, II., 419—421.

The yellowish oil, obtained from plants growing at Lanusei, Sardinia, has a pleasant pungent odour, which at great dilution resembles that of the rose. It has the sp. gr. 0·9020, $n_D = 1·4769$, $[α]_D = —11·71$ (in alcoholic solution), and distils chiefly at 240° C., the distillate containing C 79·50 and H 12·11%.—A. S.

Barosma venusta; Volatile oil from the leaves of ——. E. Goulding and O. D. Roberts. Chem. Soc. Trans., 1914, **105**, 2613—2617.

The leaves of *Barosma venusta*, Eckl. and Zeyh., grown in South Africa yielded 2—2·7% of volatile oil the characters of which were: sp. gr. 0·865—0·867 at 15° C.; $α_D$ at 22°—24° C. 0° 47′ to 1° 4′, acid value 5·6, ester value 6·2, ester value after acetylation 55. The composition of the oil was: hydrocarbons, principally myrcene, 43·0%; aldehydes, principally anisaldehyde, 0·5%; phenols 0·2%; methylchavicol 21·4%; alcohols, partly linalool, 14·3%; the remainder consisting of esters and sesquiterpenes. No evidence of the presence of diosphenol was obtained.
—F. Shdn.

β-Phellandrene; Action of alcoholic hydrochloric acid on ——, *and mechanism of the transformation of terpenes by means of acids.* L. Francesconi and E. Sernagiotto. Gaz. chim. ital., 1914, **44**, II., 456—462.

By the action of cold alcoholic hydrochloric acid on β-phellandrene there is produced, in addition to an oily hydrochloride, the solid dihydrochloride of α-terpinene, m.pt. 51—52° C. The action of acids on other terpenes is recapitulated and it is pointed out that all other mono- and bi-cyclic terpenes in which the side chain is in the para position of the hexamethylene ring are capable of isomerisation into α-terpinene by the action of mineral acids.
—A. S.

Alkylidenehydrazines: Catalytic decomposition of ——. *Hydrocarbons obtained from citral and citronellal.* N. Kijner. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1779—1787. Bull. Soc. Chim., 1914, **16**, 337—339.

The hydrocarbon, $C_{10}H_{18}$, obtained by decomposing the compound of citral and hydrazine (see this J., 1912, 46) consists of a mixture of limonenic and terpinolenic hydrocarbons, the former being in the larger proportion. The limonenic hydrocarbon boils at 162°—163° C. at 760 mm., has the sp. gr. 0·7677 at 20°/0° C., and $n_D = 1·4422$. The terpinolenic hydrocarbon boils at 163°—165° C. at 760 mm., has the sp. gr. 0·7699 at 20°/0° C., and $n_D = 1·4439$, and when oxidised with permanganate yields acetone and the hydrocarbon boiling at 162°—163° C. The hydrobromide of the limonenic hydrocarbon, $C_{10}H_{20}Br_2$, when boiled with aniline yields the terpinolenic form, but when decomposed by boiling with alcoholic potassium hydroxide yields an unsaturated alcohol, $C_{10}H_{19}OH$, boiling at 190°—195° C. Treatment with oxalic acid converts this into linaloolene, $C_{10}H_{18}$, b.pt. 166°—168° C. at 748 mm., sp. gr. 0·7872 at 20°/0° C., and $n_D = 1·5000$. Reduction of the limonenic hydrocarbon by Sabatier's method at 150° C. yields dimethyl-2·6-octane, $C_{10}H_{22}$, which when purified boils at 161°—162° C. at 772 mm., has the sp. gr. 0·7399 at 20°/0° C., $n_D = 1·4146$, and is optically inactive. The corresponding dextro-rotatory dimethyloctane is obtained by reducing the hydrocarbon obtained from citronellal with hydriodic acid, and its characters are: b.pt. 159°—159·5° C. at 742 mm., sp. gr. 0·7313 at 20°/0° C. $n_D = 1·4110$, and $[\alpha]_D = +1·75°$. The hydrocarbon, $C_{10}H_{20}$, obtained from citronellal, when reduced by Sabatier's method at 170° C. gives decane, b.pt. 160°—161° C. at 772 mm., sp. gr. 0·7301 at 20°/0° C., $n_D = 1·4109$, and $[\alpha]_D = +6·27°$, and when the hydrobromic acid addition product is decomposed by means of quinoline it yields a hydrocarbon, $C_{10}H_{20}$, b.pt. 164°—164·5° C. at 782 mm., sp. gr. 0·7521 at 20°/0° C., $n_D = 1·4319$ and $[\alpha]_D + 8·59°$.

—F. Shdn.

Camphor as a solvent. N. N. Efrémoff. J. Russ. Phys.-Chem. Soc., 1913, **45,** 1683—1689. Bull. Soc. Chim., 1914, **16,** 183—184.

The results of a thermal and micrographic investigation of mixtures of camphor with various other substances were:—

Second component of mixture.	Eutectic.		Mols. % of camphor held in solid solution by second component.
	M. pt.	Composition, mols. % of second component.	
	° C.		
p-Toluidine	—	42	18
Naphthalene	31·5	43·5	—
Methyl mustard oil (methyl isothiocyanate)	34·2	50	—

Turpentine; Oxidation of the nopinene (β-pinene) in Spanish oil of ——. A. Madinaveitia. Ann. Soc. Espan. Ph. Ch., 1914, **12,** 259—264. Bull. Soc. Chim., 1914, **16,** 785.

Spanish oil of turpentine, b. pt. 155°—156° C., was treated with permanganate and soda (Wallach's process), the product steam-distilled, and the non-aqueous portion of the distillate rectified in a current of carbon dioxide. Oxalic acid and a little sodium nopinate (1·5% as against 5% obtained by Wallach) were obtained, the smaller yield of the latter being ascribed to the existence of less β-pinene in Spanish than in French or American turpentine.

—W. E. F. P.

Nopinic acid; Reaction of ——. B. Dorronsoro and E. Fernandez. Ann. Soc. Espan. Ph. Ch., 1913, **11,** 441—443. Bull. Soc. Chim., 1914, **16,** 300.

The intense colour reaction given by nopinic acid and resorcinol in sulphuric acid solution has already been made known, and on the strength of this it has been stated that nopinic acid is produced by the oxidation of pinene with alkaline permanganate (see preceding abstract). The substance obtained however is merely sodium oxalate, the colour reaction with resorcinol being equally characteristic of oxalic acid, and moreover very sensitive.—G. F. M.

Acetanilide; Preparation of —— in the laboratory. Haussermann. J. Pharm. Alsace-Lorraine, 1914. J. Pharm. Chim., 1914, **10,** 375—376.

A mixture of equal weights of aniline and acetic acid together with 2—3% of zinc chloride is gently boiled under a reflux condenser for 3 hrs., when the whole is poured into water and the acetanilide recrystallised from water. The use of pure aniline in place of the commercial variety obviates the necessity of decolorising with animal charcoal.—F. Shdn.

Chloral. The polymerisation of ——. J. Bœseken and A. Schimmel. Rec. trav. chim. Pays Bas, 1913, **32,** 112—127. Bull. Soc. Chim., 1914, **16,** 50—51.

An immediate polymerisation of chloral to metachloral is produced by the addition of a small quantity of pyridine or sulphuric acid of 10% strength, the transformation being in the latter case almost complete, whilst in the former it is arrested by the absorption of the catalyst by the colloidal metachloral. By the addition of a large quantity of catalyst the equilibrium chloral ⇄ metachloral is displaced completely to the left, an addition product with the chloral being formed in the case of sulphuric acid which on warming dissociates with the liberation of carbon monoxide, hydrochloric acid and tetrachloroethylene. Aluminium chloride forms with chloral a crystalline addition product which dissociates in a similar way. Pyridine does not cause this dissociation of chloral.—G. F. M.

Chloroform; Presence of acetone in commercial ——. B. Dorronsoro and O. Fernandez. Ann. Soc. Espan. Ph. Ch., 1914, **12,** 191—202. Bull. Soc. Chim., 1914, **16,** 672.

Ten samples of commercial, and two of medicinal chloroform gave the reactions of Legal, Claissen, Kutscheroff and Denigès for acetone. The quantitative determination was made by a comparison of the specific gravity with that of known mixtures, or by the formation of the semicarbazide, but neither of these methods was very exact. The best results were obtained by Fuller's process, the formation of the oxime by the action of hydroxylamine hydrochloride, and titration of the liberated hydrochloric acid. The amount of acetone indicated was about 2% lower than by the density method, and varied from 10 to 23%.—G. F. M.

Isopropyl alcohol; Synthesis of ——. Reduction by hydrogen in the presence of aluminium. F. Lavilla Llorenz. Ann. Soc. Espan. Ph. Ch., 1914, **12,** 236—239. Bull. Soc. Chim., 1914, **16,** 631.

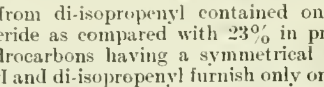
For the preparation of isopropyl alcohol from acetone Sabatier's method is preferable, other processes giving pinacone and condensation products. The action of sodium gives, according to Delacre, 40% of pinacone and only 12% of isopropylalcohol. The addition of aluminium in small pieces to a mixture of acetone and sodium hydroxide produces a slow evolution of hydrogen, and the yield of the alcohol varies from 45 to 50%. At the same time a small quantity of mesityl oxide is formed, but no pinacone.—G. F. M.

Polymerisation; Studies on ——. Diethylenic hydrocarbons. S. V. Lebedeff. J. Russ. Phys.-Chem. Soc., 1913, **45,** 1249—1295. Bull. Soc. Chim., 1914, **16,** 78—80.

All unsaturated organic hydrocarbons are capable of polymerisation under suitable conditions and the velocity of polymerisation may be markedly influenced by catalysts. Aliphatic aldehydes, for example, apparently quite stable under ordinary conditions polymerise rapidly in presence of traces of sulphuric or hydrochloric acids. In most cases cyclic compounds are formed, and the ring always contains an even number of carbon atoms. Polymerisation is indicated by increase of viscosity, which is usually greater the lower the temperature of polymerisation. Isoprene and di-isopropenyl polymerise even below 0° C. The most suitable temperature is 100°—150° C.: at higher temperatures the reactions are more complex. In the author's experiments the hydrocarbons were heated in sealed tubes at 100°—150° C., and the product distilled in a current of hydrogen : the unaltered substance passes over at ordinary pressure and the dimeride at 8—15 mm. pressure, whilst the polymeride remains behind. The higher the temperature the higher is the ratio of the dimeric to the polymeric forms, whilst at constant temperature this ratio remains constant throughout the transformation. The ratio is also affected by the presence of catalysts : when oxygen was removed from the tubes before heating, the product from di-isopropenyl contained only 16·4% of the polymeride as compared with 23% in presence of oxygen. Hydrocarbons having a symmetrical structure, such as divinyl and di-isopropenyl furnish only one dimeric form ; whereas isoprene, which is unsymmetrical, furnishes two, in proportions varying with the temperature. —A. S.

Hydrocarbons of the divinyl series ; Polymerisation of some ——. S. V. Lebedeff and N. A. Skavronskaia. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1296—1331. Bull. Soc. Chim., 1914, **16**, 80—83.

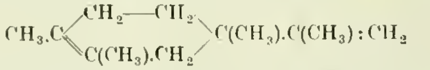
The dimeride of divinyl is ethenylcyclohexene



and the ozonide of the polymeride has the constitution

$$\big(.CH_2.\underbrace{CH.CH}_{O_3}.(CH_2)_2.\underbrace{CH.CH}_{O_3}.CH_2.\big)_x.$$

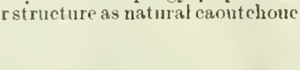
Di-isopropenyl, obtained from pinacone by dehydration in presence of acetic anhydride, was completely converted into an insoluble spongy mass on exposure to light at the ordinary temperature. Polymerisation was also effected at 50°, 100°, and 150° C., and the products separated by distillation (see preceding abstract). The dimeride



is a colourless liquid, b. pt. 205° C. at 750 mm., sp. gr. 0·8597 at 20°/4° C., $n_D = 1·48074$. The polymeride has the constitution

$$[.CH_2.C(CH_3) : C(CH_3).(CH_2)_2.C(CH_3) : C(CH_3).CH_2.]_x$$

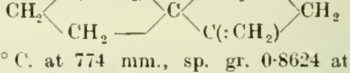
Its ozonide, $C_6H_{10}O_3$, yields acetonylacetone on decomposition with water. Isoprene was prepared by Favorsky's method (hitherto unpublished), the crude product mixed with trimethylethylene, obtained by the decomposition of oil of turpentine, being treated with a cooled solution of hydrobromic acid in acetic acid. From the reaction product amyl bromide was removed by distilling at 52°—53° C. at 100 mm., and the residue was then distilled at 23 mm., the bromide $(CH_3)_2CBr.CH_2.CH_2Br$, passing over at 80°—82° C. This was then heated with powdered potassium hydroxide at 150° C., under a reflux condenser, the isoprene passing over to a cooled receiver. The pure isoprene had the sp. gr. 0·6803 at 20°/4° C., b. pt. 34·5°—35° C., $n_D = 1·42207$. On heating it yielded a viscous mixture of a polymeride and two dimerides, of which one is dipentene, b. pt. 174°—175° C., sp. gr. 0·8454 at 20°/0° C., $n_D^{19·7} = 1·47428$; and the other, dimethyl-1.3-ethenyl-3-cyclohexene-6,



b. pt. 160°—161° C., sp. gr. 0·8331 at 20°/0° C., $n_D^{19·7} = 1·46581$. When isoprene is polymerised at the ordinary temperature, only a white spongy polymeride, having the same molecular structure as natural caoutchouc, is formed. —A. S.

Allene ; Polymerisation of ——. S. V. Lebedeff. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1357—1372. Bull. Soc. Chim., 1914, **16**, 83—85.

When allene was heated at 140°—150° C. in Ipatieff's high-pressure apparatus, the pressure fell in 3 days from 58 to 16 atmospheres, and the hydrocarbon was in part converted into a semi-solid yellowish mass similar to caoutchouc. This polymeride does not resemble those obtained from other allenic hydrocarbons, and possibly the metal of the apparatus exerted a catalytic influence. To avoid this, allene was condensed in glass tubes at —80° C., the air in the tubes was replaced by nitrogen, and they were then sealed and heated in Ipatieff's apparatus, which was filled with hydrogen at 100 atmospheres pressure to prevent bursting of the tubes. After 3½ days at 140° C. one-half of the allene was polymerised. The reaction product was distilled in a current of hydrogen at varying diminished pressures, the approximate yields of the different polymerides being ; dimeride, 5 ; trimeride, 15 ; tetrameride-α, 5 ; tetrameride-β, 22 ; pentameride, 18 ; hexameride, 10 ; and residue (colourless gum-like solid insoluble in the usual solvents), 25%. The dimeride is dimethylene-1.2-cyclobutane, b. pt. 63°—65° C., sp. gr. 0·7698 at 20°/4° C., $n_D^{20} = 1·42317$. It belongs to the divinyl series and polymerises almost completely in a few hours at 150° C., yielding a small proportion of the tetrameride-α of allene but chiefly a transparent solid polymeride. The trimeride,



b. pt. 135° C. at 774 mm., sp. gr. 0·8624 at 20°/4° C., $n_D^{2} = 1·48064$. The tetrameride-α is a colourless liquid having an odour similar to that of turpentine : it boils at 72°—74° C. at 9 mm., sp. gr. 0·8955 at 20°/4° C., $n_D^{20} = 1·53301$. The tetrameride-β, which belongs to the normal type of allenic polymerides, is a colourless liquid with an odour of petroleum : b. pt. 101° C. at 10 mm., sp. gr. 0·9346 at 20°/4° C., $n_D^{20} = 1·52624$. The pentameride is a nearly odourless liquid of b. pt. 131°—132° C., at 10·5 mm., sp. gr. 0·9498 at 20°/0° C., $n_D^{20} = 1·52814$. The hexameride is a nearly odourless liquid, slightly more fluid than glycerol : b. pt. 170° C. at 10 mm., sp. gr. 0·9721 at 20°/0° C., $n_D^{20} = 1·53869$.—A. S.

Hydrocarbons of the diallyl series ; Polymerisation of ——. S. V. Lebedeff. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1372—1373. Bull. Soc. Chim., 1914, **16**, 89.

Diallyl when heated for 8 days at 140°—200° C. remained unchanged, but after 10 days at 250° C., 40% was polymerised : isomerisation also occurred to some extent. The crude reaction product was a mixture of about 15% of a liquid dimeride (b. pt. 97°—98° at 20 mm.) and 85% of a colourless insoluble polymeride resembling caoutchouc. Hexadiene-2.4 when heated at 150° C. yielded a dimeride of b. pt. 86°—90° C. at 20 mm., and after 10 days at 250° C. a dimeride of b. pt. 90°—98° C. (chiefly 96°—98° C.) at 20 mm. ; in both cases the product was different from and more soluble in chloroform than that obtained from diallyl.—A. S.

Hydrocarbons of the divinyl and allene series ; Velocity of polymerisation of ——. S. V. Lebedeff. J. Russ. Phys.-Chem. Soc., 1913, **45**, 1373—1388. Bull. Soc. Chim., 1914, **16**, 89—90.

In the case of divinyl hydrocarbons those in which the terminal carbon atoms of the conjugated system, C : C.C : C, are substituted, polymerise less rapidly than those in which the intermediate carbon atoms are substituted. The velocity of polymerisation increases when ring formation occurs in the chain containing the conjugated system. In a homologous series increase of the mass of the substituents attached to the intermediate carbon atoms of the conjugated system increases the velocity of polymerisation, whilst the reverse is the case if the groups are attached to the terminal carbon atoms. This applies only to aliphatic groups : phenyl, for example, considerably increases the velocity of polymerisation, even when attached to a terminal carbon atom as in phenyl-1-butadiene-1.3. In the case of allenic hydrocarbons, the velocity of polymerisation increases with the mass of the substituting group in a homologous series and the position of the substituents is without influence.—A. S.

Allenic group, C : C : C ; Polymerisation as a means of detecting the ——. S. V. Lebedeff. J. Russ. Phys.-Chem. Soc., 1913, **45,** 1390—1391. Bull. Soc. Chim., 1914, **16,** 90.

ALLENIC hydrocarbons are polymerised almost completely in 1 or 2 days at 150° C., furnishing one or several dimerides of the type,

$$\begin{array}{l} C:C-C \\ C:C-C \end{array}$$

When oxidised with permanganate in aqueous acetone solution these yield substituted succinic acids easy to identify. The dimerides are also characterised by their optical exaltation, the observed molecular refraction being usually greater than the calculated by more than 2, whereas the dimerides of other diethylenic hydrocarbons are optically normal.—A.S.

Methylenecyclopropane (and divinyl). B. K. Merejkowsky. J. Russ. Phys.-Chem. Soc., 1914, **45,** 2072. Bull. Soc. Chim., 1914, **16,** 552—553.

By the action of zinc and 80% alcohol on tetrabromoisobutane a gaseous mixture is obtained which on oxidation with 1% permanganate gives oxalic acid in addition to the ordinary oxidation products of isobutylene. The oxalic acid is derived from methylenecyclopropane which is formed, together with isobutylene, in the first reaction :

$(CH_2Br)_3CBr \rightarrow (CH_2Br)_2C:CH_2$

$$\rightarrow \begin{array}{l} CH_2 \\ CH_2 \end{array}\!\!>C:CH_2 + (CH_3)_2C:CH_2.$$

Methylenecyclopropane is transformed into divinyl when passed over alumina at 350° C. :

$$\begin{array}{l} CH_2 \\ CH_2 \end{array}\!\!>C:CH_2 \rightarrow CH_2.CH:CH.CH_2.$$

—A. S.

Nitrous ether ; Spirit of——. J. C. Umney. Perfumery and Essent. Oil Rec., 1914, **5,** 416—417.

FOR calculating the allowance of drawback on exported spirit of nitrous ether, the percentage of alcohol in the spirit is determined in the Government Laboratory by Thorpe and Holmes' method (this J., 1903, 232). The results obtained by this method are accurate, and are much lower than would be expected from the specific gravity. The loss of alcohol in manufacture amounts to nearly 10% of the quantity used. In the presence of excess of water ethyl nitrite decomposes in a few hours into alcohol and nitrous acid. Solutions should be made in strong alcohol and only diluted when required.—F. SHDN.

Titration of silver in argentum colloidale and argentum proteinicum. A. Korndörfer. Apoth. Zeit., Nov. 11, 1914. Pharm. J., 1914, **93,** 809.

Argentum colloidale.—0·2 grm. is dissolved in 5 c.c. of water, and 5 c.c. of dilute sulphuric acid is added ; the mixture is slightly heated, and subsequently boiled with 10 c.c. of 3% H_2O_2 till it is colourless. On cooling it is diluted with 50 c.c. of water and titrated with *N*/10 NH_4CNS solution, using iron-ammonium-alum as an indicator. One c.c.=0·0108 grm. silver. *Argentum proteinicum.*—0·5 grm. is dissolved in 5 c.c. of water, 5 c.c. of dilute sulphuric acid is added, the mixture slightly heated and subsequently boiled with 15 c.c. of 3% H_2O_2 till the colour is yellow. On cooling, it is diluted with 100 c.c. of water and titrated with *N*/10 NH_4CNS solution.

Drugs and chemicals ; Effect of the War on the supply of ——. Discussion at a meeting of the Pharmaceutical Society, Dec. 8, 1914. Pharm. J., 1914, **93,** 797—804.

PROF. H. G. GREENISH called attention to the progress made during the past 50 years in the cultivation of medicinal drugs (cinchona, coca, ipecacuanha, cloves, vanilla, opium, rhubarb, cubebs, etc.) and stated that the number of medicinal plants cultivated in the various parts of the Empire could be materially extended, and possibly the quality improved as in the case of cinchona. D. Hooper had shown that foxglove and other plants grown in India were equal in efficiency to the European plants. In most cases if the supply of a crude drug became exhausted, a satisfactory substitute could be found.

Mr. E. A. UMNEY dealt mainly with the fluctuation in prices of drugs and essential oils since the outbreak of war and stated that the action of the Government in consultation with the Drugs Advisory Committee, in framing an effective schedule of contraband of war and allowing departure from it only under definite conditions, had done much to prevent clearance of existing stocks and excessive rise of prices. There had not been an actual shortage of any of the essential oils, but supplies of atropine and atropine sulphate and henbane leaves are unavailable at present and the supplies of various other drugs have been considerably restricted. In connection with the position of Russian cantharides, it was pointed out that the new Pharmacopœia includes preparations made from cantharidin, which is produced much more largely from the Chinese than from the Russian flies. The curtailment of the confectionery trade, due to the high price of sugar, has led to a fall in prices of many essential oils used in that trade, notably peppermint and anise oils. The lesson to be drawn from the existing conditions is the necessity for extended cultivation of drugs and aromatic plants throughout the Empire.

Mr. C. A. HILL pointed out that the scarcity of chemicals is not confined to those of foreign origin. Morphine and codeine, for example, the shortage in the supply of which is due to the unusually great demand, are manufactured in England, and now that the supply of Turkish opium is cut off, will be made to a larger extent than hitherto from Indian and Persian opium. Epsom salts, previously imported from Germany, are being made in England from magnesite. There are very considerable stocks of crude potash salts available for the production of pure potassium salts, and a shortage is unlikely since the restricted demand for soap making, fertilisers, etc., due to the high price, will leave a larger supply available for medicinal purposes. Both potash and iodine could be obtained by a resuscitation of the kelp industry, and bromine could, if necessary, be obtained from sea-water. Santonin is obtained from plants grown almost exclusively in Russia under Government control, but the manufacture during the past four years has been entirely in the hands of a German syndicate, and the price has been raised systematically until it reached 115s. per lb. in July last : it has since risen to 220s. owing to the shortage in the supply. Liquid medicinal paraffin was prepared exclusively from Baku petroleum refined at Hamburg. Russia has prohibited the exportation of crude petroleum and the Drugs Advisory Committee has recommended that the Government should endeavour to obtain from the Russian Government a supply of petroleum, which might be refined in the United Kingdom. American and Caucasian petroleums were different in character to Baku petroleum, and might not have the same medicinal effect. Some solvents and reagents not manufactured on a large scale in England, but readily obtained at low prices in Germany are carbonyl chloride, carbon tetrachloride, chlorides and oxychloride of phosphorus, acetic anhydride, acetyl chloride, chloroacetic acids, benzyl chloride, acetoacetic ester, phenylhydrazine, di-, tri-, and tetra-chloroethylene and tetra- and penta-chloroethane (suggested as rubber solvents ; dichloroethylene is used in pharmacy as a solvent for iodine), and ethylene dichloride and ethylidene dichloride (by-products in the manufacture of chloral ; used for the manufacture of lysidine). The production on the large scale of sodium salicylate which will give a colourless aqueous solution is a difficult task, which has not yet been performed in the United Kingdom. The manufacture of synthetic chemicals, except in certain favourable instances, cannot be carried on profitably except on a very large scale, and the industry cannot be established unless security for the future for a sufficient period to admit an adequate return upon capital outlay is ensured.

Mr. F. W. GAMBLE called attention to the dependence upon Continental sources for supplies of laboratory glassware, tubing, scientific instrument and optical glass. The cost of glass tubing has increased 50% and the supply is still short. Having regard to the advantages of Continental countries in respect to raw materials, especially fine sand, England will probably not be able successfully to compete in this industry when normal conditions are restored. Glass of the Jena type does not appear to be made in England, though its manufacture presents no special difficulties. According to analyses made by Prof. Jackson the composition of Jena glass differs essentially from that given in the patent specification covering its manufacture.

Mr. R. R. BENNETT dealt with the supply of chemicals or other medicinal products of which the manufacture is protected by a patent owned by an enemy alien, or which are commonly known by a name in which there exists trade-mark rights owned by an enemy alien. (See also this J., 1914, 1118.)

Prof. A. W. CROSSLEY stated that chloroacetic acid and chlorides of phosphorus could be made in England and that there was no shortage in the supply of acetone.

Mr. E. M. HOLMES considered that the cultivation of medicinal plants in the United Kingdom was not profitable except in cases where there was an enormous demand.

Mr. FINNEMORE said that American liquid paraffin, provided its unpleasant taste were masked by emulsification or by flavouring, could replace the Russian product to some extent, and emulsified soft paraffin might also be used.—A. S.

Camphor production in India. Chamber of Commerce J., Dec., 1914.

THE camphor tree (*Cinnamomum camphora*) has been successfully planted in Burma, Ceylon, and the Federated Malay States. In Burma there are plantations in the upper Chindwin, Myitkyina, Bhamo, and southern Shan States. There are experimental plantations in the Nilghiri Hills and in certain isolated patches of Bombay and Madras. In Ceylon the tree grows only in the more elevated parts; there is a plantation at Hakgala. Great difficulty has always been experienced in getting good seed imported direct from Japan, and there is often wholesale failure to germinate. The seeds sown for the Burma plantations were obtained from Hong Kong. Camphor is also obtained from an evergreen shrub (*Blumea balsamifera*), which is indigenous to the Shan States of Burma. It also grows in the islands of Hainan and Formosa and in South China.

Volatile and essential oils. Board of Trade Bulletin No. 100.

MAY be obtained from the Board of Trade, Commercial Intelligence Branch, 73, Basinghall Street, E.C.

Report of Chemical and Dyestuffs Committee to New York Section of Amer. Chem. Soc. *See* Trade Report.

PATENTS.

Bacterial preparations and preparations for the treatment of gonorrhœal diseases. C. C. Warden, Los Angeles, U.S.A. Eng. Pat. 22,395, Oct. 4, 1913.

BACTERIA such as the *Gonococcus*, *Pneumococcus*, *Meningococcus*, or *Staphyllococcus albus urethræ* are suspended in 0·01 to 0·02% hydrochloric acid, or 0·04% formaldehyde solutions. Such solutions arrest the enzymatic activity of the bacteria without destroying them, and thus prevent autolysis; they may be injected into animals, from which serum is prepared subsequently in the usual manner.—T. F. B.

Hydrogenation; Catalytic ——. M. A. Adam, London. Eng. Pat. 24,815, Oct. 31, 1913.

INTIMATE contact between the reacting materials in the catalytic hydrogenation of liquids, is secured by bubbling the gas from a number of points into a bulk of liquid; coalescence of gas bubbles from adjacent delivery points is prevented by suitable partitions. In one form of apparatus, the hydrogen is supplied vertically through a number of nozzles at the lower part of an upright cylindrical vessel; each nozzle projects into the lower end of a separate vertical tube, open at each end, and these tubes are preferably packed closely together. The tubes may be insulated from each other at the top and bottom, and so converted into a series of electrical heating elements. By a suitable adjustment of the size of the tubes, the gas flow, and the height of liquid in the tubes, the liquid can be treated in the form of a climbing film or a tall column of froth.—T. F. B.

Magnesium salts of acylated aromatic ortho-oxycarboxylic acids. R. Berendes and E. Rietz, Elberfeld, Germany, Assignors to Synthetic Patents Co., New York. U.S. Pat. 1,113,742, Oct. 13, 1914. Date of appl., Jan. 5, 1914.

THE magnesium salts of acylated aromatic *o*-hydroxycarboxylic acids (especially acetylsalicylic acid) are obtained by treating the acid in aqueous suspension with a magnesium compound, *e.g.*, the hydroxide, oxide, or carbonate, evaporating in a vacuum at a low temperature, and washing the crystalline product with acetone. The salts are more readily soluble in water than the acids from which they are derived, and possess similar medicinal properties.—T. F. B.

Alkali metal salts of 3.3′-diamino-4.4′-dioxyarsenobenzene combined with copper and process of making same. P. Ehrlich and P. Karrer, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,117,352, Nov. 17, 1914. Date of appl., Jan. 24, 1914.

SEE Eng. Pat. 1247 of 1914; this J., 1914, 942.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Monobromoquinolsulphonic acids and their conversion into monobromoquinonesulphonic acids. A. Seyewetz and J. Paris. Bull. Soc. Chim., 1914, **15**, 121—125.

THE monobromoquinol obtained by treating quinol dissolved in chloroform and ether with a solution of bromine in chloroform, was sulphonated with acid containing 15% anhydride, at a temperature below 50° C.; a colourless monosulphonic acid was obtained, soluble in water, insoluble in organic solvents, and possessing the properties of a photographic developer. On oxidation with sodium bichromate and sulphuric acid it was converted into the corresponding bromoquinonesulphonic acid, a yellow substance unstable in aqueous solution. An isomeric bromoquinolsulphonic acid, possessing similar properties, was obtained by treating sodium quinonesulphonate with hydrobromic acid below 30° C.; at temperatures above 30° C., the known 2.6-dibromoquinol was produced, proving that the monobromosulphonic acid has the constitution, $OH : OH : Br : SO_3H = 1 : 4 : 2 : 6$. Oxidation of this by chromic acid gave rise to the corresponding bromoquinonesulphonic acid, which is deeper in colour and more unstable in solution than its isomeride.—T. F. B.

PATENTS.

Photographic emulsions. J. H. Christensen, Holte, Denmark. Eng. Pat. 25,419, Nov. 6, 1913.

SILVER bromide or chloride is emulsified in collodion, using a solvent which will produce an impermeable film in which the silver salt is distributed evenly, and not mainly on the surface, as is the case when ether-alcohol is used. The emulsion may be made by treating 12 grms. of collodion silver bromide with 40 grms. of amyl acetate and adding 60 grms. of isobutyl alcohol. When thin films prepared in this way are exposed and developed with glycin, *p*-aminophenol, or similar developers not requiring alkali carbonate, the permeability of the finished film will be greater in those parts which contain reduced silver. Addition to the emulsion of small quantities of certain substances (*e.g.*, 0·1 grm. of benzoic acid to 100 c.c.) facilitates development. If these films are applied to gelatin films supported on glass plates, and then immersed in a solution of a dyestuff, coloured gelatin images may be produced; or if the glass is replaced by metal, and the plates are immersed in an etching liquid, the process can be used to produce photomechanical printing plates.—T. F. B.

Cellulose compound [photographic films]. D. E. Reid, Assignor to Eastman Kodak Co., Rochester, N.Y. U.S. Pat. 1,116,627, Nov. 10, 1914. Date of appl., Jan. 31, 1914.

Photographic films are made of "reverted" cellulose with which is incorporated a "filling" of non oleaginous material which is practically insoluble in water, soluble in alcohols and other solvents miscible with water, practically colourless, has no appreciable effect on the photographic emulsion, and does not react with the chemicals used in photography in such a way as to reduce the transparency of the sheet. Triphenyl phosphate may be used as the filling material.—T. F. B.

Colour photography and kinematography. W. F. Fox, W. H. Hickey, and Kinemacolor Co. of America, New York. Eng. Pat. 552, Jan. 8, 1914.

A negative of a particular object, from which certain colour sensations have been omitted (*e.g.*, taken through a red filter), is superimposed in register on a positive from a negative from which certain other colour sensations have been omitted (taken through a green filter). From this negative and positive a printing negative is made by transmitted light, and from this a positive is made, preferably on a transparent film. This positive is immersed first in an acid solution of a green colouring matter or toning bath such as a solution of a vanadium salt, and then in an alkaline red staining bath. This process is said to produce a picture in "substantially" the colours of the original object. If extra brilliancy in the final print is required, it is desirable to coat the reverse side with an emulsion and to print on it successively, in register, from the two original negatives. Reference is directed in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Act, 1907, to Eng. Pat. 7368 of 1913 (this J., 1914, 503).—T. F. B.

Photographic colour processes. W. F. Fox, W. H. Hickey, and Kinemacolor Co. of America, New York. Eng. Pat. 8728, April 7, 1914.

Two negatives are taken of an object through different light filters (*e.g.*, red and green) and positives are prepared from them on transparent material. The red positive is now printed by transmitted light on a print from the green negative, forming the "colour negative," and the green positive is printed on a print from the red positive producing the "monochrome negative." The "colour negative" is now printed on one side of a sensitised film coated on both sides, and the "monochrome negative" is printed on the other side. After development and fixing, the film carrying the print from the "monochrome negative" is fixed and waterproofed, and the film is immersed in an acid green staining bath and then in a red staining bath. Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 7368 of 1913 (this J., 1914, 503).—T. F. B.

Photographic film. V. Planchon, Assignor to Soc. des Plaques et Papiers Photographiques, A. Lumière et ses fils, Lyons, France. U.S. Pat. 1,116,479, Nov. 10, 1914. Date of appl., May 13, 1907.

See Fr. Pat. 375,433 of 1907 and Addition thereto; this J., 1907, 1029.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Explosives; Specific gravity separation applied to the analysis of mining ——. C. G. Storm and A. L. Hyde. Techn. Paper 78, 1914. U.S. Bureau of Mines. 13 pages.

Chemical analysis of a mixture of salts indicates the quantities of the various ions present, but throws no light on the manner in which these were combined in the original mixture. After removal of nitroglycerin and oily matter by means of ether the finely powdered and dried salts can be roughly separated by treatment in a separating funnel with mixtures of chloroform (sp. gr. 1·49) and bromoform (2·83) of specific gravity between those of the salts expected, most of which, as shown in a table, lie between 1·5 and 2·5.—O. E. M.

Report of Chemicals and Dyestuffs Committee to New York Section of Amer. Chem. Soc. *See* Trade Report.

Patents.

Explosive. W. T. Hoynes, Cleveland, Ohio, U.S.A. Eng. Pat. 6755, March 17, 1914.

Spherical grains of an explosive (*e.g.*, a chlorate explosive) are produced by tumbling dry nuclei of explosive material in the presence of a dust-like explosive of the same nature, and adding a small portion of a moistening liquid in the form of mist. These operations are continued until the spheres are of the required size. The apparatus described comprises an inclined rotating drum into which the dry powdered explosive is fed from a hopper, in the outlet of which is a rotating brush. A suitable quantity of grains of the explosive is placed in the drum, and as this is rotated, the dry powdered explosive is distributed over the grains by rotating the brush, and at the same time water is sprayed in, until pellets of the desired size are obtained.
—G. W. McD.

Explosive compounds. F. R. and J. G. Burrows, Port Arthur, Ontario, Canada. Eng. Pat. 11,582, May 11, 1914.

Ammonium perchlorate (6 parts), potassium nitrate (56), aluminium (18) and paraffin wax (2 parts).—G. W. McD.

Black powder; Aluminium glazed ——. F. Sparre, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,116,944, Nov. 10, 1914; date of appl., Sept. 20, 1913.

Granulated black powder is coated with aluminium.
—G. W. McD.

XXIII.—ANALYTICAL PROCESSES.

Thermostat; A ——, for low temperatures. J. H. Walton, jun., and R. C. Judd. J. Phys. Chem., 1914, 18, 717—721.

The thermostat is capable of working between 0° and —20° C. The primary bath, A, (Fig. 1) of heavy galvanized iron (18 in. square by 14 in. deep) is insulated with a 4-in. layer of sawdust and contains a mixture of ice, salt, and water which is circulated by means of the turbine, C, (1/10 h.p. motor) through a coil, D, passing into the secondary bath, B. The latter contains a mixture of 2 parts of water to 1 part of glycerin and 1 part of alcohol and is insulated in the wooden box, M, by means of a 1-in. layer of felt and a tight cover with an external ¼ in. felt lining. The cold brine is filtered through fine copper gauze at the intake of the pump. The secondary bath contains a screw-shaped stirrer, F. The double

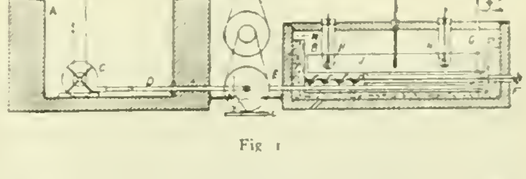


Fig. 1

observation window, J, has an insulating air layer of $\frac{3}{4}$ in. between the panes: this contains the two 4 c.p., 6 volt incandescence lamps, H, H. The lag of the ordinary toluene thermo-regular is avoided partly by using a steel tube, G, filled with mercury, and partly by the slowly rotating wheel, K, which imparts an eccentric motion to the platinum contact wire of the thermo-regulator. Fig. 2 illustrates the automatic cock regulating the influx of cold brine from the primary bath. A wooden wheel, E, is attached to the rod, Y, which operates the cock, Q. The rubber stoppers, S, S, limit the movement of E. The nine-point rocking switch, L, is connected to E by the string, X. In adjusting the thermostat the nut, Z, is loosened so that the consequent opening of the cock brings the temperature to within a fraction of a degree of that required. E is then turned to the right-hand limit and the nut tightened. Rotation of E to the left now causes progressive opening of the cock and consequent inflow of cold brine into the secondary bath. This operation is effected automatically at the proper moment—*i.e.*, when the temperature of the bath becomes too high—through the thermo-regulator throwing the motor, P, into a 110-volt alternating current circuit. The consequent movement of E pulls the rocker of the switch to the left; as soon as the points of the rocker leave the mercury cups on the right the 110-volt circuit is broken: and contact with the mercury cups on the left reverses the fields of the motor. Cold brine now enters the secondary bath till contraction of the mercury in the thermo-regulator breaks the current through the relay and re-starts the motor: E rotates to the right, the cock closes, and the 110-volt current shuts off; and so on. Binding posts or wires bearing the same number in Fig. 2 are connected directly, *e.g.*, 6 on the relay to 6 on the rocker switch. At —12° C. during a run of 6 hours the temperature was constant within 0·03°. The temperature may be kept as low as —25° to —30° C. by using a mixture of ice and calcium chloride in the primary bath; and for high temperatures the latter could be replaced by a boiler generating superheated steam.—J. R.

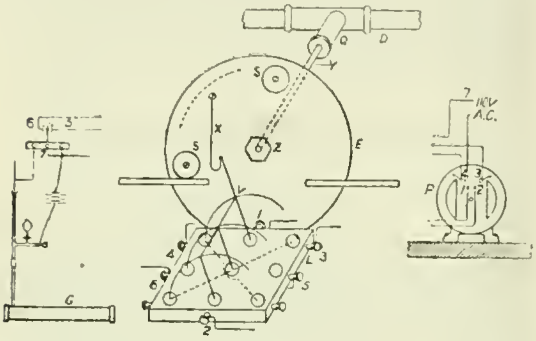

Fig 2

Nickel; The electrolytic determination o ——. W. J. Marsh. J. Phys. Chem., 1914, **18**, 705—716.

Electroanalysis according to Classen's oxalate method is applicable to the determination of tin, but not to that of nickel or cobalt. In the case of nickel the addition of various "dopes" to the solution proved ineffective: small amounts of urea merely resulted in a somewhat more rapid deposition of the metal, while the accompanying carbon deposition was unaffected. Decreasing the size of the anode augmented the tendency of the nickel to deposit as peroxide. The following method gave reliable results: 200 c.c. of a solution containing about 0·2 grm. Ni (as $(NH_4)_2SO_4.NiSO_4.6H_2O$), 15 to 20 c.c. of ammonia (sp. gr. 0·96), and 5 grms. $(NH_4)_2SO_4$, and free from nitric acid, nitrates and chlorides, was electrolysed in a 350 c.c. beaker, using a 10-grm. platinum-wire gauze flag anode (52-mesh and 6 × 4·5 cm.) and a rotating (550—650 revs. per min.) pure copper gauze cathode (50-mesh and 5 cm. high × 3 cm. diam.). With a current of 0·8 amp. ± 0·1 at 3·5 volts ± 0·2, the time required for a determination at the ordinary temperature was about 25 mins. The mean values of 22 experiments were: current, 0·75 amp.; time, 25 mins.; weight of Ni found, 0·1336 grm.; error, +0·0002 grm.—a series of standard determinations being made by the dimethylglyoxime method. The copper-wire gauze cathode was also used successfully in the determination of Cu, Sn, Co, Cd, Bi, Ag and Zn; and for Pb and Mn by deposition as peroxides on a platinum-wire gauze anode. Stiff, twisted copper-wire was used for the stems, and the gauze was riveted with small copper tacks. Such cathodes may be used repeatedly if dipped into nitric acid (1 : 1) for a few minutes after each determination.—J. R.

Tin; Quick method to precipitate —— electrolytically. L. Humphreville. Eng. and Min. J., 1914, **98**, 964.

The tin (0·2—0·3 grm.) is separated as sulphide, dissolved in ammonium sulphide (16 c.c.), 20 c.c. of sodium sulphite solution (40%) added, the liquid diluted to 120 c.c., and electrolysed at 60° C. with a current of 5·5 amp. at exactly 4 volts; cylindrical gauze electrodes are employed, one within the other, and the electrolyte agitated by a stirrer making 600 revolutions per min., the deposition of the metal being effected in 25 mins. Before use, the platinum cathode is either coated with copper and tin in succession or with cadmium alone. The accuracy of the process is sufficient for technical analysis but is impaired by the impurities present in ordinary ammonia solution; for this reason the ammonium sulphide used is prepared by saturating with hydrogen sulphide a solution of ammonia (sp. gr. 0·91) obtained by dissolving the gas (compressed) in water. Sodium sulphite is employed to render the tin solution colourless.—W. E. F. P.

Zirconium; Separation of —— from aluminium. F. Ferrari. Atti R. Istit. Veneto di Sci., 1914, **73**, 445. Annali Chim. Appl., 1914, **2**, 276.

Zirconium can be separated from aluminium by means of cupferron (the ammonium salt of phenylhydroxylamine), which precipitates it quantitatively from acid solution. (See also this J., 1914, 944.)—A. S.

Electric conductivity of saline solutions; Portable apparatus for measuring the ——. P. Saviron. Ann. Soc. Espan. Ph. Ch., 1913, **11**, 495—498. Bull. Soc. Chim., 1914, **16**, 320.

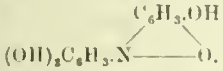
The apparatus has the general arrangement of the Wheatstone bridge with three known resistances. The fourth gap is occupied by a voltameter with separable electrodes, the distance between them being measured on a graduated scale. The voltameter is closed by an ebonite stopper through which passes the insulated stem of the movable electrode, and the whole is protected by a metal case. Conductivities varying between 0·0000670 and 0·00396, representing solutions of potassium chloride containing from 31 to 2·247 mgrms. per litre, can be measured with the apparatus, and its application to the determination of the conductivities of mineral waters has given good results.—G. F. M.

Phenols; Certain colour reactions of the ——. J. G. Carrancio and L. Gomez. Ann. Soc. Espan. Ph. Ch. 1914, **12**, 240—243. Bull. Soc. Chim., 1914, **16**, 672.

The oxidisability of phenols in alkaline solution and the acceleration of the oxidation by metals has wrongfully led to the proposal of certain phenols as reagents for such metals. Copper for example gives a blue colour with phenol and ammonia, but the same colour is produced by nickel and zinc, and, in 24 hours, in the absence of any metal at all. Even the blue coloration of resorcinol with an ammoniacal solution of a zinc salt is produced by nickel, by atmospheric oxygen, and by hydrogen peroxide, and an examination of the absorption spectrum shows that it is the same compound in every case, probably an unstable peroxide.—G. F. M.

Phenols ; Observations on certain colour reactions of the ——. [*Detection of zinc.*] A. del Campo. Ann. Soc. Espan. Ph. Ch., 1914, **12,** 243-247. Bull. Soc. Chim., 1914, **16,** 735—736.

In spite of the researches of Carrancio and Gomez (see preceding abstract) the blue colour reaction produced by the salts of zinc with ammoniacal solutions of resorcinol retains its value from the point of view of the detection of zinc, since it is the only colour reaction of that metal. The coloration is turned to red in the presence of acids, and it is possibly due to the formation of lacmoid,



$$\begin{array}{c} C_6H_3.OH \\ / \quad \backslash \\ (OH)_2C_6H_3.N\text{———}O. \end{array}$$

a condensation accelerated by the catalytic influence of the zinc salts.—G. F. M.

Saturated and unsaturated hydrocarbons ; Separation of mixtures of —— by means of potassium permanganate. S. S. Nametkine. J. Russ. Phys.-Chem. Soc., 1913, **45,** 1423—1429. Bull. Soc. Chim., 1914, **16,** 126.

An exact separation of saturated and unsaturated liquid hydrocarbons (cyclohexane and cyclohexene, normal hexane and hexylene) could not be effected with permanganate, but in the case of gases (propane and ethylene, propane and propylene, trimethylene and propylene) the unsaturated hydrocarbons were removed quantitatively by a saturated permanganate solution, without the saturated hydrocarbons being affected : the error was never more than 0·27%. It is necessary to use a special apparatus, because the permanganate solution attacks mercury.—A. S.

Oxydases ; General reagents for ——. J. Peset. Ann. Soc. Espan. Ph. Ch., 1914, **12,** 220—232. Bull. Soc. Chim., 1914, **16,** 799—800.

Two reagents are employed together, one being colourless but capable of yielding a colour on oxidation (*e.g.*, various leuco-bases etc.) and the other capable of oxidising the first in the presence of an oxydase. As a reagent of the former class, benzidine (in the presence of acetic acid) is very sensitive in the examination of blood ; hydrogen peroxide and sodium perborate are the most satisfactory oxidants.—W. E. F. P.

Viscosity measurement and a new viscosimeter. A. E. Flowers. Amer. Soc. Testing Materials, 1914. [Advance proof.] 52 pp.

The new viscosimeter consists essentially of a jacketed slanting tube mounted upon a rotating horizontal axis. Investigations are described which illustrate the laws of the resistance encountered by a sphere rolling down such a tube filled with a viscous liquid. For a given ratio (r) of diameter of sphere to bore of tube the time to roll a given distance at any given slope increases directly with the viscosity, provided that the angle of slope is chosen so that the motion is controlled by the viscous resistance, *i.e.*, so that the inertia of the liquid displaced offers no appreciable retarding force. For distilled water and aqueous glycerin containing from 34% of glycerol upwards the sine of the angle of slope was chosen as 0·132 and 0·5 respectively : the tube was 30 cm. long with a bore of 2 mm. ; and the diameter of the steel sphere was 1 mm. The value of r is conveniently made 0·5 : a sudden increase in rolling resistance occurs for ratios exceeding 0·75. The absolute viscosity (η) $=K.K\gamma.t$ dynes, where $K=$ a constant depending upon the diameters of the sphere and tube, the angle of slope and the distance covered by the rolling sphere ; $t=$ time of rolling in seconds ; and $K\gamma=$ a factor due to the densities of the materials used $= \dfrac{\gamma s - \gamma m}{\gamma s - 1}$, where γs and γm are the densities in grms. per c.c. of the sphere and the viscous liquid, respectively. The values of $K\gamma$ for Jena normal glass, hard steel, and platinum are represented graphically for values of γm ranging from 0·70 to 1·30. The available methods of measuring viscosity are reviewed, and it is suggested that the use of the present flow-type viscosimeters should be discontinued. Among the advantages claimed for the sphere-and-tube type of instrument are general applicability, *e.g.*, to black oils ; small amount of material needed ; protection from evaporation and from exposure to the room temperature between check readings, which are made by simple reversal of slope ; possibility of use at high temperatures and under pressure ; ready adaptation to very viscous liquids by the use of denser spheres, higher slopes, or, more especially, shorter roll distances ; general simplicity of the apparatus ; and economy in time.—J. R.

XXIV.—MISCELLANEOUS ABSTRACTS.

Glycerinosols of gold. P. P. von Weimarn. J. Russ. Phys.-Chem. Soc., 1914, **45,** 2075. Bull. Soc. Chim., 1914, **16,** 515.

If a solution of auric chloride in anhydrous glycerol be heated to boiling, the bright yellow colour fades and from the moment the solution becomes colourless (formation of aurous chloride), conversion of the gold into a disperse phase begins, glycerinosols of gold having a steel blue colour by transmitted light being obtained. By using very dilute, nearly colourless solutions of auric chloride in glycerol, and suitably regulating the rate of cooling, glycerinosols of colours ranging from pink to blue can be obtained.—A. S.

Colloidal gold solutions ; Immediate coagulation of —— by gold, silver or aluminium foil. P. P. von Weimarn. J. Russ. Phys.-Chem. Soc., 1914, **45,** 2075—2076. Bull. Soc. Chim., 1914, **16,** 516.

On shaking 5 c.c. of a crimson gold hydrosol (prepared by Gutbier's method ; this J., 1914, 888) with pieces of gold, silver or aluminium foil, decolorisation was effected in 3 mins. with the gold, 1 min. with the silver, and in a few seconds with the aluminium. When the crimson hydrosol was left in contact with gold foil, without agitation, it became blue after 15 days. An alcohosol of barium sulphate which had been kept unaltered for 6½ years, showed no change when shaken for 5 mins. with gold foil, but coagulated on the following day. (See also this J., 1914, 670.)—A. S.

Cool flames with ether. A. Leighton. J. Phys. Chem., 1914, **7,** 619—622.

When ether is projected on to a heated surface in a dark room, a cool blue flame which does not char paper is observed, as was first described by Davy and later by W. H. Perkin and others. This is explained as being due to the slow combustion of a mixture of ether vapour heated to, or above, its ignition temperature, with a relatively small amount of air. The same effect is obtained by mixing ether with carbon tetrachloride, or with carbon bisulphide in a dish and applying a match, or by passing carbon dioxide through ether, or through carbon bisulphide, in a narrow cylinder and lighting the issuing gases.—G. H. F.

Oxidation by catalysts; Comparative study of —— of organic and inorganic origin. A. J. Ewart. Proc. Roy. Soc., 1914, B, **88**, 284—320.

Investigation of the oxydase action of salts of Cu, Fe, Cr, Pb, Mn, etc., and of the Na or K salts of ferro- or ferricyanic, phosphoric and chromic acids, shows a close correspondence between them and organic oxydases. The oxydase action may be accelerated by "sensitisers" such as sodium or potassium phosphates or chlorides, which may, for example, enable a peroxydase to work in the absence of a peroxide. Both organic and inorganic oxydases vary from strong to weak, and there is no justification for any real distinction, other than that of degree, between oxydases, peroxydases, and catalases, one and the same enzyme or metallic salt functioning in various ways according to circumstances such as the presence or absence of a sensitiser, attenuation, etc. Strong metallic poisons arrest the action of organic oxydases (apple, potato, etc.) or destroy them, hence they are probably proteins, with or without oxydase metals, in basic or acid combination. The above-mentioned sensitisers and inhibitors (barium chloride, acids) may in some cases with increasing concentration reverse their effects, whilst a substance which is a sensitiser with one oxidant may act as a reducing agent with another (copper sulphate and salt on indigo carmine). The influence of sodium chloride, etc., on plant metabolism may possibly be due to its behaviour as a sensitiser to oxydase action. Anæsthetics retard or inhibit catalase, but not oxydase action. Dried organic oxydases may retain their properties for three weeks; a glycerin extract for five or more months. The oxydases of beetroot and potato are among the strongest plant oxydases, and the nearest analogues are afforded by ferric salts and ferricyanides. Carrot and parsnip oxydase and malt diastase are oxydases of a feebler character.—G. F. M.

Trade Report.

Export prohibitions. Times, Dec. 8, 1914.

The London Gazette, of December 5th, states that the export of extracts for use in tanning is prohibited to all destinations.

Very few, if any, of the extracts used in tanning in this country are home manufactures or products, the goods of this class, which in the past have been sent abroad, having been exported after importation. France, Corsica, the United States of America, Newfoundland, and Turkey are the countries from which supplies are chiefly imported, whether for home use or re-export.

The Swedish Government has prohibited the export of woollen yarn, indiarubber, guttapercha, balata, refined gum, tinned or leaded ironplates, tinplates, copper, raw worked or electrolytic, copper dross, copper plates, copper wire, and of cup-shaped articles for the manufacture of cartridges of copper or brass.

The Danish Government has prohibited the export of malt and vegetable stearines for the manufacture of margarine, of raw material for the manufacture of powder and explosives, hematite iron ore, raw hematite iron, chrome iron, silicic, iron and nickel ore.

Chemicals and Dyestuffs Committee; Report of —— to New York Section of American Chemical Society. Textile Colorist, 1914, 36, 332—334.

Alterations of the tariff law are necessary to introduce the manufacture of explosives, medicinals, chemicals and dyestuffs into the United States. The United States produces sufficient quantities of raw products to supply a self-contained industry, and such an industry could be brought into being if there were a certainty of output in the nature of a demand from home users. To be independent of all foreign nations at all times as regards the supply of explosives, or to protect the textile industries using chemicals and dyestuffs and make them independent of foreign nations, the nation must bear the burden incident to such expansion.

The recommendations of the Committee are: (A) To prevent the unfair underselling alleged to be practised by foreigners in the United States, an effective anti-dumping clause should be adopted. (B) The so-called coal-tar "intermediates" which are the basis of the coal-tar chemical industry, inclusive of explosives, medicinals and dyestuffs, should be assessed one-half of whatever the finished dyes are taxed for tariff purposes; all coal-tar dyes without exception to be taxed alike, namely, 30% *ad valorem* and 7½ cents per pound specific. (C) Changes in the patent laws such as compulsory licensing or compulsory working clauses are wholly ineffective, do more harm than good and should not be attempted.

—G. H. F.

Contraband of War. Revised list. London Gazette Suppl., Dec. 23, 1914.

A new Royal Proclamation gives a revised list of articles which Great Britain will treat as absolute or conditional contraband. This list is in substitution for the one issued on October 29th. Sulphur and glycerin are now taken out of the category of conditional contraband; and several important additions and alterations are made in the schedule for absolute contraband.

The earlier schedule included the following articles under separate headings:—Sulphuric acid, hæmatite iron ore and hæmatite pig iron, nickel ore and nickel ferro-chrome and chrome ore, unwrought copper, aluminium, ferro-silicon, and rubber. In place of these, the new schedule includes the following:—

Ingredients of explosives—viz., nitric acid, sulphuric acid, glycerin, acetone, calcium acetate and all other metallic acetates, sulphur, potassium nitrate, the fractions of the distillation products of coal tar between benzol and cresol inclusive, aniline, methylaniline, dimethylaniline, ammonium perchlorate, sodium perchlorate, sodium chlorate, barium chlorate, ammonium nitrate, cyanamide, potassium chlorate, calcium nitrate, mercury. Resinous products, camphor and turpentine (oil and spirit). Ferro alloys, including ferro-tungsten, ferro-molybdenum, ferro-manganese, ferro-vanadium, ferro-chrome. Tungsten, molybdenum, vanadium, nickel, selenium, cobalt, hæmatite pig-iron, manganese. Wolframite, scheelite, molybdenite, manganese ore, nickel ore, chrome ore, hæmatite iron ore, zinc ore, lead ore, bauxite. Aluminium, alumina and salts of aluminium. Antimony, together with the sulphides and oxides of antimony. Copper, unwrought and part wrought, and copper wire. Rubber (including raw, waste, and reclaimed rubber) and goods made wholly of rubber.

It is further announced that the export of explosives of all kinds and valonia is prohibited to all destinations.

Rudolph Messel, Ph.D., F.R.S.	1914.

† Deceased.

LIST OF COUNCIL, 1913—1914.

President.

Dr. Rudolph Messel, F.R.S., 147, Victoria Street, London, S.W.

Vice-Presidents.

Julian L. Baker, Stainesbury Holt, Kingston Road, Staines.
Sir Hugh Bell, Bart., 95, Sloane Street, London, S.W.
Prof. Marston T. Bogert, Columbia University, New York City, U.S.A.
Dr. Charles C. Carpenter, South Metropolitan Gas Co., 709, Old Kent Road, London, S.E.
Prof. W. Hodgson Ellis, 74, St. Alban Street, Toronto, Canada.
Sir Richard Garton, Southampton Wharf, Battersea, S.W.
Henry Hemingway, 9, Albemarle Mansions, Hampstead, N.W.
Prof. G. G. Henderson, Royal Technical College, Glasgow.
E. Grant Hooper, 16, Royal Avenue, Sloane Square, London, S.W.
Prof. W. J. Pope, F.R.S., Holmesdale, Brooklands Avenue, Cambridge.
Walter F. Reid, Fieldside, Addlestone, Surrey.
Maximilian Toch, 320, Fifth Avenue, New York City, U.S.A.

Ordinary Members of Council.

W. J. A. Butterfield, 66, Victoria Street, London, S.W.
Eustace Carey, The Groves, Grassendale Park, Liverpool.
R. H. Clayton, 1, Parkfield Road, Didsbury, Manchester.
Prof. F. G. Donnan, F.R.S., University College, Gower Street, London, W.C.
Dr. M. O. Forster, F.R.S., 84, Cornwall Gardens, London, S.W.
D. Lloyd Howard, Uphall Works, Ilford, Essex.
Dr. Charles A. Keane, 119, Ladbroke Road, London, W.
Dr. W. Lash Miller, 50, St. Alban Street, Toronto, Canada.
Wm. J. Leonard, 1, Lindfield Gardens, Hampstead, N.W.
G. W. Macdonald, Whitefriars, Rochester, Kent.
N. H. Martin, Northumberland Road, Newcastle-on-Tyne.
J. Miln Thomson, Royal Gunpowder Factory, Waltham Abbey, Essex.

Chairmen and Secretaries of Sections (Ex-officio Members of Council).

Birmingham :
Chairman .. H. T. Pinnock, 11, Fountain Road, Edgbaston, Birmingham.
Secretary .. F. R. O'Shaughnessy, 42, Temple Street, Birmingham.

Canadian :
Chairman .. Prof. R. F. Ruttan, McGill University, Montreal, Canada.
Secretary .. Alfred Burton, 114, Bedford Road, Toronto, Canada.

Liverpool :
Chairman .. Prof. E. C. C. Baly, 14, Sunnyside, Prince's Park, Liverpool.
Secretary .. Dr. Alex. Rule, The University, Liverpool.

London :
Chairman .. Prof. W. R. E. Hodgkinson, 89, Shooter's Hill Road, Blackheath, S.E.
Secretary .. J. H. Coste, Utopia, Gloucester Road, Teddington

Manchester :
Chairman .. Julius Hubner, Linden, Cheadle Hulme, Cheshire.
Secretary .. L. E. Vlies, Belmont, Gowan Road, Alexandra Park, Manchester.

Newcastle :
Chairman .. T. W. Lovibond, West Jesmond House, Newcastle-on-Tyne.
Secretary .. Dr. F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

New England :
Chairman .. S. W. Wilder, 33, Broad Street, Boston, Mass., U.S.A.
Secretary .. Alan A. Claflin, 88, Broad Street, Boston, Mass., U.S.A.

New York :
Chairman .. G. W. Thompson, 129, York Street, Brooklyn, N.Y., U.S.A.
Secretary .. Dr. Parker C. McIlhiney, 7, East 42nd Street, New York City, U.S.A.

Nottingham :
Chairman .. Sir John Turney, Trent Bridge Leather Works, Nottingham.
Secretary .. Dr. H. J. S. Sand, University College, Nottingham.

Scotland :
Chairman .. Dr. Thos. Ewan, Cassel Cyanide Co., Shuna Street, Maryhill, Glasgow.
Secretary .. Dr. G. S. Cruikshanks, Royal Technical College, Glasgow.

Sydney, N.S.W. :
Chairman .. Loxley Meggitt, Wheatsheaf Works, Alexandria, Sydney.
Secretary .. T. U. Walton, Colonial Sugar Refining Co., O'Connell Street, Sydney.

Yorkshire :
Chairman .. George Ward, Millgarth Mills, Leeds.
Secretary .. Thos. Fairley, 17, East Parade, Leeds.

Honorary Treasurer.

Thomas Tyrer, Stirling Chemical Works, Stratford, London, E.

Honorary Foreign Secretary.

Dr. R. Messel, F.R.S., 147, Victoria Street, London, S.W

General Secretary.

Chas. G. Cresswell, Broadway Chambers, Westminster, S.W. (Telegraphic address :—"Induchem," Vic., London; Telephone No., 715, Victoria.)

Editor.

Watson Smith, 34, Upper Park Road, Haverstock Hill, London N.W.

LIST OF MEMBERS.

THE MEMBERSHIP ON FEBRUARY 28TH, 1914 = 4092.

NOTE: "O.M." MEANS ORIGINAL MEMBER.

A

1912. Abady, Jacques, 1, Westminster Palace Gardens, London, S.W., and (Journals) 11, Lyndhurst Road, Hampstead, N.W., Barrister-at-Law, M.Inst.Mech. E.

1912. Abegg, Dr. Fritz, Tottenville, Staten Island, N.Y., U.S.A., Chemist.

1903. Abraham, Herbert, 13, West 89th Street, New York City, U.S.A., Chemist.

1909. Acheson. Dr. Edward G., 5, Chancery Lane, London, W.C., President. Acheson Oildag Co.

1902. Acker, Chas. E., 80, Main Street. Ossining, N.Y., U.S.A., Manufacturer.

1913. Acland. L. H. Dyke, 55, Comeragh Road, West Kensington, W., Analytical Chemist.

1903. Acton, J. Rowland, India Store Depôt, Belvedere Road, London, S.E., Civil Servant.

1911. Acton, Leonard T., c/o Wm. Davies Co., Ltd., 521, Front Street East, Toronto, Canada, Chemist.

1913. Acton, Walter. 9, Trees Park Avenue, Barrhead, Scotland, Works Manager and Chemist.

1912. Adam, G. H., "Lintrose," Malakoff Street, Marrickville. Sydney, N.S.W., Customs Analyst.

1907. Adam, Wm. A., c/o Mander Bros., Wolverhampton, Chemist.

1892. Adams, Arthur, Kelvin House, Edgbaston Road, Smethwick near Birmingham, Science Lecturer.

1911. Adams, E. Bryan, c/o Curtis's and Harvey, Ltd., Explosives Works, Cliffe at Hoo, Kent, Chemist.

1897. Adams, Thos. H., Newtongrange, Manor Road, Borrowash, near Derby, Analyst.

1895. Adamson, G. P., The Baker and Adamson Chemical Co., Easton, Pa., U.S.A., Manufacturing Chemist.

1891. Adcock, S. R., St. Helens Smelting Co., Ltd., Atlas Court, St. Helens, Lancashire, Analytical Chemist.

1901. Addison, Leonard, c/o Messrs. Burt, Boulton, and Haywood, Selzaete, Belgium, Chemist.

1898. Adgate, M., Naugatuck, Conn., U.S.A., Chemist.

1913. Adkins, Linden R., 12, Fenwick Street, Rochester, N.Y., U.S.A., Oil Refinery Chemist.

1896. Adler, Dr. Leon N., Adler Colour and Chemical Works, 100, William Street, New York City, U.S.A., Manufacturing Chemist.

1907. Adley, Geo. S., Storer's Wharf, Poplar, London, E., Varnish Manufacturer.

1888. Adriance, Dr. John S., Williams College, Williamstown, Mass., U.S.A., Analytical Chemist.

1899. Adrot, Léon, 16, Palmer Avenue, Port Richmond, N.Y., U.S.A., Chemist.

1912. Aitken, James. c/o Pratt and Letchworth Co., Brantford. Ontario, Canada, Chemist.

1886. Aitken, J. B., Gerard's Fold Chemical Works, Widnes, Chemical Manufacturer.

1910. Aitken, Dr. J. M., St. Catherine, Bishopton, Renfrewshire, Chemist.

1912. Akers, Noel C., 102, Boulevard, Hull, Lecturer in Chemistry.

1883. Albright, G. S., Bromesberrow Place, Ledbury, Chemical Manufacturer.

O.M. Albright, W. A., 29, Frederick Road, Edgbaston, Birmingham, Chemical Manufacturer.

1906. Alcock, Frank H., 9, Broad Street Corner, Birmingham, Analyst.

1898. Alden, John, Chemical Laboratory, Pacific Mills, Lawrence, Mass., U.S.A., Chemist.

1909. Alén, Dr. J. E., Stadskemistens Laboratorium, Göteborg, Sweden, Public Analyst.

1899. Alexander, D. Basil W., c/o General Petroleum Co., R.F.D. No. 2, Box 52, Los Angeles, Cal., U.S.A., Chemist.

1913. Alexander, Jas., 2208, Allendale Street, Walbrook, Baltimore. Md., U.S.A., Research Chemist.

1900. Alexander, Jerome, c/o National Gum and Mica Co., N.E. cor. 59th Street and 11th Avenue, New York City, U.S.A., Chemist.

1912. Alexander, Walter, National Gum and Mica Co., 59th Street and 11th Avenue, New York City, U.S.A., Secretary.

1883. Alexander, W. T., Crumnock, Eccles, Manchester, Drysalter.

1906. Allan, David, c/o Price's Patent Candle Co., Ltd., Belmont Works, Battersea, S.W., Chemist.

1891. Allan, F. H. Tielke, c/o James S. Kirk and Co., Soap Works, Chicago, Ill., U.S.A., Technical Chemist.

1898. Allan, John, 77, Northen Grove, West Didsbury, Manchester, Chemist.

1909. Allan, Maurice, 103, Burford Road, Nottingham, Soapmaker.

1907. Allard, M. L., c/o Dunlop Tire and Rubber Goods Co., Toronto, Canada, Chemist.

1902. Allbright, Wm. B., 4937, Madison Avenue, Chicago, Ill., U.S.A., Chemical Engineer.

O.M. Alldred, C. H., 8, St. Margaret's Road, Plumstead Common, Woolwich, S.E., Technical Chemist.

1898. Alleman, Dr. Gellert, Swarthmore College, Swarthmore, Pa., U.S.A., Professor of Chemistry.

1903. Allen, Chas. A., Overdale, Sunnyhurst, Darwen, Lancashire, Chemist.

1911. Allen, Harry L., 155, Summit Avenue, Summit, N.J., U.S.A., Chemist.

O.M. Allen, J., 164, Upper North Street, Poplar, E., Manufacturing Chemist.

1913. Allen, Percy T., c/o Partington Steel and Iron Co., Irlam, near Manchester, Coke Ovens Manager.

1893. Allerton, Rt. Hon. Lord, F.R.S., (Journals) Allerton Hall, near Leeds; and c/o W. L. Jackson and Sons, Ltd., Buslingthorpe, Leeds, Tanner.

O.M. Allhusen, A., (Jnls.) W. Russell, Allhusen Works, Gateshead-on-Tyne, Chemical Manufacturer.

1886. Allibon, G. H., The Gables, Deramore Park, Belfast, Ireland, Chemical Works Manager.

1913. Allmand, Dr. A. J., Muspratt Laboratory, The University, Liverpool, Lecturer in Chemistry.

1905. Allpass, Jas., 9, Albert Square, Manchester, Secretary.

1912. Almy, Charles, c/o American Vulcanized Fibre Co., Wilmington, Del., U.S.A., Chemical Engineer

1889. Alpiar, Agop, Smyrna, Asia Minor, Morphia Manufacturer.

1899. Alsop, Wm. K., Ridgway, Pa., U.S.A., Chemist.

1910. Amin, Bhailal D., The Alembic Chemical Works Co., Ltd., Gorwo Road Camp, Baroda, India, Chemical Agent.

1905. Amory, L. H., c/o Messrs. J. Heathcoat and Co., Tiverton, Devon, Lace Manufacturer.

1910. Anderson, Jas. R. V., School of Mines, Bendigo, Victoria, Australia, Lecturer in Chemistry and Metallurgy.

1900. Anderson, Jas. W., Analytical Chemist.

1889. Anderson. Robt. T. R., 42, Roslea Drive, Dennistoun, Glasgow. Technical Chemist.

1894. Anderson, Dr. W. Carrick, 7, Scott Street, Garnet Hill, Glasgow, Consulting Chemist.

1905. Andreae, Dr. E. P., c/o British Glanzstoff Manufacturing Co., Ltd., Flint, North Wales, Chemist.
1913. Andrews, Cecil G., 1, Lozells Street, Birmingham, Chemist.
1907. Andrews, Chas. T., 14a, Finsbury Square, London, E.C., Chemist.
1889. Andrews, Dr. Clement W., c/o The John Crerar Library, Wabash Avenue and Washington Street, Chicago, Ill., U.S.A., Librarian.
1912. Andrews, Ernest R., "Nutfield," Druce Road, Dulwich, S.E., Analytical and Consulting Chemist.
1903. Andrews, Wm. H., 79, Tonawanda Street, Buffalo, N.Y., U.S.A., Manager (Varnish Works)
1913. Andrews, W. O., P.O. Box 2671, Johannesburg, South Africa, Analytical Chemist.
1903. Anfilogoff, N. A., Thames Haven, Essex, Chemist and Petroleum Refiner.
O.M. Angell, J., 6, Beaconsfield, Derby Road, Withington, Manchester, Chemical Lecturer.
1913. Annan, J. G., Elm Cottage, Addiewell, Midlothian, Chief Chemist (Mineral Oil Works).
1892. Annandale, C. J. R., The Briary, Shotley Bridge, Co. Durham, Paper Maker.
1894. Ansbacher, L. A., 527, Fifth Avenue, New York City, U.S.A., Colour Manufacturer.
1913. Anspach, Dr. Richard, Lyckorna, Raynham Avenue, Didsbury, Manchester, Dyeworks Manager.
1902. Anthony, John, 82, Bay Street, Toronto, Canada.
1895. Appleby, Prof. W. R., 911, 5th Street S.E., Minneapolis, Minn., U.S.A., Professor of Mining and Metallurgy.
1907. Appleton, Francis H., jun., P.O. Box 815, Franklin, Mass., U.S.A., Rubber Manufacturer.
1894. Appleton, H. A., 63, Rosedale Road, Forest Gate, E., Analytical Chemist.
1900. Appleyard, Geo. H., 1, Carlton Terrace, Hornsea, East Yorks, Chemist.
1905. Appleyard, Jas. R., Royal Technical Institute, Salford, Lecturer.
O.M. Archbutt, Leonard, The Yews, Madeley Street, Derby, Analytical Chemist.
1899. Archdale, T. Henry, 38, Whitebirk, Blackburn, Manager of Tar and Ammonia Works.
1904. Archdale, Wm., Sandhutton, Hill Lane, Blackley, Manchester, Manager of Chemical Works.
1901. Ardagh, Edw. G. R., Faculty of Applied Science, University of Toronto, Canada, Chemist.
1900. Ardern, Edw., Holmleigh, Queen's Road, Urmston, Manchester, Chemist.
1907. Armstrong, Chas. F., c/o Cawnpore Sugar Works, Ltd., Marhourah Factory P.O., Chupra, Sarun, India, Technical Chemist.
1902 Armstrong, Edward E., Pennsylvania Salt Manufacturing Co., Natrona, Pa., U.S.A., Manufacturing Chemist.
1905. Armstrong, Dr. E. Frankland, c/o J. Crosfield and Sons, Ltd., Warrington, Technical Chemist.
1912. Armstrong, Prof. H. E., F.R.S., 55, Granville Park, Lewisham, S.E., Consulting Chemist.
1899. Armstrong, Richard, Saul Street Soap Works, Preston, Lancashire, Soap Manufacturer.
1905. Armstrong, Theodore, 115, Chestnut Street, Philadelphia, Pa., U.S.A., President, Pennsylvania Salt Manufacturing Co.
1905. Arnold, Frank L., 32, School Street, North Woburn, Mass., U.S.A., Chemist.
1899. Arnott, Dr. G. W. Campbell, c/o Fertiliser Manufacturers' Association, 68–70, Fenchurch Street, London, E.C., Agricultural Chemist.
1903. Arnott, J. S., Moros, 42, 2°, Gijon, Spain, Chemist and Metallurgist.
1912. Arny, H. V., 115, West 68th Street, New York City, U.S.A., Teacher and Chemist.
1911. Asahina, Koju, Uyeda Sericulture College, Uyeda, Shinano, Japan, Chemist.
1901. Asano, K., Ashio Copper Mine, Shimozuke, Japan, Consulting Mining Chemist.
1908. Ashbury, J. W., c/o John Brown and Co., Ltd., Laboratory, Atlas Works, Sheffield, Chief Chemist.
1903. Ashley, Frank R., c/o Western Chemical Manufacturing Co., Denver, Colo., U.S.A., Manufacturing Chemist.
1890. Ashton-Bost, W. D. *See* Bost, W. D. Ashton.
1894. Ashworth, Arthur, Fernhill Chemical Works, Bury, Lancs., Chemical Manufacturer.
1908. Ashworth, D. Irving, P.O. Box 38, Wappingers Falls, N.Y., U.S.A., Chemist.
1907. Aspey, Urban, jun., New Station Soap Works, School Close, and (Journals) 11, Neville Street, Leeds, Works Manager and Chemist.
1898. Aspinall, Thos., 34, Chorley New Road, Bolton, Analytical and Manufacturing Chemist.
1900. Aston, Bernard C., Box 40, P.O., Wellington, New Zealand, Chemist.
1891. Atkins, C. E., The Heath, Redbourn, Herts., Chronometer Maker.
1885. Atkinson, A. J., 44, Stuart Street, Cardiff, Analytical Chemist.
1912. Atkinson, F. C., 1864, Gent Avenue, Indianapolis, Ind., U.S.A., Chemist.
1911. Atkinson, James E., The Sheffield Testing Works Ltd., Blonk Street, Sheffield, Analytical Chemist.
1900. Atkinson, Jno. W., Betteravia, Santa Barbara Co., Cal., U.S.A., Manager, Union Sugar Co.
1905. Atteaux, F. E., 176, Purchase Street, Boston, Mass. U.S.A., Dyestuff Importer.
1900. Atwood, Frank W., 216, Milk Street, Boston Mass., U.S.A., Chemist.
1895. Auchterlonie, Wm., c/o Clark Thread Co., Newark, N.J., U.S.A., Dyeworks Manager.
1897. Auger, Chas. L., 425, Park Avenue, Paterson, N.J., U.S.A., Silk Dyer.
1911. Austin, Fred. J., 343, Sixth Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1913. Austin, Wm. L., 113, Church Lane, Charlton, S.E., Analytical Chemist.
1901. Auty, Albert M., c/o John Smith and Sons, Ltd., Field Head Mills, Bradford, Works Chemist.
1902. Avery, D., 461, Barker's Road, Kew, Melbourne, Vic., Australia, Teacher of Chemistry.
1910. Ayers, Gilbert F., Dynamite Factory, Modderfontein, Transvaal, Chemist.
1899. Aylsworth, Jonas W., 223, Midland Avenue, East Orange, N.J., U.S.A., Chemist.

B

1908. Babington, Fred. W., Customs Laby., Customs Dept., Ottawa, Canada, Analyst.
1913. Backus, Cecil F., c/o Atlas Powder Co., Wilmington, Del., U.S.A., Chemist.
1912. Bacon, Charles V., 136, Liberty Street, New York City, U.S.A., Consulting and Analytical Chemist.
1895. Bacon, Nathaniel T., Peace Dale, Rhode Island, U.S.A., Chemical Engineer.
1913. Bacon, Raymond F., Mellon Institute of Industrial Research, The University, Pittsburgh, Pa., U.S.A., Associate Director.
1911. Baddiley, James, c/o Levinstein, Ltd., Crumpsall Vale Chemical Works, Blackley, Manchester, Research Chemist.
1897. Badock, Stanley H., Holmwood, Westbury on Trym, near Bristol, Smelter.
1898. Baekeland, Dr. Leo, Snug Rock, Harmony Park, Yonkers, N.Y., U.S.A., Research Chemist.
1912. Bagley, Fred. P., c/o George H. Morrill Co., Norwood, Mass., U.S.A., Ink Manufacturer.
1913. Bailey, Alan M., Winchester House, Singapore, S.S., Analytical Chemist.
1903. Bailey, Prof. E. H. S., The Library, Kansas State University, Lawrence, Kas., U.S.A., Professor of Chemistry.
1885 Bailey, Edwin M., Almond Hill, Pumpherston, Mid Calder, Scotland, Technical Chemist.
1908. Bailey, Frank W., 25, Lord Street, Glossop, Derbyshire.

1883. Bailey, Dr. G. H., Kinlochleven, Argyll, Scotland, Chemist.
1903. Bailey, Harold J., 10, Park Road, Pendleton, Manchester, Alkali Inspector.
1906. Bailey, Ralph W., 66, Cherry Street, Elizabeth, N.J., U.S.A., Chemist.
1888. Bailey, Dr. T. Lewis, 21, Shavington Avenue, Chester, H.M. Inspector of Alkali Works.
1910. Baillie, Dr. Thomas B., 5, Mossgiel Avenue, Ainsdale, Lancashire, Analytical Chemist (Love Lane Sugar Refinery).
1902. Bain, Prof. Jas. Watson, Faculty of Applied Science, The University, Toronto, Ont., Canada, Chemist.
1911. Bainbridge, Edmund F., c/o American Alkali and Acid Co., Bradford, Pa., U.S.A., Chief Chemist.
1911. Baird, Douglas H., 14, Cross Street, Hatton Garden, London, E.C., Scientific Instrument Maker.
1908. Baird, M. M., 18, Jedburgh Avenue, Rutherglen, Glasgow, Analytical Chemist.
1891. Baird, Wm., c/o Lewis Berger and Sons, Ltd., Homerton, N.E., Technical Chemist.
1895. Baird, W. Raymond, 271, Broadway, New York City, U.S.A., Patent Lawyer.
1890. Bairstow, John, Burley, Queen's Park, Chester, Chemical Works Manager.
1903. Baker, Arthur, Mount Nod, Greenhithe, Kent, Chemist.
1913. Baker, Bertram F., 33, Salford Road, Streatham Hill, S.W., Technical Chemist.
1910. Baker, C. Kerslake, 16, Change Alley, Sheffield, Analytical Chemist.
1902. Baker, Chas. F., Technical College, Sunderland, Lecturer in Chemistry.
1901. Baker, F. Guy Stirling, The Brewery, Chiswell Street, London, E.C., Brewer's Chemist.
1883. Baker, Harry, Epworth House, Moughland Lane, Runcorn, Analytical Chemist.
1904. Baker, John T., c/o J. T. Baker Chemical Co., Phillipsburg, N.J., U.S.A., Manufacturing Chemist.
1892. Baker, Julian L., Stainesbury Holt, Kingston Road, Staines, Brewing and Sugar Chemist.
1909. Baker, Robert P., Ivydene, Bexley, Kent, Technical Chemist.
1886. Baker, Theodore, 705, Du Pont Building, Wilmington, Del., U.S.A., Analytical Chemist.
1910. Baker, Dr. Thos., Westville, Doncaster Road, Rotherham, Chemist and Metallurgist.
1912. Balch, Prof. Alfred W., 416, Huntington Avenue, Boston, Mass., U.S.A., Professor of Biological Chemistry.
1912. Baldracco, Prof. Dr. Giacinto, R. Conceria Scuola Italiana, Corso Ciriê, ang. Via Biella, Turin, Italy, Leather Trades Chemist.
1903. Baldwin, F. H., Bergenport Chemical Works, Bayonne, N.J., U.S.A., Superintendent.
1903. Baldwin, Dr. H. B., 927, Broad Street, Newark, N.J., U.S.A., Chemist (Dept. of Public Health).
1903. Ball, S. F., 289, East 201st Street, New York City, U.S.A., Analytical Chemist.
1912. Ball, Walter W., "Sunnyside," Daybrook, Notts, Dyer.
1889. Ballantyne, Horatio, 75, Chancery Lane, London, W.C., Analytical and Consulting Chemist.
1903. Ballantyne, W. H., 111, Hatton Garden, London, E.C., Patent Agent's Assistant.
O.M. Ballard, Edw. G., 6, Grey Friars, Chester, Alkali Works Inspector.
1910. Baly, Prof. E. C. C., F.R.S., 14, Sunnyside, Prince's Park, Liverpool, Professor of Inorganic Chemistry.
O.M. Bamber, H. Kelway, Outram House, Addiscombe, Surrey, Consulting Chemist.
1894. Bamber, H. K. G. Ingress House, Greenhithe, Kent, Cement Works Manager.
1898. Bamford, Harry, 70, Duckworth Terrace, Bradford, Yorks, Dyer.
1906. Bancroft, John, Wilmington, Del., U.S.A., Bleacher and Dyer.
1913. Banks, A. J., c/o The Ogilvie Flour Mills Co., Ltd., Montreal, Canada, Analyst.
1890. Banks, Jno. H., 80, Maiden Lane, New York City, U.S.A., Mining Engineer.
O.M. Bannister, W., Dunloe, Bramley Hill, South Croydon, Manufacturing Chemist.
1910. Barbary, J. Ewart, "Vellansaundry," Camborne, Cornwall, Explosives Chemist.
1909. Barber, C. Douglas, Great Nelmes, Hornchurch, Essex, Chemist.
1908. Barber, Percy S., The Reform Food Stores, 84, Whitechapel, Liverpool, Chemist.
1901. Barber, Capt. René R., Georgetown, Ont., Canada, Analytical Chemist.
1911. Barclay, Andrew, Oficina Anita, Antofagasta, Chile, Chemist.
1912. Barclay, William R., 50, Upper Albert Road, Meersbrook, Sheffield, Manager of Electroplate Factory and Lecturer in Electro-Metallurgy.
1892. Barden, Alf., Far Bank, Shelley, near Huddersfield, Glue and Size Maker.
1907. Bardorf, C. F., c/o St. Lawrence Sugar Refining Co., Maisonneuve, P.Q., Canada, Chief Chemist.
1902. Barker, Hugh S., 32, Cumberland Avenue, Sefton Park, Liverpool, Laboratory Furnisher.
1913. Barker, J. D., c/o The Sherwin-Williams Co. of Canada, Ltd., Montreal, Canada, Paint Manufacturer.
1912. Barker, Dr. Jonathan, 18, Sandon Street, Liverpool, Chemist.
1905. Barker, Perry, 93, Broad Street, Boston, Mass., U.S.A., Chemist.
1909. Barker, Richard F., Adams, N.Y., U.S.A., Chemist.
1895. Barlow, Clinton W., 104—112, East 25th Street, New York City, U.S.A., Merchant.
1901. Barlow, John J., Broadway, Accrington, Calico Printer's Chemist.
1899. Barlow, Wm., 23, Alton Terrace, Fairfield, Manchester, Analytical Chemist.
1908. Barnes, Alfred, Box 556, Pretoria, Transvaal, Dealer in Minerals.
1906. Barnes, A. G., c/o Hasland Coking Co., Grassmoor Collieries, Chesterfield, Colliery Proprietor.
1914. Barnes, Edward A., c/o The Giant Powder Co., Giant, Cal., U.S.A., Chemical Engineer.
1905. Barnes, F. V., Gas Works, Todmorden, Engineer and Manager.
1884. Barnes, H. J., Phœnix Chemical Works, Hackney Wick, N.E., Manufacturing Chemist.
1884. Barnes, Jonathan, 301, Great Clowes Street, Manchester, Analytical Chemist.
O.M. Barnes, Jos., Green Vale, Westhoughton, near Bolton, Lancashire, Analytical Chemist.
1912. Barnett, E. de Barry, 9, Collingham Road, South Kensington, S.W., Chemist.
1897. Barnett, Robt. E., 9, Virginia Road, Leeds, Headmaster (Leeds Technical School).
1904. Baron, Wm. Briscoe, c/o Vulcan Boiler and General Insurance Co., Ltd., 26, Pall Mall, Manchester, Chemist.
O.M. Barr, J., Dinting Vale, Dinting, near Manchester, Chemical Manager.
1890. Barraclough, Wm. H., Beechwood, Mortomley, near Sheffield, Analytical Chemist.
1890. Barrett, Arthur A., 139, Viale San Martino, Messina, Sicily, Manufacturer of Essential Oils.
1907. Barrett, John H., 111, Adelaide West, Toronto, Canada, Superintendent.
1907. Barrett, Maurice, 9, Roundhay Mount, Leeds.
1912. Barrow, Jas. V., c/o Messrs. W. H. Holmes and Sons, Portland Road, Newcastle-on-Tyne, Works Chemist.
1900. Barrow, Jos., "Woodhey," Malford Grove, South Woodford, N.E., Chemist.
1906. Barrs, Chas. E., 3A, Downshire Hill, Hampstead, N.W., Analyst.
1905. Barry, Eugene, Ayer, Mass., U.S.A., Leather Manufacturer.
1893. Barton, G. E., 227, Pine Street, Millville, N.J., U.S.A., Technical Chemist.
1903. Bartrip, Geo. F., 21, Willow Avenue, Edgbaston, Birmingham, Managing Chemist.
1905. Baruch, Edgar, 805-806, Wright and Callender Building, Los Angeles, Cal., U.S.A., Chemical Engineer.

1910. Barwick, F. W., Chamber of Commerce Testing House, Royal Exchange, Manchester.
1909. Barzano, Carlo, 6, Via Gesu, Milan, Italy, Patent Agent.
1895. Baskerville, Dr. Chas., College of the City of New York, New York City, U.S.A., Professor of Chemistry.
1910. Bassett, Frank L., 73, St. Julian's Farm Road, West Norwood, S.E., Analyst.
1884. Bassett, H., 26, Belitha Villas, Barnsbury, N.
1908. Bassett, Professor Henry, University College, Reading, Prof. of Chemistry.
1899. Bassett, Wm. H., Main Street, Cheshire, Conn., U.S.A., Chemist.
1890. Bate, William, Upton Villa, Hayle, Cornwall, Technical Chemist (National Explosives Co., Ltd.).
1903. Bateman, A. H., Eridge, Shooter's Hill, Woolwich, S.E., Chemist.
1913. Bateman, James T., 34, Bridge Avenue, Hammersmith, W., Engineer and Works Manager.
1912. Bates, D. M., Lewiston Bleachery and Dye Works, Lewiston, Maine, U.S.A., General Manager.
1885. Batty, R. B., Wharncliffe, Erdington, near Birmingham, Nickel Works Manager.
1910. Battye, Horace G., 28, Roman Place, Street Lane, Roundhay, Leeds, Chemist and Works Manager.
1903. Baty, E. J., c/o Thermoelectric Ore Reduction Corporation, Cobden Street, High Town, Luton, Beds, Chemist.
1903. Bauer, Geo. W., 660, Sacramento Street, San Francisco, Cal., U.S.A., Vice-President and Chemist (Hop and Malt Co.).
1910. Baxter, F. Stanley, 119, Albert Street, Regent's Park, London, N.W., Chemist.
1913. Baxter, Harold R., c/o Aktiebolaget J. and G. Cox, Ostrahamingatan 17, Gothenburg, Sweden, Manager (Glue Works).
1898. Baxter, John G., Glenarm, Lennox Avenue, Gravesend, Kent, Chemist.
1912. Bayley, Francis P., c/o F. S. Bayley, Clanahan, and Co., 79, Mosley Street, Manchester, Chemical Merchant.
1911. Bayliss, Thos. R., Belmont, Northfield, Birmingham, Mechanical Engineer and Managing Director.
1908. Bayly, Percival G. W., Mines Dept. Laby., Spring Street, Melbourne. Victoria, Government Metallurgical Chemist.
1897. Beadle, Alec A., Donington Dene, Newbury, Berks, Electro-Chemist.
1886. Beadle, Clayton, Oakbank, Lansdown Road, Sidcup, Kent, Consulting Chemist.
1911. Beard, Stanley D., Lederle Antitoxin Laboratories, Pearl River, N.Y., U.S.A., Biological Chemist.
1907. Beardsley, Dr. Alling P., 165, Minerva Street, Derby, Conn., U.S.A., Chemist (New Haven Gas Co.).
1909. Bearpark, Arthur F., P.O. Box 497, Durban, South Africa, Works Manager.
1908. Beasley, Fred. G., 44, Green Street, Smethwick, near Birmingham, Metallurgical Chemist.
1905. Beasley, Jno. K., c/o The Borneo Co., Kuching, Sarawak, Metallurgical Chemist.
1897. Beaver, Chas. J., Rangemoor, Crescent Road, Hale, Cheshire, Chemist.
1905. Beckers, Dr. Wm., 105, Underhill Avenue, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1909. Becket, Fredk. M., 31, Sugar Street, Niagara Falls, N.Y., U.S.A., Chief Metallurgist, Electro Metallurgical Co.
1912. Beckett, Dr. E. G., Sylva, Caledonia Road, Saltcoats, Ayrshire, Analytical Chemist.
1899. Bedford, Alf. C., 26, Broadway, New York City, U.S.A., Chemical Merchant.
1891. Bedford, Chas. S., Rocella, Weetwood, Headingley, Leeds, Manufacturing Chemist.
1911. Bedforth, G. E., Aspley Dyeware Mills, Huddersfield, Works Chemist.
O.M. Bedson, Prof. P. Phillips, Armstrong College, Newcastle-on-Tyne, Professor of Chemistry.
1901. Beevers, Clifford J., 12, Parish Ghyll Road, Ilkley, Yorks, Analyst.
1899. Behr, Dr. Arno, Chemist.
1903. Behrend, F., 54, Front Street, New York City, U.S.A., Importer of Chemical Stoneware.
O.M. Beilby, Dr. George T., F.R.S., 11, University Gardens, Glasgow, Chemical Engineer.
1912. Belaiew, Captain Nicolai, Chem. Laby., Michael Artillery Academy, St. Petersburg, Russia, Lecturer in Metallurgy and Chemistry.
1906. Belden, A. W., c/o Jones and Laughlin Steel Co., Aliquippa Works, Woodlawn, Pa., U.S.A., Coke Expert.
1884. Bell, Sir Hugh, Bart., Middlesbrough-on-Tees, Soda and Iron Manufacturer.
1900. Bell, Hugh P., c/o Bank of Montreal, Toronto, Canada, Chemist.
1886. Bell, J. Ferguson, Derby Gas Light and Coke Co., Derby, Gas Engineer.
1907. Bell, Marcus, Defence Dept., Melbourne, Victoria, Chemist.
1905. Bell, Miss M. M., Tulane University Library, New Orleans, La., U.S.A., Librarian.
1903. Bell, P. Carter, Millburn, N.J., U.S.A., Chemical Manufacturer.
O.M. Bendix, D., 371, Romford Road, Forest Gate, E., Managing Chemist, British Alizarin Co., Ltd.
1897. Benfey, Dr. Hans, 65, Birchfields Road, Rusholme Manchester, Manufacturing Chemist.
1907. Bengough, Guy D., St. John's Cottage, Chester, Lecturer in Metallurgy.
1903. Benham, Keith, The Woodlands, Rowley Park, Stafford, Analytical and Consulting Chemist.
O.M. Benjamin, Dr. M., Smithsonian Institution, Washington, D.C., U.S.A., Consulting Chemist.
1899. Bennett, Alex. H., Via Giuseppe La Farina, Messina, Sicily, Chemist.
1907. Bennett, H. Garner, 10, Shaftesbury Villas, Beverley, Yorks, Leather Chemist.
1902. Bennie, P. McN., P.O. Box 29, Niagara Falls, N.Y., U.S.A., Consulting Chemist.
1909. Benson, George F., Edwardsburg Starch Co., Cardinal, Ontario, Canada, President and Managing Director.
1906. Benson, Richard W., c/o Geo. Cradock and Co., Wakefield, Yorks, Analytical Chemist.
1901. Bentley, Wm. H., 12, Cromwell Terrace, Irlam, near Manchester, Technical Chemist.
1890. Bentz, Ernest, 30, Manley Road, Whalley Range, Manchester, Technical Chemist.
1913. Benzian, Dr. Rudolf, Hohe Bleichen 34, Hamburg, Germany, Assayer and Merchant.
1912. Bergius, Dr. Friedrich, Parkstrasse 1, Hannover, Germany, Privatdozent.
1912. Beringer, C. R., Magyar Onmüvek, Nagyteleny, Hungary, Assayer.
1884. Beringer, J. J., Basset Road, Camborne, Cornwall, Metallurgist.
1893. Berk, Fred. W., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1907. Berk, Paul F., 1, Fenchurch Avenue, London, E.C., Chemical Manufacturer.
1908. Berlinerblau, Dr. Joseph, 8, Szpitalna Street, Warsaw, Russian Poland, Industrial Chemist.
1900. Bermingham, Jno., jun., 417, Mills Building, San Francisco, Cal., U.S.A., Superintendent.
1889. Bernard, Jas., jun., c/o Parry and Co., P.O. Box No. 12, Madras Presidency, India, Chemical Works Manager.
1897. Berry, Albert E., Abbotsleigh, Wanstead, Essex, Works Manager.
1911. Berry, Arthur G. V., c/o Messrs. B. and R. Redwood, 4, Bishopsgate, London, E.C., Analyst.
1906. Berry, Arthur J., 14, Regent Street, Cambridge, Chemist.
1883. Berry, E. E., Bordighera, Italy, and (Journals) c/o C. H. Grinling, 17, Rectory Place, Woolwich, S.E., Technical Chemist.
1913. Berry, Prof. R. A., The Agricultural College, Blythswood Square, Glasgow, Prof. of Agric. Chemistry.
1903. Berry, W. G., 329, West 83rd Street, New York City, U.S.A., Chemist.

1909. Beskow, K. J., Södra Storgatan 19, Helsingborg, Sweden, Head Engineer.
1886. Best, Dr. T. T., Hardshaw Brook Chemical Works, St. Helens, Lancashire, Technical Chemist.
1901. Betts, Anson G., Stackhouse, N.C., U.S.A., Chemist.
O.M. Bevan, E. J., 4, New Court, Lincoln's Inn, London, W.C., Public Analyst and Consulting Chemist.
1900. Bevan, Jno. W., Morriston Spelter Works, Morriston, R.S.O., Glamorgan, Manager of Metallurgical Works.
O.M. Beveridge, Jas., Springfield House, Chatham, N.B., Canada, Pulp and Paper Manufacturer.
1909. Bewick, R. M., "Lynton," Park West, Heswall, Cheshire. Traveller.
1909. Beynon, Donald E., 80, Hogarth Avenue, Toronto, Canada. Chemist.
1898. Bhattacharyya, Haripada, Gun and Shell Factory, Ishapore, Bengal, India, Chemist.
1896. Bibby. John, c/o J. Bibby and Sons, Formby Street, Liverpool, Chemist.
O.M. Bickerdike, W. E., Bryer's Croft, Wilpshire, near Blackburn, Manufacturing Chemist.
1907. Bickerstaffe, Robt., c/o Thomas and Green, Ltd., Soho Mills, Wooburn Green, S.O., Bucks., Chemist.
1903. Bierwith. L. W., c/o Du Pont Powder Co., Haskell, N.J., U.S.A., Civil Engineer.
1910. Bigelow, Chas. A., c/o Pluto Powder Co., Ishpeming, Mich., U.S.A., Superintendent.
1912. Bigelow, Edward P., Mellin's Food Library, 221, Columbus Avenue, Boston, Mass., U.S.A., Chemist.
1884. Biggart, J. Wm., 29, Cathcart Street, Greenock, Scotland, Analytical Chemist.
1891. Biggart, Wm. L., Rossarden, Kilmalcolm, Scotland, Public Analyst.
1911. Biggins, J. E., c/o Gulf Refining Co., Port Arthur, Texas, U.S.A., Chemist.
1910. Biggs, J. W. H., 318, High Street, Plumstead, S.E., Chemist.
O.M. Billing, H. S., 42, Kingsley Road, Mutley, Plymouth, Analytical and Managing Chemist.
1896. Billington, Chas., Heimath, Porthill, Longport, Staffordshire, Metallurgist.
1907. Bird, Charles S., jun., Messrs. F. W. Bird and Son, Library Dept., East Walpole, Mass., U.S.A., Paper Maker.
1896. Bird, Jno. B., 3, Brookside, Cambridge, Manure Manufacturer.
1895. Bird, Wm. R., (communications) 125, Goddard Avenue; (Journals) Laboratory, G.W.R. Works, Swindon, Wilts., Analytical Chemist.
1902. Bird, W. Robt., 217, Newport Road, Cardiff, Oil Merchant.
1885. Birley, R. K., c/o Chas. Macintosh and Co., Ltd., Cambridge Street, Manchester, Indiarubber Manufacturer.
1883. Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, E., Manufacturing Chemist.
1884. Bishop, Fred., c/o Burmah Oil Co., P.O. Box 67, Rangoon, Burmah, Technical Chemist.
1903. Bishop, Howard B., 1372, Union Street, Brooklyn, N.Y., U.S.A., Chemist.
1903. Bishop, J. T. F., Chemical Club, Victoria Hotel, Manchester, Secretary.
1905. Bixby, Willard G., 46th Street and 2nd Avenue, Brooklyn, N.Y., U.S.A., Blacking Manufacturer.
1905. Bjerregaard, A. P., 10724, Kimberley Avenue, Cleveland, Ohio, U.S.A., Varnish Chemist.
1912. Björnström-Steffanson, G., P.O. Box 51, Windsor Mills, Quebec, Canada, Consulting Engineer.
1909. Blacher, Prof. Carl, Polytechnicum, Riga, Russia, Chemical Engineer.
1904. Black, J. Wyclif, 67, Falcon Road, Edinburgh, Analytical Chemist.
1902. Black, W. Geoffrey, St. John's House, Christchurch Road, Norwich, Chemist.
1910. Blackie, Archibald, 223, James Street, Winnipeg, Canada, Chemist.
1894. Blackmore, H. S., P.O. Box 145, Mount Vernon, N.Y., U.S.A., Industrial Chemist.
1896. Blagden, Victor, 4, Lloyd's Avenue, London, E.C., Chemical Merchant.
1883. Blagden, W. G., Down Lodge, East Harting, near Petersfield, Hants, Chemical Merchant.
1897. Blair, Andrew A., 406, Locust Street, Philadelphia, Pa., U.S.A., Analytical Chemist.
1884. Blake, Jas., Thames Sugar Refinery, Silvertown, E., Manager.
1910. Blakeley, A. G., P. and R. Coal and Iron Co., Pottsville, Pa., U.S.A., Chemist.
1913. Blane, E. R., c/o I. Levinstein and Co., Inc., 115, 5th Street, Chelsea, Mass., U.S.A., Chemist.
1893. Blears, John, c/o Langworthy Bros. and Co., Ltd., Greengate Mills, Salford Dyer and Calico Printer.
1908. Blichfeldt, S. H., Vine Cottage, Southall, Middlesex, Bacteriologist and Fermentation Chemist.
1905. Bliss, H. J. W., United University Club, Pall Mall East, London, S.W., Chemist.
1889. Bloede, Victor G., Station D., Baltimore, Md., U.S.A., Manufacturing Chemist.
1908. Blomeley, Adam Y., c/o Arbuckle Bros. Sugar Refinery, Brooklyn, N.Y., U.S.A., Chemist.
1891. Bloomer, Fred J., Penpont, Clydach, R.S.O., Glamorgan, Nickel Works Manager.
1886. Blount, Bertram, Laboratory, 76 and 78, York Street, Westminster, S.W., Analytical Chemist.
1888. Bloxam, A. G., 29, Southampton Buildings, Chancery Lane, London, W.C., Chemist and Patent Agent.
1903. Blumenthal, Lionel, Ravensholme, Merry Bower Road, Broughton Park, Manchester, Chemist.
1886. Blundstone, E. R., 79, York Street, Westminster, S.W., Consulting Chemist.
1906. Blyth, M. Wynter, Lacton House, Tankersley, near Barnsley, Yorks, Analytical and Consulting Chemist.
1905. Blyth, Thomas R., Uphall Chemical Works, Ilford, Essex, Analytical Chemist.
1908. Blythe, Jas. R., Craiglea, Audenshaw, near Manchester, Leather Trades Chemist.
O.M. Boake, A., Warton Road, Stratford, E., Manufacturing Chemist.
1888. Boake, Edmund J., Widford Lodge, Chelmsford, Essex, Manufacturing Chemist.
1912. Boan, Robt., Laboratory, Government Railway Offices, Spencer Street, Melbourne, Vic., Australia, Engineer-in-charge.
1899. Boehm, Fred., 66, Crutched Friars, London, E.C., Chemical Agent and Merchant.
1910. Boehringer, Dr. R., 79, Milford Avenue, Newark, N.J., U.S.A., Chemist.
1898. Bogert, Prof. Marston T., Department of Organic Chemistry, Columbia University, New York City, U.S.A., Professor of Organic Chemistry.
1903. Boissevain, Chas. E. H., 92, Van Eeghenstraat, Amsterdam, Holland, Chemical Manufacturer.
1903. Bolam, Dr. H. W., Queen Margaret College, Glasgow, Lecturer on Chemistry.
1909. Bolden, Wm., Dalmellington Iron Works, Dunaskin, Ayrshire, Chemist.
1901. Bolton, E. Richards, 46, Stamford Brook Road, Hammersmith, W., Manufacturing Chemist.
1905. Bond, John, Crowlands, Southport, Engineer.
1905. Bond, Josiah, Alto, Arizona, U.S.A., Mining Engineer.
1912. Bone, S. C., 30, Long Lane, Garston, Liverpool, Chemical Works Manager.
1905. Bone, Prof. W. A., F.R.S., "Montrose," Harpenden Road, St. Albans, Herts, Professor of Chemical Technology.
1892 Bookman, Dr. S., 46, East 82nd Street, New York City, U.S.A., Chemist.
1888. Boor, Leonard G., 21, Mincing Lane, London, E.C., Chemical Merchant.
1912. Boorne, Wm. H., 54, Eldertou Road, Westcliff-on-Sea, Essex, Metallurgist.
1908. Booth, Jos. W., Atlantic Mills, Providence, R.I., U.S.A., Superintendent.
1904. Booth, N. Parr, Laboratory, Cadbury Bros., Ltd., Bournville, near Birmingham, Chemist.

1903. Boral, Robin, Rhodes Mount, Rhodes, near Manchester, Works Manager.
1897. Borland, C. R., Concord, Mass., U.S.A., Smokeless Powder Manufacturer.
O.M. Borland, W. D., Beacon Lodge, Bean, *via* Dartford Kent, Manufacturer of Explosives.
1903. Boroschek, Dr. L., 24, West 82nd Street, New York City, U.S.A., Chemist.
1908. Bose, R., 92–95, Upper Circular Road, Calcutta, India, Chemical Works Manager.
1890. Bost, W. D. Ashton, Cartvale Chemical Works, Paisley. Chemical Manufacturer.
1912. Boswell, Maitland C., Chemistry and Mining Building, University of Toronto, Canada, Lecturer on Organic Chemistry.
O.M. Bothamley, C. H., Weston-super-Mare, Somerset, County Director of Technical Instruction.
1890. Bott, Dr. W. Norman. *See* Norman-Bott, Dr. W.
1884. Böttinger, Dr. H. T. von, Elberfeld, Germany; and (subs.) c/o The Bayer Co., Ltd., 19, St. Dunstan's Hill, London, E.C., Colour Manufacturer.
1901. Bottomley, Dr. J. Frank, c/o The Thermal Syndicate, Ltd., Neptune Road, Wallsend-on-Tyne, Consulting Chemist.
1906. Bottomley, W., c/o The United Alkali Co., Ltd., Fleetwood Salt Works, Fleetwood, Engineer.
O.M. Boulton, H. E., 64, Cannon Street, London, E.C., Chemical Manufacturer.
O.M. Boulton, Sir Samuel B., Bart., 64, Cannon Street, London, E.C., Chemical Manufacturer.
1883. Boulton, T. S., 14, Freegrove Road, Caledonian Road, London, N., Manager.
1905. Bourne, Lyman M., c/o Goodyear Tire and Rubber Co., Akron, Ohio, U.S.A., Chemist.
1910. Bowater, J. W., Woodville, Beeches Road, West Bromwich, Works Manager.
1905. Bowen, Henry, South Street, East Aurora N.Y., U.S.A., Secretary.
1885. Bowen, S. B., "Caeffair," Llanelly, South Wales, Chemical Manufacturer.
1888. Bower, Frank. Brewery House, Spitalfields, E., Analytical Chemist.
1909. Bower, Joshua, c/o Kynoch, Ltd., Arklow, Co. Wicklow, Ireland, Chemist.
1897. Bower, Wm. H., 29th Street and Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemical Manufacturer.
1892. Bowes, Harry, Staveley, Broomfield Road, Heaton Moor, Stockport, Analytical Chemist.
1883. Bowley, Jos. John, Wellington Works, Battersea Bridge, London, S.W., Chemical Manufacturer.
1899. Bowley, J. Plunkett, 36, Argyll Mansions, Chelsea, London, S.W., Varnish Manufacturer.
1908. Bowman, Fred C., c/o General Chemical Co., Laurel Hill Works. Maspeth P.O., Long Island, N.Y., U.S.A., Chemist.
1884. Bowman, R., c/o Bowman's Ltd., Lythgoe's Lane, Warrington, Chemical Manufacturer.
1907. Bowman, Richard S., 23, Welldeck Road, West Hartlepool, Chemist.
1896. Bowman, Walker, 39, Cortlandt Street, New York City, U.S.A., Chemist.
1904. Boyce, Framroze H., 86, Hugh's Road, Chaupaty, Bombay, India, Technical Chemist.
1893. Boyce, Frank, c/o Goodall, Backhouse, and Co., White Horse Street, Leeds, Technical Chemist.
1910. Boyce, James, 225, West 18th Street, Chicago, Ill., U.S.A., Chemist.
1909. Boyd, Dr. Harold de H., c/o The Southern Cotton Oil Co., Ltd., Trafford Park, Manchester, Chemist.
1913. Boyd, Robert, c/o British Columbia Sugar Refining Co., Ltd., Vancouver, B.C., Canada, Chemist.
1909. Boyd, T. D., jr., Los Mochis, Sinaloa, Mexico, Sugar Refiner.
1899. Boyes, Herb. J., c/o Boyes & Kirk, Fabrica de Tecidos Belemzinho, Sao Paulo Brazil, Chemist.
1905. Brabrook, G. Hale, Manhattan, Nevada, U.S.A., Mining Engineer.
1910. Bracewell, Geoffrey A., 20, Heaton Grove, Bradford, Analytical Chemist.
1885. Bradburn, J. A., 311, Montgomery Street, Syracuse, N.Y., U.S.A., Manufacturing Chemist.
1902. Bradbury, S., Ferncliffe, Milton Grove, Glebelands Road, Ashton-on-Mersey, Chemist
1912. Bradford, Francis L. W., 92, Rotton Park Road, Edgbaston, Birmingham, Chemist and Works Manager.
1895. Bradford, Henry, Strettington, Goodwood, near Chichester, Analytical Chemist.
1896. Bragg, Everett B., 1838, Chicago Avenue, Evanston, Ill., U.S.A., Manufacturing Chemist.
1891. Braithwaite, Isaac, Ghyll Close, Kendal, Westmoreland, Drysalter.
1897. Braithwaite, Jno. O., Holme Lacey, Warren Road, Chingford, Essex, Pharmaceutical Research Chemist.
1903. Brame, J. S. S., 67, Coleraine Road, Blackheath, S.E., Demonstrator in Chemistry.
O.M. Brambam, W., Bank Chambers, 300, Mare Street, Hackney, N.E., Chemical Engineer.
1904. Brandeis, R., Oesterreichischer Verein f. Chem. und Metall. Produktion, Aussig, Austria, Chemical Manufacturer.
1902. Branegan, Jas. Aug., 712, North 20th Street, Philadelphia, Pa., U.S.A., Chemical Salesman.
O.M. Branson, F. W., Wynneholme, Far Headingley, Leeds, Pharmaceutical Chemist.
1903. Brassard, Fred A, 46, Vicar Lane, Bradford, Yorks, Aniline Dyestuff Importer.
1912. Brasse-Brossard, L., 451, Rideau Street, Ottawa, Canada, Agricultural Engineer.
1901. Brearley, Harry, c/o The Amalgams Co., Ltd., Attercliffe Road, Sheffield, Analytical Chemist.
1906. Breckenridge, John E., American Agricultural Chemical Co., Carteret, N.J., U.S.A., Chemist.
1908. Bregowsky, Ivan M., c/o Crane Co., 836, South Michigan Avenue, Chicago, Ill., U.S.A., Chemist.
1900. Brewis, E. T., 31, Belgrave Road, Leyton, E., Chemist.
1894. Breyer, Theodor, 725, Washington Avenue, Wilmette, Ill., U.S.A., Chemist.
1885. Briant, L., 24, Holborn Viaduct, London, E.C., Analytical Chemist.
1913. Bridge, Stanley W., c/o Dr. H. G. Colman, 1, Arundel Street, London, W.C., Analytical Chemist.
1890. Brierley, J. T., Highfield, Golden Hill, Leyland, near Preston, Lancs., Analytical Chemist.
1893. Briggs, J. F., Auchmuty Paper Mills, Markinch, Fifeshire, Technical Chemist.
1912. Briggs, O. W. H., Harborough Rubber Co., Day and Night Mills, Market Harborough, Rubber Works Chemist.
1885. Briggs, T. Lynton, 188, Central Avenue, Flushing, Long Island, N.Y., U.S.A., Technical Chemist.
1914. Brinsley, Frank, 74, Alexandra Road South, Manchester, Demonstrator in Chemistry.
1910. Brisbane, James W., c/o The Leather Cloth Co., Ltd., West Ham, E., Analytical Chemist.
1905. Bristol, Dr. H. Stanley, Elmhyrst, Newport, R.I., U.S.A., Chemist.
1886. Bristow, G. W., c/o Walter J. Crook, 10, Eastcheap, London, E.C., Chemical Manager.
1912. Britland, Wm. J., Pear Tree Cottage, Alvanley, near Helsby, Cheshire, Chemist.
1887. Broadbent, H., c/c Goodall, Backhouse, and Co., Sovereign Street, Leeds, Chemist.
1889. Brock, Arthur, Firework Factory, Sutton, Surrey, Firework Manufacturer.
O.M. Brock, J., The Cedars, Hoole, Chester, Chairman of United Alkali Co., Ltd.
1910. Brodribb, Noel K. S., Cordite Factory, Maribyrnong, Melbourne, Victoria, Australia, Chemist.
1912. Bromley, Henry S., Chelten and Wissahickon Avenues, Germantown, Philadelphia, Pa., U.S.A., Lace Manufacturer.
1909. Bronnert, Dr. E., Dornach, near Mülhouse, Alsace, Germany Artificial Silk Manufacturer.

1896. Brooke, C. B., jun., Colne House, Brantham, near Manningtree, Xylonite Manufacturer.
1900. Brooke, Jno. R., Government Opium Factory, Singapore, S.S., Superintendent.
1884. Brookes, E. A., c/o The Chilian Mills Co., Ltd., Chiguayante, Concepcion, Chile, Chemist.
1911. Brookfield, Henry M., 2, Rector Street, New York City, U.S.A., Glue Manufacturer.
1895. Brookman, Fred. W., Dewhirst, Syke, and (Jnls.) Sanitary Works, Rochdale, Manure Works Manager.
1906. Brooks, Cecil J., c/o M. M. Simau, Benkoelen, Sumatra, Ned. Indies, Metallurgist.
1909. Brooks, Theodore, Guantanamo, Cuba. Cane Sugar Manufacturer.
1907. Broome, James S., 18, Seedley Park Road, Pendleton, Manchester, Science Lecturer.
1911. Brothers, Horace E., York Drive, Latchford, Warrington. H.M. Inspector of Factories.
1909. Brothers, Wm., Meadow House, Tunstead Milton, near Whaley Bridge, Derbyshire, Chemical Manufacturer.
O.M. Brotherton, E. A., City Chambers, Leeds, Ammonia Distiller.
1884. Brown, Prof. A. Crum, F.R.S., 8, Belgrave Crescent, Edinburgh, Professor of Chemistry.
1905. Brown, Prof. Adrian J., West Heath House, Northfield, near Birmingham, Professor of Brewing.
1902. Brown, A. H. M., Hudson Bay Mine, Cobalt, Ont., Canada, Metallurgist.
1891. Brown, Cæsar R., 141, Victoria Avenue, Prittlewell, near Southend, Works Foreman.
O.M. Brown, D., 93, Abbey Hill, Edinburgh, Chemical Manufacturer.
O.M. Brown, D., Donaghmore, Tyrone, Ireland, Soap Manufacturer.
1890. Brown, Edw. Hilton, c/o W. Ropes and Co., St. Petersburg, Russia, Analytical Chemist.
1894. Brown, Geo. E., c/o "The British Journal of Photography," 24, Wellington Street, Strand, London, W.C., Chemist.
1910. Brown, Geo Winslow, Assabet Mills, Maynard, Mass., U.S.A., Chemist.
O.M. Brown, Henry, Benskin's Brewery, Watford, Herts., Brewing Chemist.
1899. Brown, Dr. Henry C., The Chemical Works, King's Lynn, Chemical Manufacturer.
O.M. Brown, Dr. Horace T., F.R.S., 52, Nevern Square, Kensington, S.W., Brewing Chemist.
1905. Brown, Hugh B., c/o Jas. Robertson and Sons, Ltd., Thrushgrove Works, Paisley, Chemist.
1906. Brown, Percy S., c/o B. O. Bowers Co., 136, Liberty Street, New York City, U.S.A., Chemist.
1892. Brown, Reginald B., c/o Badische Co., Ltd., 20—26, Brunswick Place, City Road, London, N., Technical Chemist.
1901. Brown, Samuel B., Ruthven, Bowden Lane, Marple, Cheshire, Calico Printer.
O.M. Brown, Walter, c/o Jas. H. Dennis and Co., Ltd., Widnes, Technical Chemist.
1900. Brown, Walter B., Victor Chemical Works, 509, Fisher Building, Chicago, Ill., U.S.A., Chemist and General Superintendent.
1901. Browne, Dr. Arthur L., 215, East Fayette Street, Baltimore, Md., U.S.A., Analytical Chemist.
1906. Browne-Cave, E. J. C. *See* Cave-Browne-Cave, E. J.
1905. Browning, Prof. K. C., Medical College, Colombo, Ceylon, Professor of Chemistry.
O.M. Browning, W., Broad Oak, Accrington, Calico Printer.
1902. Brownrigg, Marcus P., c/o Colonial Sugar Refining Co., O'Connell Street, Sydney, N.S.W., Chemist.
1902. Brownsdon, Dr. H. W., King's Norton Metal Co., Ltd., King's Norton, Birmingham, and (Jnls.) 109, Oxford Road, Moseley, near Birmingham, Works Chemist.
1902. Bruce, Alex., Laboratory, Hyde Park Corner, Colombo, Ceylon, Chemist.
1911. Bruce, Joseph, Jnls. to General Manager. Cape Explosives Works, P.O., Dynamite Factory, West Somerset, Cape Colony, Secretary.
1908. Bruce, Robert, c/o Clark, 191, Morningside Road, Edinburgh, Works Chemist.
1900. Bruce, Wm. T., 3, Lombard Court, London, E.C., and (Jnl.) c/o T. C. Allchin, Longfield, Kent, Director.
1892. Bruckmann, G. T., 109, 22nd Street, Guttenberg P.O., N.J., U.S.A., Chemical Engineer.
1911. Brunet, Louis, "Revue Générale des Sciences," 18, Rue Chauveau-Lagarde, Paris VIII, France, Chemist and Secretary.
O.M. Brunner, H., Holly Mount, Tarbock Road, Huyton, near Liverpool, Chemical Manufacturer.
1894. Brunner, H. Bertram, The Hollies, Hartford, Cheshire, Chemist and Electrician.
1887. Brunner, J. F. L., M.P., c/o Brunner, Mond, and Co., Ltd., Caxton House, Westminster, S.W., Chemical Manufacturer.
O.M. Brunner, Rt. Hon. Sir J. T., Bart., Silverlands, Chertsey; and (Journals) c/o Brunner, Mond, and Co., Ltd., Northwich, Cheshire, Chemical Manufacturer.
1910. Brunner, Dr. Philipp, 2, Via Ghega, Trieste, Austria, Merchant.
1902. Brunner, Roscoe, The Winnington Hall Club, Winnington, Northwich, Alkali Manufacturer.
1894. Brunton, J. Dixon, Wire Mill, Musselburgh, Scotland, Wire Manufacturer.
1904. Bryant, Arthur P., c/o Clinton Sugar Refining Co., Clinton, Iowa, U.S.A., Chemist.
1903. Bryant, V. Seymour, Trelawne, Crowthorne, Berks., Analytical Chemist.
1908. Bryce, Chas. C., 43-45, Great Tower Street, London, E.C., Merchant.
1894. Bryce, Thos., Tharsis Mines, Huelva, Spain, Chemist.
1897. Bryson, Jas., Pumpherston Oil Works, Midcalder, Scotland, Oil Works Manager.
1892. Buchanan, D. G., (Subs.) 40, St. Vincent Place, Glasgow; retain Journals; Analyst.
1908. Buchanan, Duncan G., 27, Woodlawn Avenue East, Toronto, Canada, Chemist (Rubber Works).
1904. Buchanan, E. F., 128, East Crescent Street, Marquette, Mich., U.S.A., Chemist.
1888. Buchanan, Jas., Caledonia Foundry, Brasenose Road, Liverpool, Engineer.
1904. Buchanan, John L., Braehead, Mill Road, Bromborough, Cheshire, Analytical Chemist.
1904. Buchanan, Joshua D., c/o Nobel's Explosives Co., Ltd., Polmont Station, Scotland, Chemist.
1910. Buchanan, Walter G., c/o Lautaro Nitrate Co., Taltal, Chile, Chemist.
1897. Buck, Chas. A., 521, Locust Street, South Bethlehem, Pa., U.S.A., Chief Chemist (Bethlehem Iron Co.).
1911. Budde, Dr. Carl, 1, Belford Road, Sunderland, Chemical Engineer.
1909. Buell, W. H., c/o Winchester Repeating Arms Co., New Haven, Conn., U.S.A., Chemist.
1909. Buggy, Thos., Butte, Montana, U.S.A., Assayer and Chemist.
1902. Bull, Irving C., 100, Maiden Lane, New York City, U.S.A., Chemist.
1899. Bult, Herbert J., 140, Fenchurch Street, London, E.C., Chemist.
O.M. Bumby, H., Bellevue, Sandbach, Cheshire, Iron and Chemical Works Director.
O.M. Bunker, H. E., 310, Kingston Road, Toronto, Ont., Canada, Technical Chemist.
1901. Bunting, Henry H., Oficina de Ensayes F. C. C. del P., Callao, Peru, Analyst.
1893. Burbridge, Jas., India-rubber Mills, Tottenham, N., India-rubber Manufacturer.
1910. Burbridge, Walter N., "Uplands," Foxley Lane, Upper Woodcote, Purley, Surrey, Analytical Chemist.
1896. Burford, Samuel F., The Ridgeway, Rothley, near Leicester, Analytical Chemist.
1889. Bürger, Dr. J., 1, Birch Avenue, Talbot Road, Old Trafford, Manchester, Technical Chemist.

1889. Burgess, Geo., Sydney Cottage, Halebank, Widnes, Chemist.
1913. Burgess, Herbert E., Holly House, Graham Road, Dalston, N.E., Manufacturing Chemist.
1889. Burgess, Wm. T., 20, Priory Road, Bedford Park, London, W., Analytical Chemist.
1902. Burkard, Dr. Ernst, Solothurn, Switzerland, Chemist.
1899. Burkhardt, Dr. G. A., Württembergischestrasse 32, Berlin, W. 15, Germany, Chemist.
1897. Burland, Lt.-Col. Jeffrey H., c/o Fraser Library, Montreal, Canada, Paper and Card Manufacturer.
1898. Burls, Herbert T., 2, Verulam Buildings, Gray's Inn, London, W.C., Mechanical Engineer.
1901. Burnand, Sydney, Manbré Saccharine Co., Ltd., Hammersmith, W., Manager.
1891. Burnet, Henry K., North Brook Vitriol Works, Bradford, Yorks, Sulphuric Acid Maker.
1897. Burnet, Jno. Jas., 18, University Avenue, Glasgow, and (Journals) 1, Montague Place, Bedford Square, London, W.C., Architect.
1909. Burnett, Arthur, 2417, Washington Boulevard, Chicago, Ill., U.S.A., Chemist.
1893. Burnham, J. C., Cordite Factory, Aruvankad, Nilgiri Hills, India, Analytical Chemist.
1900. Burr, Edmund C., 1722, Vallejo Street, San Francisco, Cal., U.S.A., Manufacturer.
O.M. Burrell, B. A., 8, Springfield Mount, Leeds, Analytical Chemist.
1910. Burrell, Keith, Burrell's Wharf, Millwall, London, E., Manufacturer.
1906. Burrough, Ernest J., Cale Distillery, Hutton Road, Lambeth, S.E., Rectifier.
1888. Burrows, Edw., Home Villa, Low Fell, Gateshead-on-Tyne, Alkali Works Manager.
1912. Burt-Gerrans, J. T., 46, Dewson Street, Toronto, Canada, Electro-Chemist.
1901. Burton, Alf., Canadian Dyers' Association, 2–16, Liberty Street, Toronto, Canada, Dyer and Finisher.
1903. Burton, Jno., 2, Green Street, Bethnal Green, E., Dye and Chemical Manufacturer.
1904. Burton, T. R., c/o Scott, Greenwood, and Son, 8, Broadway, Ludgate Hill, London, E.C., Technical Journalist.
1889. Burton, Wm., The Hollies, Clifton Junction, near Manchester, Potter's Chemist.
1906. Busby, Fred. E., Arnold Print Works, North Adams, Mass., U.S.A., Chemist.
1913. Bush, Dr. Harry T., 7, Gracechurch Street, London, E.C., Chemical Engineer.
1897. Bush, J. M., c/o W. J. Bush and Co., Ltd., Ash Grove, Hackney, E., Manufacturing Chemist.
1897. Butler, David B., 41, Old Queen Street, Westminster, S.W., Cement Expert.
1913. Butler, Geo. B., West Lyn, Hawthorne Terrace, South Bank, R.S.O., Yorks, Assistant Blast Furnace Manager.
1890. Butler, Paul, Lowell, Mass., U.S.A., Ammunition Manufacturer.
1885. Butler, Samuel, The Cedars, Compton, Wolverhampton, Brewer.
1905. Butler, Dr. T. H., c/o Wm. Butler and Co., Ltd., Crews Hole, Bristol, Chemist (Tar and Rosin Distillery).
1886. Butler, W. W., c/o Mitchells & Butlers, Ltd., The Brewery Library, Cape Hill, Birmingham, Brewer.
O.M. Butterfield, J. C., 79, Endlesham Road, Balham, S.W., Analytical Chemist.
1892. Butterfield, W. J. A., 66, Victoria Street, Westminster, S.W., Analytical Chemist.
1897. Butters, Charles, 54, New Broad Street, London, E.C., and (Journals) 121, 59th Street, Oakland, Cal., U.S.A., Metallurgist.
1900. Butterworth, Elwell R., c/o Reversible Collar Co., 111, Putnam Avenue, Cambridge, Mass., U.S.A., Chemist.
O.M. Byard, A. G., c/o Burt, Boulton, and Haywood, Apartado 8, Bilbao, Spain, Technical Chemist.
1905 Byrne, F. A., 2, Ludgate Hill, Birmingham, Director of Chemical Co.
1893. Byrom, T. H., Virol Research Laboratories, 10, Bedford Square, London, W.C., Analytical Chemist.
1887. Bythway, M., 44, Lloyd Street, Albert Square, Manchester, Drysalter.

C

1884. Cabot, Godfrey L., 940, Old South Building Boston, Mass., U.S.A., Manufacturing Chemist.
1907. Cabot, Samuel, 141, Milk Street, Boston, Mass., U.S.A., Chemical Manufacturer.
1906. Caddick, Arthur, Minas de Rio Tinto, Huelva, Spain, Works Chemist.
1889. Cadett, Jas., Ashtead, Surrey, Chemical Engineer.
1905. Cain, Dr. J. C., 24, Aylestone Avenue, Brondesbury Park, N.W., Colour Chemist.
1891. Caines, G. S. A., 7, Rochester Terrace, Camden Road, London, N.W., Analytical Chemist.
1897. Cairns, Wm., 5, Carlton Place, Glasgow, Plumber.
1907. Caistor, J. W. Y., Ty Coch, Deganwy, North Wales, Chemist.
1905. Calder, Prof. Edwin E., Long Meadow, R.I., U.S.A., Professor of Chemistry.
1897. Calder, W. A. S., 449, Hagley Road, Birmingham, Chemical Manufacturer.
1908. Caldwell, Dr. Robert J., Rosendale, Holland Park, Belfast, Ireland, Chemist and Works Manager.
1912. Caldwell, Wallace L., 1025½, North 24th Street, Birmingham, Ala., U.S.A., Engineering Chemist.
1888. Caldwell, Wm., Murray Street, Paisley, Scotland, Drysalter.
1912. Callan, Dr. Thomas, Chemical Laboratory, 49, High Street, Paisley, Technical Chemist.
1902. Calm, Dr. Chas. E., California Club, Los Angeles, Cal., and (Jnls.) P.O. Box 1517, New York City, U.S.A., Manufacturing Chemist.
1913. Calvert, A. F., Royston, Eton Avenue, London, N.W., Engineer.
1904. Calvert, Dr. Harry T., West Riding of Yorkshire Rivers Board, Wakefield, Chemist.
1895. Cambier, Jacob, 1401, Carteret Avenue, Pueblo, Colo., U.S.A., Chemist.
1904. Cameron, Walter S., 239, West 136th Street, New York City, U.S.A., Manufacturing Perfumer.
1908. Cameron, Wm., Balik Pappan, Koetei, East Borneo Sugar Refinery Manager.
O.M. Cammack, J., 34, Wolseley Road, St. Helens Lancashire, Technical Chemist.
1910. Campagne, Emile, Usine de Radet, Maule (Seine et Oise), France, Chemical Engineer.
1886. Campbell, Andrew, 51, Cluny Drive, Edinburgh, Chemist (Mineral Oil).
1912. Campbell, Arthur F., "Westwood," Middleton, Manchester, Research Chemist.
1908. Campbell, Fred. A., The Working Men's College, Latrobe Street, Melbourne, Victoria, Australia, Principal.
1910. Campbell, James R., 57, Dacre Hill, Rock Ferry, Cheshire, Chemist.
1907. Campbell, John A., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.
1912. Campbell, Kennedy, c/o British Dyewood Co., Ltd., Parkhead, Glasgow, Chemist.
1901. Campbell, Kenneth F., M.Inst.C.E., 1, Peel Street, Huddersfield, Civil Engineer.
1911. Campbell, L. E., Dept. of Agriculture, Peradeniya, Ceylon, Chemist.
1908. Campbell, Max E., Avila, Cal., U.S.A., Chemist.
1909. Campbell, Peter, Kearny, N.J., U.S.A., Linoleum Manufacturer.
1911. Campbell, Wm. E., c/o Gutta Percha and Rubber, Ltd., O'Hara Avenue, Toronto, Canada, Industrial Chemist.
1909. Candee, Chas. N., 39, South Drive, Toronto, Canada, Rubber Manufacturer.
1908. Canning, Ernest R., 137, Great Hampton Street, Birmingham, Manufacturer.

O.M. Cannon, M., 25, Stormont Road, Clapham Common, S.W., Vinegar Works Manager.

1913. Cantelo, Robt. C., Metallurgy Dept., School of Mining, Kingston, Ont., Canada, Chemist.

1891. Carden, Albert J., 20—21, Harp Lane, London, E.C., Distiller.

1893. Carey, Arthur, The Groves, Grassendale Park, near Liverpool, Chemist.

O.M. Carey, Eustace, The United Alkali Co., Ltd., 30, James Street, Liverpool; and (Journals) The Groves, Grassendale Park, near Liverpool, Chemical Manufacturer.

1906. Carey, W. Gordon, Fairholme, Raby Road, Stockton-on-Tees, Cheshire, Chemist.

1904. Cargill, J. T., c/o Finlay, Fleming, and Co., Rangoon, Burmah, East India Merchant.

1896. Carmichael, Herbert, Bureau of Mines, Victoria, British Columbia, Public Analyst and Assayer.

1884. Carmody, Prof. Patrick, River View, Rose Hill, Lostwithiel, Cornwall, Analytical Chemist.

1897. Carnell, Wm. C., 2136, North Camac Street, Philadelphia, Pa., U.S.A., Chemist.

1906. Caro, Dr. Nikodem, Meinekestrasse 20, Berlin W. 15, Germany, Analytical Chemist.

1893. Carpenter, Dr. C. C., South Metropolitan Gas Co., 709A, Old Kent Road, London, S.E., Civil Engineer.

1908. Carpenter, Edwin P., Culvert Works, Sheepcote Lane, Battersea, S.W., Manager of Casein, Ltd.

1900. Carpenter, Frank B., 11, South 12th Street, Richmond, Va., U.S.A., Chemist.

1900. Carpenter, Harry B., c/o Lister's Agricultural Chemical Works, Newark, N.J., U.S.A.

O.M. Carpenter, R. Forbes, 30, Buckingham Mansions, 359, West End Lane, West Hampstead, N.W., Ex-Chief Inspector under the Alkali, &c., Works Acts.

1904. Carr, Francis H., Kelvin, Church Avenue, Sidcup, and (Journals), Burroughs, Wellcome, and Co., Ltd., Dartford, Kent, Manufacturing Chemist.

1907. Carrier, C. F., jun., 1983, Railway Exchange Building, St. Louis, Mo., U.S.A., Manufacturing Chemist.

1904. Carter, A., Cuba Street, Petone, Wellington, New Zealand, Works Manager.

1905. Carter, Robert A., 4923. Osage Avenue, Philadelphia, Pa., U.S.A., Chemist.

1895. Carter, Stewart F., 43, Montana Street, North Adams, Mass., U.S.A., Technical Chemist.

1903. Carter, Thomas, West End View, Ravensthorpe, Dewsbury, Yorks, Works Chemist.

1886. Carter, W. Chas., c/o Dominion Iron and Steel Co., Sydney, C.B., Canada, Analytical Chemist.

1911. Carty, Ronald D., The Laboratories, Public Works Ministry Gardens, Cairo, Egypt, Analytical Chemist.

1889. Carulla, F. J. R., 84, Rose Hill Street, Derby, Chemical Manufacturer.

1906. Carveth, Dr. H. R., Niagara Electrochemical Co., Niagara Falls, N.Y., U.S.A., Works Manager.

1914. Casey, John A., Charlemont, Moy, Co. Tyrone, Ireland, Waterproof Manufacturer.

1903. Caspari, Dr. W. A., University College, Gower Street, London, W.C., Chemist and Physicist.

1899. Castro, J. Paul de, 1, Essex Court, Temple, London, E.C., Barrister-at-Law.

1895. Catlin, Chas. A., 133, Hope Street, Providence, R.I., U.S.A., Chemist (Rumford Chemical Works).

1909. Caulkin, Howard A., Mona Villa, Spencer Road, Belper, Analyst.

1906. Cave-Browne-Cave, E. J., Station Road, Brimington, Chesterfield, Works Chemist.

1896. Caven, Robt. M., University College, Nottingham, Lecturer in Chemistry.

1914 Caw, Wm., c/o J. Watson and Sons, Whitehall Soap Works, Leeds, Chemist.

O.M. Cawley, G., 82, Victoria Street, Westminster, S.W., Chemical Engineer.

O.M. Cawley, J., 278, Passaic Street, Newark, N.J., U.S.A., Analytical Chemist.

1897. Cawley, Thos. A., British Gelatin Works, Ltd., New Bedford Road, Luton, Gelatin Manufacturer.

1906. Chadsey, Stanley B., 476, Brunswick Avenue, Toronto, Canada, Chemist.

1891. Chadwick, Walter M., Thorneycroft, Westoe, South Shields, Chemical Works Manager.

1912. Chadwick, Walter W., 186, Wellington Street North, Hamilton, Ont., Canada, Chemist.

1910. Chakraborty, J., The Oriental Soap Factory, Goabagan, Calcutta, India, Technical Director.

1910. Challinor, Richard W., Chemical Laboratory, The Technical College, Sydney, N.S.W., Australia, Teacher of Chemistry.

1894. Chaloner, G. W., 26, Eagle Wharf Road, Hoxton, N., Chemical Manager.

1901. Chamberlain, G. E., 641, West Prairie Avenue, Decatur, Ill., U.S.A., Chemist.

1910. Chambliss, Prof. Hardee, Dept. of Chemistry, Oklahoma A. and M. College, Stillwater, Oklahoma, U.S.A., Professor of Chemistry.

O.M. Chance, A. M., Walcot, Torquay, Devonshire, Chemical Manufacturer.

1912. Chance, Clinton F., Messrs. Chance and Hunt, Ltd., Oldbury, near Birmingham, Managing Director.

1909. Chance, Edwin M., 61, South Penna Avenue, Wilkes-Barre, Pa., U.S.A., Chemist.

O.M. Chandler, Dr. C. F., Columbia University, West 116th Street, New York City, U.S.A., Professor of Chemistry.

1912. Chandler, Lee L., Research Laboratory, Pittsburgh Plate Glass Co., Creighton, Pa., U.S.A., Assistant.

1893. Chaplin, Dr. Edw. M., Public Analyst's Laboratory, Wakefield, Yorks, Analytical Chemist.

1890. Chapman, A. Chaston, 8, Duke Street, Aldgate, E.C., Analytical Chemist.

1906. Chapman Arthur J., Baronsmere, Stanhope Avenue, Church End, Finchley, N., and (Journals) c/o F. Claudet, Ltd., 6 and 7, Coleman Street, London, E.C., Analytical Chemist.

1906. Chapman, E. A., c/o Robert Heath and Sons, Ltd., Norton Works, Stoke on-Trent, Works Chemist.

O.M. Chapman, Spencer, 36, Mark Lane, E.C., Chemical Manufacturer.

1894. Charlier, A. C. J., 3, Bedford Road, South Tottenham, N., Consulting Chemist.

1912. Charlton, H. W., Patent Office, Dept. of Agriculture, Ottawa, Canada, Chemical Patent Examiner.

1900. Chase, March F., 1111, Marquette Building, Chicago, Ill., U.S.A., Chemist.

1889. Chase, R. L., Arnold Printworks, North Adams, Mass., U.S.A., Manager.

1898. Chattock, Herbert E., 23, Apsley Road, Clifton, Bristol, Oilcake Manufacturer.

1910. Chattopadhaya, P. C., 90, Maniktala Main Road Harrison Road P.O., Calcutta, India, Chemist.

1905. Cheeseman, Frank P., 100, William Street, New York City, U.S.A., Paint Manufacturer.

1901. Cheetham, Howard, 18, St. Ann Street, Manchester, Chartered Patent Agent.

1894. Cheney, John P., Messrs. Cheney Bros., South Manchester, Conn., U.S.A., Chemist and Silk Manufacturer.

1913. Chiaraviglia, Dr. Dino, Via Treviso 7, Rome, Italy, Director, Royal Explosives Laboratory.

1905. Chick, Oliver, 31, Auckland Road, Cranbrook Park, Ilford, Essex, Analytical Chemist.

1890. Chorley, Jno. C., Bewsey, Oxford Road, Birkdale, Lancs., Analytical Chemist.

O.M. Christie, J., Levenfield, Alexandria, Scotland, Dyer and Printer.

1903. Christie, John, c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Analytical Chemist.

1914. Christie, John T., c/o Messrs. John Miller and Co., Sandilands Chemical Works, Aberdeen, Analytical Chemist.

1908. Christie, Malcolm, Ardenlea, Portland Park, Hamilton, Scotland, Analytical Chemist.

1910. Christie, Dr. M. G., c/o The Otto-Hilgenstock Coke Oven Co., Post Office House, Leeds, Assistant General Manager.

1898. Christison, Geo., 2, Kelvinside Gardens, Glasgow, Engineer.

1907. Christopher, George, Walkden Works, Verney Road, South Bermondsey, S.E., Consulting Chemist.
1907. Christopher, J. E., Solvay Coke Works, Kirkless, Wigan, Assistant in Charge.
O.M. Chrystal, W. J., 7, West George Street, Glasgow, Chemical Manufacturer.
1908. Chrystall, E. R., c/o Curtis's and Harvey, Ltd., Cliffe at Hoo, Kent, Research Chemist.
O.M. Church, Sir Arthur, K.C.V.O., F.R.S., Shelsley, Kew, Surrey, Professor of Chemistry in the Royal Academy.
1890. Church, Elihu D., jun., 27, Cedar Street, New York City, U.S.A., Soda Manufacturer.
1906. Church, Sumner R., c/o Barrett Manufacturing Co., 17, Battery Place, New York City, U S A., Chemical Engineer.
1907. Churchill, Wm., Corning Glass Works, Corning, N.Y., U.S.A., Chemist.
1396. Claflin, Alan A., (Communications) 88, Broad Street, Boston ; and (Journals) Littleton, Mass., U.S.A., Manufacturing Chemist.
1909. Claflin, Albert W., 190, Waterman Street, Providence, R.I., U.S.A., Manufacturing Druggist.
1900. Clamer, Guilliam H., 46, Richmond Street, Philadelphia, Pa., U.S.A., Chemist.
1885. Clanahan, H. C., 79, Mosley Street, Manchester, Chemical Merchant.
1905. Clapp, Geo. A., 49, Federal Street, Boston, Mass., U.S.A., Chemist.
1891. Clapp, Ralph R., c/o B. P. Clapp Ammonia Co., Providence, R.I., U.S.A., Manager.
1889. Clapperton, J., jun., Analytical Chemist.
1913. Clark, A. Stanley, c/o Messrs. S. Pearson and Son, The Refinery, Minatitlan, Vera Cruz, Mexico, Technical Chemist.
1910. Clark, A. W., c/o Heath and Milligan Manufacturing Co., 1832, South Canal Street, Chicago, Ill., U.S.A., Superintendent.
1904. Clark, Arthur W., c/o Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemist and Bacteriologist.
1908. Clark, Chas. T., 1303, Sixth Street, Bay City, Mich., U.S.A., Manufacturing Chemist.
1913. Clark, Francis W., 35, Wilmington Square, London, W.C., Chemist.
1904. Clark, Prof. Friend E., Central University of Kentucky, Danville, Ky., U.S.A., Professor of Chemistry.
1910. Clark, Henry, 25, Adelaide Crescent, Brighton, Oil Refiner.
1909. Clark, Hubert A., 83, Amherst Street, Montreal, Canada, Canner.
1900. Clark, Jno., Broadway Works, Millwall Dock, London, E., Manufacturing Chemist.
1906. Clark, M. H., c/o Boston Rubber Shoe Co., Melrose, Mass., U.S.A., Chemist.
1902. Clark, Robt. M., 138, Bath Street, Glasgow, Chemist.
1906. Clark, Wm. B., 11, Fox Street Greenock, Chemist.
1907. Clark, Wm. H., 26, Barry Street, Dunston-on-Tyne, Analytical Chemist.
1912. Clark, William M., Niles Glass Works, Niles, Ohio, U.S.A., Chemist.
1904. Clarke, Alfred R., 613-617, Eastern Avenue, Toronto, Canada, Leather Manufacturer.
1908. Clarke, Arthur F., 13, Sloane Street, London, S.W., Analytical Chemist.
1897. Clarke, Wm. B., c/o Edison-Swan U.E.L. Co., Ltd., Ponders End, N., Electro-Chemist.
1889. Claus, Wm. H., c/o Claus and Co., Ltd., Clayton, Manchester, Manufacturing Chemist.
1909. Clayton, Ellis, Hazeldene, Deerpark Road, Belfast, Ireland, Lecturer on Bleaching, Dyeing, and Printing.
1895. Clayton, Dr. G. C., Croughton, near Chester.
1909. Clayton, H., "The Brae," Station Road, Crayford, Kent, Technical Chemist.
1894. Clayton, Robt. H., 1, Parkfield Road, Didsbury, Manchester, Chemist.
1910. Clayton, Will, Melville House, Accrington, Works Chemist.
1905. Clayton, W. E., Navy Victualling Yard, Kowloon, Hong Kong, Superintendent.
1907. Clement, Leonard H., Agnew Street, Lytham, Lancs., Chemist.
1893. Clemes, J. H., Cheriton, Newquay, Cornwall.
1884. Clerk, Dr. Dugald, F.R.S., 57-58, Lincoln's Inn Fields, London, W.C., Engineer.
1905. Clexton, Thos. J., 285, Congress Street, Boston, Mass, U.S.A., Manager (A. Klipstein and Co.).
1906. Clifford, Jos., Laboratory, Public Works Ministry Gardens, Cairo, Egypt, Chemist.
1913. Clifford, Sydney G.; 3, Norman Villas, East Dulwich, S.E., Analytical Chemist.
1900. Clifford, Wm., Sewage Outfall Works, Wolverhampton, Sewage Works Manager.
O.M. Cloud, T. C., 20, Bucklersbury, London, E.C., Metallurgist.
O.M. Clowes, Dr. F., The Grange, College Road, Dulwich, S.E.; retain Journals; Chemist.
1891. Clutton, J. H., Fonderie Mines de l'Aude, Villanière par Lastours (Aude), France, Assayer.
1911. Clymer, Wm. R., Publicity Department, National Carbon Co., Cleveland, Ohio, U.S.A., Manager.
1899 Coates, Chas. E., jun., Louisiana State University, Baton Rouge, La., U.S.A., Professor of Chemistry.
1911. Coates, Jos. E., The University, Edgbaston, Birmingham, Lecturer.
1888. Coats, Jno. T., 105, Broughton Street, Edinburgh, Manufacturing Chemist.
1893. Cobb, Prof. Jno. W., The University, Leeds, Prof. of Coal Gas and Fuel Industries.
1894. Coblentz, Dr. Virgil, 23, Vine Street, Brooklyn, N.Y., U.S.A., Research Chemist (R. R. Squibb and Co.).
1899. Cochran, Alfred, 559, Madison Street, Brooklyn, N.Y., U S.A., Chemist.
1911. Cochrane, Capt. J. B., Royal Military College, Kingston, Ontario, Canada, Professor of Physics and Chemistry.
1901. Cockburn, John A., Mayville, Stevenston, Ayrshire, Analytical Chemist.
1902. Cocking, Allan T., c/o Kynoch, Ltd., Lion Works, Witton, Birmingham, Ammunition Manufacturer.
1905. Coes, Chas. S., 1024, East River Street, Hyde Park, Mass., U.S.A., Oil Chemist.
1903. Coggeshall, Dr. G. W., 1807, Belmont Road, Washington, D.C., U.S.A., Chemical Engineer.
1887. Coghill, P. de G., Borax Works, Old Swan, Liverpool, Technical Chemist.
1884. Cogswell, W. B., Syracuse, N.Y., U.S.A., Chemical Engineer.
O.M. Cohen, Dr. J. B., 1, North Grange Mount, Headingley, Leeds, Professor of Organic Chemistry.
1897. Cohn, Alfred I., 122, East 74th Street, New York City, U.S.A., Chemist.
1901. Cohn, Sigmund, 13, Dutch Street, New York City, U.S.A., Metallurgical Chemist.
1904. Cohoe, Prof. W. P., 131, Walmer Road, Toronto, Canada, Professor of Chemistry.
1891. Colby, Albert L., 447, Lehigh Street, South Bethlehem, Pa., U.S.A., Metallurgical Engineer.
1899. Colby, E. A., Baker Platinum Works, Newark, N.J., U.S.A., Metallurgical Chemist.
O.M. Colby, W. H., Cairn Villa, St. Branock's Road, Ilfracombe.
1893. Coleman, W. H., 31, Queen's Terrace, Ayr, Scotland, Chemical Engineer.
1913. Colgate, R. T., 53, London Road, Reading, Works Chemist.
1905. Collett, John H., Sunnycroft, Tuffley, and (Jnls.) The Librarian, Free Library, Gloucester, Chemical Manufacturer.
1887. Collett, J. M., Wynstone Place, Brookthorpe, Gloucester, Chemical Manufacturer.
1901. Colley, Bernard T., c/o Braden Copper Co., Rancagua, Chile, South America, Superintendent.
1908. Collier, F. C., 457, Lansdowne Avenue, Westmount, Montreal, Canada, Analytical Chemist.
1903. Collier, Pierre, Companhia Industrial Pernambucana, Pernambuco, Brazil, Civil Engineer.

1893. Collin, Dr. C. A., Ferguslie Threadworks, Paisley. Textile Chemist.

1913. Collinge, H. G., c/o Naegeli and Co., Rua Theophilo Ottoni 21 (Caixa 562), Rio de Janeiro, Brazil, Technical Chemist.

1898. Collingridge, Frank, Highstone, New Road, Llanelly, South Wales, Chemist.

1899. Collins, S. Hoare, Armstrong College, Newcastle-on-Tyne, Agricultural Chemist.

1888. Collins, W. Hepworth. *See* Hepworth-Collins. W.

1913. Collinson, R. W., c/o Messrs. J. and J. Colman, Ltd., Starch Dept., Carrow Works, Norwich, Starch Manufacturer.

1899. Collis, Walter T., Parkhurst, St. Peter's Road, Harborne, Birmingham, Chemist.

1910. Collitt, Bernard, Chem. Laboratory, Messrs. Ruston, Proctor, and Co., Ltd., Lincoln, Chemist.

1910. Colman, Fred. J., c/o Brotherton and Co., Ltd., Wear Tar Works, Sunderland, Chemist.

1891. Colman, Dr. H. G., Woodthorpe, New Malden, Surrey, Analytical Chemist.

1892. Colquhoun, Ludovic, Dynamite Factory, Modderfontein, Transvaal, Analytical Chemist.

1894. Colquhoun, W., Tapton Close, Tapton House Road, Sheffield, Engineer.

1901. Colwell, J. Kear, Finsbury Town Hall, Rosebery Avenue, E.C., Analytical and Consulting Chemist.

1906. Comber, A. W., 23, Courtenay Gardens, Upminster, Essex, Metallurgical Chemist.

1900. Comey, Dr. Arthur M., Upland Avenue, opposite Summit Street, Chester, Pa., U.S.A., Technical Chemist.

1911. Comey, Robert H., Wenonah, N.J., U.S.A., Bleacher.

1906. Compton, Miss N. J., Library, University of Nebraska, Lincoln, Neb., U.S.A., Librarian.

1901. Connah, Jas., Laboratory, Custom House, London, E.C., Government Analyst.

1905. Conner, Arthur B., 217, West Boulevard, Detroit, Mich., U.S.A., Chief Chemist (Detroit Chemical Works).

1891. Conradson, Pontus H., Galena Oil Works, Franklin, Pa., U.S.A., Analytical Chemist.

1889. Conroy, Dr. Jas. T., 9, The Serpentine, Grassendale, Liverpool, Chemist.

1887. Constable, W. H., Australian Alum Works, Runcorn, Analytical Chemist.

1909. Cook, E. Bernard, 23, Cross Street, Finsbury, London, E.C., Manufacturing Chemist.

O.M. Cook, H. J., The Firs, Woodford Green, Essex, Soap Manufacturer.

1903. Cook, Jas. W., London and Provincial Dye Works, Hackney Wick, N.E., Dyer.

1898. Cook, Thos. Alex., East London Soap Works, Bow, E., Soapmaker.

1899. Cook, Walter G., 9, Hendon Lane, Finchley, N., Analytical Chemist.

1891. Cooke, Arthur W., "Abbey View," Walnut Road, Torquay, Analytical Chemist.

1907. Cooke, J. J. Verdin, 9, James Street, Liverpool, Salt Manufacturer.

1904. Cooke, W. Ternent, The University, Adelaide, South Australia, Lecturer in Chemistry.

1910. Coombs, Frank A., Technical College, Sydney, N.S.W., Australia, Lecturer on Tanning.

1913. Cooper, G. Stanley, 92, Harcourt Road, Sheffield, Chemist.

1910. Cooper, Leonard H., Royal Crown Soap Co., Calgary, Alberta, Canada, Chemist.

1901. Cooper, T. S., Beekfoot, Birch Hall Lane, Manchester, Calico Printing Chemist.

1891. Cooper, Walter J., The Elms, Lavernock, South Wales, Cement Works Manager.

1890. Corcoran, Bryan, 31, Mark Lane, London, E.C., Chemical Engineer.

1899. Cornelison, Dr. Robt. W., 275, West Summit Street, Somerville, N.J., U.S.A., Consulting Chemist.

1909. Cornell, Fred, 16, Place Royal, Montreal, Canada, Chemical Merchant.

1894. Coste, J. H., 2, Savoy Hill, Victoria Embankment, W.C., and (Journals) Utopia, Gloucester Road, Teddington, Chemist (Public Health Dept., L.C.C.).

1913. Cotterill, John W., 9, Broad Street Corner, Birmingham, Analyst.

1911. Cottrell, Henry E. P., c/o North Western Cyanamide Co., 313, Winchester House, Old Broad Street, London, E.C., Manager.

1912. Coupe, Geoffrey, 43, Hampton Road, Forest Gate, E., Chemist.

1914. Courian, Noubar, 14, Oaklands Avenue, Toronto, Canada, Rug Manufacturer.

1914. Cousins, F. G., 1, St. Cuthbert's Place, North Road, Durham, Science Master.

1894. Cousins, W. J., 55, Clerkenwell Close, London, E.C., Consulting Chemist and Director.

1912. Couture, Philibert, 21, Pond Street, Worcester, Mass., U.S.A., Assistant Chemist.

1909. Coventry, Bernard O., Lahore, Punjab, India, Deputy Commissioner of Forests.

1903. Cowan, A. Wallace, Bayfield, Bowdon, Cheshire, Analytical Chemist.

1906. Cowan, George D., Bridge House, Bridge Road, Millwall, E., Manager, Desilverising Works.

1912. Cowan, H. W., Bell Filtration Co., Ltd., 305, Kent Building, Toronto, Canada, Water and Sewage Specialist.

1893. Cowan, W. J., 12, Park Avenue, Wood Green, N., Fine Colour Manufacturer.

1910. Coward, Hubert F., 216, Plymouth Grove, Manchester, Lecturer in Chemistry.

1897. Cowburn, Arthur W., 20, Mount Street, Manchester, Chemical Merchant and Analytical Chemist.

1907. Cowburn, J. Robert, 10, Eastwood Road, South Woodford, Essex, Technical Chemist.

1891. Cowper-Coles, Sherard Osborn, 1 and 2, Old Pye Street, Westminster, S.W., and (Jnls.) The Cottage, French Street, Sunbury-on-Thames, Metallurgical Engineer.

1905. Cox, Harold N., c/o Lalance and Grosjean Mfg. Co. Woodhaven, N.Y., U.S.A., Chemist.

1884. Craig, Geo., Chemical Laboratory, 95, Bath Street Glasgow, Technical Chemist.

1895. Craig, Dr. Thos. J. I., c/o Peter Spence and Sons, Ltd., Alum Works, Manchester, Chemist.

1908. Craig, Wm. J., c/o Rio Tinto Co., Casa Colon, Huelva, Spain, Analytical Chemist.

1911. Crake, Ralph V., British South African Explosives Co., Dynamite Factory, Modderfontein, Transvaal, Chemist.

1901. Crane, Fred. D., 28, Hillside Avenue, Montclair, N.J., U.S.A., Consulting Chemist.

1902. Crane, Jasper E., c/o The Arlington Co., Arlington, N.J., U.S.A., Chemist.

1898. Cranfield, Wm., 11, Avondale Place, Halifax, Yorks, Teacher of Chemistry.

1903. Cranmer, Ridgeway, 170, 88th Street, Bay Ridge, Brooklyn, N.Y., U.S.A., Chemist.

1902. Craven, Alfred B., Northcote, Thorpe Road, Selby, Yorks, Analytical Chemist.

1906. Craven, J. A., 119, Moorside, Armley, Leeds, Chemist.

1891. Craven, Jno., The Ark, South Bersted, Bognor, Sussex, Chemist.

1906. Craven, John L., Niederwald, Hebers Ghyll, Ilkley, Yorks, Chemist and Salesman.

O.M. Crawford, D., Langdale's Chemical Manure Co., Ltd., St. Lawrence, Newcastle-on-Tyne, Manager.

1913. Crawford, John, c/o Lothian, 24, Briar Bank Terrace, Edinburgh, Works Chemist.

1908. Crawford, Lawrence, 17, Creswell Terrace, Dumfries, Scotland, Analytical Chemist.

1890. Crawshaw, E., 25, Tollington Park, London, N., Dye Merchant.

O.M. Cresswell, C. G., Ermyngarth, Ashtead, Surrey; and Broadway Chambers, Westminster, S.W., Chemist.

1901. Cribb, Cecil H., 136 Shaftesbury Avenue, London, W. Analytical and Consulting Chemist.

1909. Crichton, Charles, Kleinfontein Group C.A., Box 2, Benoni, Transvaal, Assayer.

1908. Crighton, Adam M., "London Place," Agecroft Print Works, Pendleton, Manchester, Calico Printer's Chemist.

1910. Crighton, David T., Nobel House, 195, West George Street, Glasgow, Buying Manager.

1905. Crighton, W. H., c/o Oro Concentration Co., Ltd., Globe Road, Kingsland Road, London. N.E., Chemist.

1890. Criper, Wm. R., c/o Messrs. D. Waldie and Co., Konnagar, near Calcutta, India, Manufacturing Chemist.

1911. Croasdell, Jas. F., 32, Handen Road, Lee, S.E., Engineer.

1901. Cronquist, G. W., Torekow, Sweden, Consulting Ceramic Engineer.

O.M. Crookes, Sir Wm., O.M., F.R.S., 7, Kensington Park Gardens, Notting Hill, W., Analytical Chemist.

1896. Crosby, Thos., Llanelly Steelworks, Llanelly, South Wales, Metallurgist.

O.M. Crosfield, A. L., 46, Bidston Road, Oxton, Birkenhead ; (Journals) c/o Prof. B. Moore, Biochemical Dept., The University, Liverpool, Analytical Chemist and Assayer.

1896. Crosfield, Capt. G. R., Lodge Lane, Warrington, Soap Manufacturer.

1908. Crosland, Percy F., Century Dye Works, Elland, Yorks, Technical Chemist.

1884. Cross, C. F., 4, New Court, Lincoln's Inn, London, W.C., Analytical Chemist.

1894. Crossley, Prof. Arthur W., F.R.S., Pharmaceutical Society, 17, Bloomsbury Square, London, W.C., Professor of Chemistry.

1904. Crossley, T. Linsey, 318, Lagauchetière Street West, Montreal, Canada, Technical Chemist.

1908. Croston, Henry, 583, Leonard Street, Brooklyn, N.Y., U.S.A., Foreman.

1894. Crow, Henry W., Hart's Lane, North Street, Barking, E., Tar Distiller.

1884. Crow, Dr. J. K., Ivydene, Westcombe Park Road, Blackheath, S.E., Technical Chemist.

1883. Crowther, Horace W., The Beeches, West Bromwich, Technical Chemist.

1906. Crowther, R. E., c/o Ferguson Bros., Ltd., Holme Head, Carlisle, Chemist.

1912. Cruikshanks, Dr. Geo. S., Royal Technical College, Glasgow, Chemist.

1884. Crumbie, W. D., 146, Washington Street, East Orange. N.J., U.S.A., Analytical Chemist.

1906. Cruser, Dr. Fred. Van D., c/o The Diamond Match Co., Barberton, Ohio, U.S.A., Chemical Engineer.

1892. Cullen, Wm., Dynamite Factory, Modderfontein, Transvaal, South Africa, Chemist.

1903. Cullen, W. H., The Castner-Kellner Alkali Co., Ltd., Wallsend-on-Tyne, Engineer.

1897. Culmann, Dr. J., c/o G. Siegle Co., Rosebank, Staten Is., N.Y., U.S.A., Chemist and Colourist.

1905. Culver, Ralph F., Ayer, Mass., U.S.A., Chemist.

1883. Cuming, James, jun., Chemical Works, Yarraville, Melbourne, Australia, Chemical and Fertiliser Manufacturer.

1912. Cuming, Wm. F., c/o Cuming, Smith, and Co. Proprietary, Ltd., Yarraville, Victoria, Australia, Manufacturing Chemist.

1907. Cunningham, James E., Minas Peña del Hierro, Provincia de Huelva, Spain, Analytical Chemist.

O.M. Curphey, W. S., 87, Canfield Gardens, South Hampstead, N.W., Chief Alkali Works Inspector.

1898. Curtis, Marvin, 108, Front Street, San Francisco, Cal., U.S.A., Wine Chemist.

1903. Cushing, Robt. P., 313, Saurens Street, Olean, N.Y., U.S.A., Chemist.

1902. Cutbush, Chas. G., 55, Byne Road, Sydenham, Kent, Electrical Engineer.

1899. Cutler, Fred. F., 166, Essex Street, Boston, Mass., U.S.A., Publisher.

1913. Cutts, H. Cyril, Brooklyn, Private Road, Sherwood, Nottingham, Embroidery Manufacturer.

1904. Cutts, Henry E., c/o Stillwell and Gladding, 181, Front Street, New York City, U.S.A., Technical Chemist.

D

O.M. Dacie, J. C., 30, Montserrat Road, Putney, S.W., Soap Manufacturer (retired).

1911. Dager, Herman J., 278, Jarvis Street, Toronto, Canada, Dominion Food Inspector.

1897. Dains, Herbert H., c/o J. E. Ferguson, 2, Union Court, London, E.C., Analytical Chemist

1908. Dale, H. Gordon, St. Ives, Fitzjohn Avenue, Barnet, Herts, Analytical Chemist.

1908. Dalton, Leonard V., 17, Gracechurch Street, London, E.C., Geologist (Petroleum).

1884. Daniell, Louis C., Royal Standard Brewery, Tamworth, New South Wales, Brewer.

1904. Danker, Dan. J., 73, Dean Road, Brookline, Mass., U.S.A., Dyestuff and Chemical Merchant.

1903. Dannenbaum, Dr. H., c/o National Ammonia Co., Frankford, Philadelphia, Pa., U.S.A., Secretary and Treasurer.

1885. Darby, Jno. H., Howard Chambers, 155, Norfolk Street, Sheffield, Ironmaster.

1911. David, Edward J., 249, Wood Avenue, Tottenville, Staten Is., N.Y , U.S.A., Chemist and Assayer.

1900. Davidson, Alex., 173, Colinton Road, Edinburgh, Analytical Chemist.

1899. Davidson, Charles, 65, Cadder Street, Pollokshields, Glasgow, Analytical Chemist.

1901. Davidson, G. M., Chicago and N.W. Railroad Shops, P.O. Station E., Chicago, Ill., U.S.A., Chemist.

1883. Davidson, J. E., 40, Percy Gardens, Tynemouth, Chemical Manufacturer.

1891. Davidson, Richard, 133, Victoria Road, Dundee, Oil Merchant's Clerk.

O.M. Davidson, R. Holden, c/o United Alkali Co., Ltd., Ammonia Soda Works, Fleetwood, Manager.

1904. Davidson, Robert, c/o Dalgety and Co., Ltd., 15, Bent Street, Sydney, N.S.W., Australia.

1911. Davidson, Thos. A., 57, Strathyre Avenue, Norbury, S.W., Chemist and Varnish Expert.

1905. Davidson, Dr. Wm. B., City Gas Works, Nechells, Birmingham, Chemist.

1906. Davies, Harry R., 80, Prince Street, Jamaica Plain, Mass., U.S.A., Chemist.

1898. Davies, Herbert E., The Laboratory, 28 Chapel Street, Liverpool, Analytical Chemist.

1907. Davies, James, 12, Harefield Road, Brockley, London, S.E., Scientific Apparatus Maker.

1912. Davies, Jas. Gordon, c/o Curtis's and Harvey, Ltd., Powder Mills, Tonbridge, Kent, Chemist.

1911. Davies, Jas. H., c/o Lever Bros., Ltd., Royal Liver Building, Liverpool, Chemist.

1896. Davies, Llewellyn J., 103, Bute Road, Cardiff, Analytical and Consulting Chemist.

1886. Davies, M. L., Standard Chemical, Iron, and Lumber Co., Toronto, Canada, General Manager.

1897. Davies, Saml. H., c/o Rowntree and Co., Ltd., The Cocoa Works, York, Research Chemist.

1908. Davies, T. H., c/o John Cox and Co.'s Successors, Stillhouse Lane, Bedminster, Bristol, Tanner.

O.M. Davis, A. R., 27, Wellington Road, Heaton Chapel, Stockport, Analytical Chemist.

1901. Davis, Bernard F., c/o Ore Trading Co., Casilla 112D, Santiago, Chile, Metallurgical Engineer.

1902. Davis, Charles B., c/o National Brewers' Academy, 402, West 23rd Street, New York City, U.S.A., Technical Chemist.

1902. Davis, Emerson, Detroit Chemical Works, Detroit, Mich., U.S.A., Chemist.

1912. Davis, E. Gordon, c/o Messrs. Curtis's and Harvey, Ltd., Cliffe at Hoo, Kent, Research Chemist.

1908. Davis, G. Keville, 265, Strand, London, W.C., Chemical Engineer.

O.M. Davis, H. W., 18, Crescent Road, Kingston-on-Thames, Analytical Chemist.

1907. Davis. Robt. W., jun.. 2505. South Garnet Street, Philadelphia, Pa., U.S.A., Chemist.

1906. Davis, V. P., 221, West Exchange Street, Providence, R.I., U.S.A., Chemist.

1897. Davis, Wm. A., 7, Carlton Bank, Harpenden, Herts, Chemist.

1911. Davis, Wm. C., The Hollies, St. Paul's Road, Smethwick, near Birmingham. Chemist.

1900. Daw, Fred W., Duffryn House, Ebbw Vale, Mon., Metallurgical Chemist.

1903. Dawes, Arthur W., 577, Providence Street, Albany, N.Y., U.S.A., Chemist.

O.M. Dawson, C. A., 32, Elm Hall Drive, Mossley Hill, Liverpool, Technical Chemist.

1886. Dawson, W. Haywood, British Alizarin Co., Ltd., Silvertown, E., and (Journals) 15, Wrottesley Road, Woolwich, S.E., Technical Chemist.

1901. Day, Dr. David T., U.S. Geological Survey, Washington, D.C., U.S.A., Geologist.

1913. Day, Frank E., c/o Condensed Milk Co. of Ireland, Lansdowne, Limerick, Ireland, Chemist.

1912. Day, G. A. C., Casilla No. 417, Lima, Peru (*viâ* New York). Oil Mill Manager.

O.M. Deacon, H. Wade, 8, Ullet Road, Liverpool; and (Jnls.) c/o C. E. Tyers, 186, Derby Road, Farnworth, Widnes, Alkali Manufacturer.

O.M. Deakin, H. T., Dewhurst, Egerton, near Bolton, Dyer.

1913. Deakin, J. Bartram, c/o Guest, Keen, and Nettlefolds, Ltd., By-Product Coke Ovens, Cwmbran, Mon., Coke Oven Manager.

1911. Dean, Arthur L., Sheffield Scientific School, New Haven, Conn., U.S.A., Assistant Prof. of Industrial Chemistry.

1903. Dean, Harry, Oak Villa, Greenhead Road, Huddersfield, Chemist.

1906. Dean, Harry, Armstrong College, Newcastle-on-Tyne, Demonstrator.

1892. Deaville, B., Beech Avenue, Nottingham Manufacturing Chemist.

1910. Deby, Bedford H., 27, Meadow Bank Avenue, Sharrow, Sheffield, Metallurgist and Chemist.

1899. De Castro, J. Paul. *See* Castro, J. Paul de.

1902. De Cew, J. A., 903, McGill Building, Montreal, Canada, Chemical Engineer.

1893. De Clerck, Maurice, Heule-lez-Courtrai, Belgium.

1884. Deering, W. H., I.S.O., Beauworth, Moretonhampstead, Devon, late Chemist to War Department.

1900. Deerr, Noel F., Analytical Chemist.

1902. Deghuée, Dr. Jos. A., 39, West 38th Street, New York City, U.S.A., Chemist.

1911. Dehn, Dr. Frank B., c/o F. Heron Rogers, Broad Sanctuary Chambers, Westminster, S.W., Chemist.

1901. De Jonge, Cornelius, 36, Doughty Street, Brooklyn, N.Y., U.S.A., Pharmaceutical Chemist.

1893. Delahaye, Philibert, 94, Rue St. Lazare, Paris (IX.), Gas Engineer.

1909. De Laire, Edgar, 47, Quai de Moulineaux. Issy, Seine, France, Industriel.

1901. Delany, Chas., c/o Elliott Bros., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Chemist.

1908. Dellschaft, Dr. F. H., Winnington, Northwich, Cheshire, Manufacturing Chemist.

1910. De Meeus, Etienne, Beacon Falls, Conn., U.S.A., Chemist.

1888. Dempsey, Geo. C., 165, Market Street, Lowell, Mass., U.S.A., Chemist.

1909. Demuth, Rudolph, 68, Salusbury Road. London, N.W., Manufacturer.

1899. Denham, Wm. S., The United College, St. Andrews, Scotland.

1913. Denington, R. C., 69, Dover Road. South Wanstead, Essex, Research Chemist.

1891. Denison, Joseph R., Messrs. J. R. Denison and Co., Valley Dyeworks, Bradford, Yorks, Analytical Chemist.

1911. Dennis, Louis, 26, Clapton Mount, Halifax Yorks, Works Chemist.

1908. Dennis. Martin, 859, Summer Avenue, Newark, N.J.. U.S.A., Manufacturing Chemist.

1907. Dennison, Henry S., c/o Dennison Manufacturing Co., Framingham, Mass., U.S.A., Manufacturer.

1898. Dent, Dr. Frankland, Government Analyst's Dept., Singapore, S.S., Government Analyst.

1912. Depierres, Gaston, The Indestructible Paint Co., King's House, King Street, Cheapside, London, E.C., Managing Director.

1905. Derby, Wallace G., c/o Nichols Copper Co., Laurel Hill, New York City, U.S.A., Assayer.

1913. Desch, Dr. Cecil H., Metallurgical Dept., The University, Glasgow, Lecturer.

1912. Dettmann, A. H., Stuart Street, Longueville, Sydney, N.S.W.. Leather Manufacturer.

1914. Detwiler, Jas. G., Box 210, Port Arthur, Texas, U.S.A., Chemist.

1906. Deverell. Louis C., 1, Shortlands Grove, Shortlands, Kent, Chief Chemist.

1908. Dew, Joseph A., 32, Forest Drive West, Leytonstone, N.E., Varnish Manufacturer.

1898. Dewar, Alex. H., c/o The Linoleum Manufacturing Co., Staines, Middlesex, Chemist.

O.M. Dewar, Sir J., F.R.S., 21, Albemarle Street, London, W., Professor of Chemistry and Physics.

1889. Dewey, Fred. P., Lanier Heights, Washington, D.C. U.S.A., Metallurgist.

1904. Dewhirst, J. A., Imperial Chambers, Halifax, Yorks, Analyst.

1909. Dewhirst, Wm. B., c/o Sager, 1128 Sixth Avenue, New Brighton, Pa., U.S.A., Technical and Engineering Chemist.

1903. Diamond, Wm., c/o John Bowes and Partners, Ltd., Marley Hill Colliery, Swalwell, R.S.O., Durham, Works Manager.

1913. Diaz-Ossa, Prof. Belisario, Casilla 962, Santiago, Chile, Prof. of Chemistry.

O.M. Dibdin, W. J., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.

1913. Dick, James, c/o Canadian Explosives, Ltd., Beloeil Station, P.Q., Canada, Superintendent.

1902. Dick, John, Wharf Road, Cubitt Town, London, E., Manager and Chemist.

1904. Dick, W. D., c/o Hugh Baird and Sons, 29, St. Vincent Place, Glasgow, Analytical Chemist.

1898. Dickenson, F. M., c/o Broken Hill Proprietary Co., 3, Great Winchester Street, London, E.C., Secretary.

1904. Dickenson-Gair, C. J. *See under* Gair.

1893. Dickerson, E. N., 141, Broadway, New York City, U.S.A., Lawyer.

O.M. Dickinson, A. J., 178, Lewisham High Road, Brockley, S.E., Tar Distiller.

1905. Dickinson, Cyril, Southwark Town Hall, Walworth Road, London, S.E., Analytical Chemist.

1898. Dickson, Samuel, 26, Tothill Street, Westminster S.W., Analytical Chemist.

1899. Dieckmann, Dr. Otto, 1180, Harrison Avenue, Cincinnati, Ohio, U.S.A., Chemist.

1914. Diehl, Dr. L. H., 703, Salisbury House, London Wall, London, E.C., Metallurgical Chemist.

1908. Diekman, Dr. George C., 115, West 68th Street, New York City, U.S.A., Professor of Pharmacy.

1894. Diestel, Wm., 117, Hudson Street, New York City U.S.A., Dyestuff Importer.

1908. Dill, Colby, Perth Amboy, N.J., U.S.A., Chemist.

1906. Dillon, Fred N., 16, Prospect Street, Fitchburg, Mass., U.S.A., Engineer.

1898. Dillon. Wm., The Lomas Gelatine Works, Southdown, Plymouth. Oil, Colour, and Varnish Manufacturer.

1911. Dissosway, Thurston N., 23, Vine Street, Brooklyn, N.Y., U.S.A., Chemist.

1903. Divine, Robt. E., 510, Bewick Avenue, Detroit, Mich., U.S.A., Chemist.

1899. Dixon, Fred. W., P.O. Box 43, Jamestown, N.Y. U.S.A., Dyer.

1888. Dixon, Prof. Harold B., F.R.S., Owens College, Manchester. Professor of Chemistry.

1902. Dixon, Wm. A., 97, Pitt Street, Sydney, N.S.W., Australia, Public Analyst and Assayer.

1909. Dixon, W. H., c/o Bryant and May, Ltd., Fairfield Works, Bow, London, E., Match Manufacturer.

1892. Dobb, Thos., c/o J. T. Dobb and Son, West Bar, Sheffield, Pharmaceutical Chemist.

O.M. Dobbie, J. J., F.R.S., Government Laboratory, Clement's Inn Passage, London, W.C., and (Jnls.) 4, Vicarage Gate, Kensington, W., Director.

O.M. Dobbin, Dr. L., Chemical Laboratory, University, Edinburgh, Professor of Chemistry.

1908. Dobbs, Ernest J., 16/17, Devonshire Square, Bishopsgate, London, E.C., Analytical Chemist.

1914. Dobson, Fred. W., Castle Grove, Nottingham, Lace Dyer and Dresser.

1913. Dobson, James, Holme Rook, Birch Lane, Longsight, Manchester, Technical Chemist.

1890. Dodd, A. J., Meadholme, Blackheath Park, S.E., Oil Manufacturer.

1907. Dodd, Arthur, Lyndhurst, Woolwich Road, Belvedere, Kent. Assistant Works Manager.

1889. Dodd, W. Ralph, Burton Grange, Goff's Oak, near Cheshunt, Chemical Works Manager.

1913. Dodds, Herbert H., c/o Kynoch, Ltd., Umbogintwini, Natal, Explosives Chemist.

1906. Dodds, Thos., c/o Reckitt and Sons, Ltd., and (Journals) 7, The Oval, Garden Village, Hull, Works Manager and Chemist.

1900. Dodge, Dr. Francis D., 291, Henry Street, Brooklyn, N.Y., U.S.A., Chemist.

1906. Dodsworth, Walter A., Journal of Commerce, 32, Broadway, New York City, U.S.A., Editor.

1897. Doerflinger, Wm. F., Rosebank, Staten Island, N.Y., U.S.A., Research Chemist.

1897. Dohme, Dr. Alf. R. L., Messrs. Sharp and Dohme, Baltimore, Md., U.S.A., Manufacturing Chemist.

1905. Dolan, H., Westbourne, Belvoir Road, Lower Walton, Warrington, Chemist.

1897. Dolge, Carl B., Westport, Conn., U.S.A., Manufacturer of Instruments and Antiseptics.

1914. Donald, James R., Sulphide, Ont., Canada, Chemical Engineer.

1903. Donald, Dr. Jas. T., 318, Lagauchetière Street West, Montreal, Canada, Consulting Chemist.

1912. Donald, R. M., c/o Lever Bros. Co., 174, Broadway, Cambridge, Mass., U.S.A., Soapworks Manager.

1900. Donald, Wm., Ridgefield Park, Bergen Co., N.J., U.S.A., Assayer and Chemist.

1913. Donaldson, Richard, 63, Waverley Gardens, Crossmyloof, Glasgow, Assistant Manager.

1902. Donaldson, Thos., c/o British South African Explosives Co., Ltd., Modderfontein, Transvaal, and Journal to 3, Raise Street, Saltcoats, Scotland, Chemist.

1905. Donnan, Prof. F. G., F.R.S., Chemical Laboratories, University College, Gower Street, London, W.C., Professor of Physical Chemistry.

1886. Doolittle, Orrin S., 388, Palisade Avenue, Yonkers, N.Y., U.S.A., Chemist.

1905. Doolittle, Roscoe E., 109, Hillside Avenue, Glen Ridge, N.J., U.S.A., Chemist.

1890. Dore, Jas., Copper Works, High Street, Bromley-by-Bow, E., Distiller's Engineer.

1911. Dorée, Dr. Charles, 58, Gore Road, South Hackney, London, N.E., Head of Chemistry Department, Borough Polytechnic.

1896. Doremus, Dr. Chas. A., 55, West 53rd Street, New York City, U.S.A., Professor of Chemistry.

O.M. Dott, D. B., Ravenslea, Musselburgh, Scotland, Analytical Chemist.

1911. Dougall, Jas. S. N., 305, Manufacturers Street, Montreal, Canada, Varnish Manufacturer.

1897. Douglas, Geo., Farfield Hall, Addingham, Yorks, Dyer.

1894. Douglas, Loudon M., Douglas Wharf, Putney, S.W., Chemical Manufacturer.

1909. Douglas, Robt. P., Prudential Buildings, Nelson Square, Bolton, Consulting Chemist.

1884. Douglas, William, Grafton House, Berkhamsted, Herts., Chemical Engineer.

1900. Doulton, H. Lewis, Royal Doulton Potteries, Lambeth, S.E., Potter.

1913. Doumin, Roland, 76, Tannsfeld Road, Sydenham, S.E., Analytical Chemist.

1900. Dow, Allan W., 126, Joralemon Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.

1898. Dow, Herbert H., Midland, Mich., U.S.A., Manufacturing Chemist.

1908. Dow, John W., 564, Park Avenue West, Mansfield, Ohio, U.S.A., Manufacturing Chemist.

1905. Dowbiggin, James, Craiglands, Albert Park, Lancaster, Chemist.

1913. Dowell, Henry L., 25, Greenbank Terrace, Taunton, Somerset, Chemist

1912. Doxey, Carl W., c/o Whalley Abbey Printing Co., Whalley, near Blackburn, Printworks Chemist.

1901. Doxrud, Christian, Technical School, Christiania, Norway, Professor of Chemical Technology.

1907. Doyle, B. W., 245, Lindell Avenue, Leominster, Mass., U.S.A., Manufacturer.

1902. Drake, Bryant S., 5830, Colby Street, Oakland, Cal., U.S.A., Chemist.

1911. Drake, Joseph W. D., Three Mills Distillery, Bromley-by-Bow, London, E., Distillery Brewer.

1912. Drake, Louis L., 138, North La Salle Street, Chicago, Ill., U.S.A., Editor and Publisher.

1886. Dreaper, W. P., 37–39, Broad Street Avenue, London, E.C.: and (Journals) 27, Willow Road, Hampstead Heath, N.W., Consulting Chemist.

1906. Drew, W. Newton, Raincliffe, Ecclesfield, near Sheffield, Chemical Manufacturer.

1896. Drewsen, Dr. Viggo B., 5, Beekman Street, New York City, U.S.A., Wood Pulp and Paper Expert.

O.M. Dreyfus, Dr. C., Claremont, Fallowfield, Manchester, Dye Manufacturer.

1904. Dreyfus, Dr. L. A., Maple Avenue, Rosebank, S.I., N.Y., U.S.A., Chemist.

1893. Dreyfus, S., Peel House, Peel Street, Denton, near Manchester, Chemist.

1899. Dreyfus, Dr. Wm., 57, East 96th Street, New York City, U.S.A., Chemist.

1898. Drummond, Dr. Isaac W., 436, West 22nd Street, New York City, U.S.A., Chemist.

1910. Drury, Chas. Dru, Hendon Gas Works, Sunderland, Engineer.

1899. Ducas, B. P., 25-27, South William Street, New York City, U.S.A., Chemical and Dyestuff Importer.

1907. Ducca, Dr. Wilhelm A., c/o U.S. Rubber Co., 58th Street at 11th Avenue, New York City, U.S.A., Chemist.

1905. Duché, E., 6, Eastcheap, London, E.C., and (Jnls.) Usines Duché, Vilvorde, Belgium, Merchant.

1909. Duchemin, René P., 6, Rue Chanoinesse, Paris IV., France, Chemical Engineer.

1897. Duckham, Alex., Phœnix Wharf, West Ferry Road, Millwall, E., and (Jnls.) Vanbrugh Castle, Blackheath, S.E., Chemical Manufacturer.

1908. Duckworth, G. F., Merritton, Ont., Canada, Works Manager.

1905. Duckworth, Harry S., Garner Printworks and Bleachery, Garnerville, Rockland Co., N.Y., U.S.A., Printworks Chemist.

1887. Dudley, Prof. W. L., Vanderbilt University, Nashville, Tenn., U.S.A., Professor of Chemistry.

1913. Duff, Alex. R., 211, Fern Avenue, Toronto, Canada, Rubber Chemist.

1899. Duff, Wm. S., Merric Lands, Westbury Road, Buckhurst Hill, Essex, Manufacturing Chemist.

1905. Duffus, W. B., 118, Braid Road, Edinburgh, Chemist.

1901. Dufty, Lawrence, 92, Tom Lane, Nether Green, Sheffield, Analytical Chemist.

1905. Duggan, Edw. J., c/o Warner Chemical Co., 141, Broadway, New York City, U.S.A., Vice-President.

O.M. Duggan, T. R., 52, East 41st Street, New York City, U.S.A., Analytical Chemist.

1898. Duisberg, Dr. Carl, The Bayer Co., Ltd. (Journals) Farbenfabrik, Leverkusen, bei Cöln a R., Germany: (subscriptions) 19, St. Dunstan's Hill, London, E.C., Chemist.

1888. Dukes, T. William, Box 10, Vryheid, South Africa, Merchant.

1906. Duncalfe, Roger, Forge Mills, Bestwood Colliery, Nottingham, Glue Manufacturer.

1889. Duncan, Arthur W., c/o J. Woolley, Sons and Co., Ltd., Victoria Bridge, Manchester, Analytical Chemist.

1909. Duncan, Jas., c/o Steel Bros. and Co., Ltd., 6, Fenchurch Avenue, London, E.C., Merchant.

1906. Dunford, Jno. H., Trent Side Bone Works, Nottingham, Assistant Manager.

1912. Dunkelsbuhler, F. S., 63, Brook Street, Grosvenor Square, London, W., Technical Chemist.

1905. Dunlop, Harry, 231, St. Vincent Street, Glasgow, Chemist.

1892. Dunn, Fred, 193, Collins Street, Melbourne, Victoria, Australia, Analytical Chemist.

O.M. Dunn, Dr. J. T., 10, Dean Street, Newcastle-on-Tyne, Consulting Chemist.

O.M. Dunn, P., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.

1908. Dünschmann, Dr. Max, c/o Meister, Lucius, und Brüning, Ltd., Ellesmere Port, Cheshire, Manager.

1901. Dunsford, Geo., Laboratory, Wigan Coal and Iron Co., Ltd., Wigan, Analytical Chemist.

1907. Dunstan, A. E., Technical College, East Ham, E., Head of Chemical Department.

1907. Dupré, F. H., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.

1907. Dupré, P. V., 2, Edinburgh Mansions, Howick Place, S.W., Analytical Chemist.

1905. Durfee, Winthrop C., 516, Atlantic Avenue, Boston, Mass., U.S.A., Manufacturing Chemist.

1897. Durkee, Frank W., Tuft's College, Medford, Mass., U.S.A., Professor of Chemistry.

1911. Durkin, Jos. A., c/o Butterworth Judson Co., Newark, N.J., U.S.A., Chemical Superintendent.

1907. Durrans, Thos. H., 10, Titchfield Terrace, Regent's Park, London, N.W., Chemist.

1899. Duryea, Chester B., 120, 85th Street, Brooklyn, N.Y.. U.S.A., Starch Manufacturer.

1906. Dushman, Saul, Research Laboratory, General Electric Co., Schenectady, N.Y., U.S.A , Electrochemist.

1891. Dvorkovitz, Dr P., 4. Broad Street Place, London, E.C., Technical Chemist.

1912. Dyche-Teague, F. C.. 258, Gloucester Terrace, Hyde Park, London, W., Analytical Chemist and Bacteriologist.

O.M. Dyer, Dr. B., 17, Great Tower Street, London. E.C., Analytical and Consulting Chemist.

1907. Dyes, Dr. W. A., 32, New Bridge Street, London, E.C.

1911. Dyke, F. Montague, Nelson Croft, Church Road, Bebington, Cheshire, Analytical Chemist.

O.M. Dyson, C. E., Flint, North Wales.

1902. Dyson, George W., 24, Clarkehouse Road, Sheffield, Analyst.

1892. Dyson, Septimus, Nyddcombe, Warlingham, Surrey, Manufacturing Chemist.

E

1905. Eager, Chas. E., 77, Pearl Street, Boston, Mass., U.S.A., Merchant.

1912. Eames, A. Spencer, 176, Tower Bridge Road, London, S.E., Registrar, Leathersellers' Technical College.

1904. Eames, Charles J., 99, Water Street, New York City, U.S.A., Consulting Chemist.

1910. Eardley, J. F.. 265, Glossop Road, Sheffield, Pharmaceutical Chemist.

1913. Earl, J. C., c/o Hon. Mrs. Lewis Benacre, Glen Osmond, South Australia.

O.M. Earp, W. R., Preston Brook, near Warrington, Chemical Manufacturer.

1910. Easterfield, Prof. Thomas H., Victoria College, Wellington, New Zealand, Prof. of Chemistry.

1884. Eastick, C. E., 13, King Edward Street, Whitechapel, E., Sugar Refinery Director.

1909. Eastick, J. C. N., 49A, Clapton Common, London, N.E., Electrochemist.

O.M. Eastick, J. J., 2. St. Dunstan's Hill, London, E.C., Consulting Sugar Expert.

1890. Eastlake. A. W., Grosmont, Palace Road, Streatham Hill, S.W., Consulting Petroleum Engineer.

1909. Eastlake, William H., c/o Imperial Wire and Cable Co., Montreal, Canada, Chemist.

1906. Eaton, B. J , Kuala Lumpur, Fed. Malay States, and (Journals) 171, Ribblesdale Road, Streatham Park, S.W., Government Chemist.

1909. Eberlin, Leon W., 11, First Street, Rochester, N.Y.. U.S.A., Chemist.

1892. Eddy, Harrison P., 14, Beacon Street, Boston, Mass., U.S.A., Superintendent.

1913. Edge, Alfred, Ravenhurst, Clayton Bridge, Manchester, Technical Chemist.

1885. Edge, Anthony, 79, West Milton Street, Readville, Mass., U.S.A., Chemist.

1909. Edge, J. Harold, " Great Marld," Smithills, Bolton, Lancashire, Technical Chemist.

1902. Edison, Thos. Alva, Edison Laboratory, Orange, N.J., U.S.A., Inventor and Manufacturer.

1908. Edmunds, Wm. T., 25. Church Road, Burry Port, South Wales, Assayer.

1911. Edwards, Alfred, The Laboratory, Meadow Lane Gas Works, Leeds, Analytical Chemist.

1909. Edwards, George M., 241, Pine Avenue West, Montreal, Canada, Paintworks Manager.

1902. Edwards, H. Leaton, The Shanty, Banks Avenue, Meols, Hoylake, Cheshire, Analyst.

1895. Ehrenfeld, Prof. Chas. H., York Collegiate Institute, York, Pa., U.S.A., Professor of Chemistry.

1896. Ehrhardt, Ernest F., Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany, Research Chemist.

1910. Eilsberger, Dr. Ernst, Deutsche Solvaywerke, Bernburg (Anhalt), Germany, Director.

1913. Eipper, William R., 1601, East 82nd Street, Cleveland, Ohio, U.S.A., Chemist.

1909. Eisenhart, M. H., c/o Eastman Kodak Co., Kodak Park, Rochester, N.Y., U.S.A., Chemist.

1901. Elkan, Leo A.. Dominick Street and Webster Avenue, Chicago, Ill., U.S.A., Tanner.

1901. Elkins, Arthur W., 116, Prospect Street, East Orange, N.J., U.S.A., Civil Engineer.

1884. Elliott, Dr. A. H., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Consulting Engineer and Chemist.

1912. Elliott, Edward, c/o Reckitts (Over-Sea), Ltd., Burke Street, Redfern, N.S.W., Australia, Chemical Engineer.

1907. Elliott, George K., c/o Lunkenheimer Co., Cincinnati, Ohio, U.S.A., Chief Chemist.

1896. Elliott, Dr. J. F., O'Connell Street, Sydney, N.S.W., Manufacturing Chemist.

1902. Elliott, Victor G., Chemical Works, Rozelle, Sydney, N.S.W., Australia, Manufacturing Chemist.

1905. Ellis, Carleton, 143, Gates Avenue, Montclair, N.J., U.S.A., Chemical Engineer.

1885. Ellis, C. J., Almorah Villa, Milngavie, near Glasgow, Technical Chemist.

1893. Ellis, E. Victor, 7, Hillside Crescent, Edinburgh, Analytical Chemist.

1894. Ellis, G. Beloe, 70, Chancery Lane, London, W.C., Patent Agent.

1913. Ellis, Henry D., 30, Blackheath Park, S.E., Metallurgical Engineer.

1912. Ellis, Percival W., " Ellesmere," Pyrford, near Woking, Tanning Material Merchant.

1910. Ellis, Ridsdale, 723, Monadnock Building, Chicago, Ill., U.S.A., Patent Agent.

1910. Ellis, Rowland H., c/o Olympia Oil and Cake Co., Barlby Road, Selby, Yorks, Analytical Chemist.

1891. Ellis, Prof. W. Hodgson, 74, St. Alban Street, Toronto, Canada, Professor of Applied Chemistry.

1891. Ellison, Henry, Northfield, Cleckheaton, Yorks, Manufacturing Chemist.
O.M. Elmore, A. S., 72, Gloucester Terrace, Hyde Park, London, W., Electro-Metallurgist.
1907. Elsden, A. Vincent, 10, Gourock Road, Eltham, Kent, Analytical Chemist.
1911. Elsdon, Geo. D., Analytical Department, 11, Broad Street, Birmingham, Analyst.
1904. Elson, J. Hugh, Monroe Drug Co., Quincy, Ill., U.S.A., General Manager.
1909. Ely, Benjamin, The Limes, Pye Bridge, near Alfreton, Tar Distiller.
1910. Emanuel, Louis V., 165, Rector Street, Perth Amboy, N.J., U.S.A., Metallurgical Engineer.
1910. Embley, Dr. E. H., 245, Latrobe Street, Melbourne, Victoria, Australia.
1902. Emery, Arthur L., c/o Smith, Emery, and Co., 651, Howard Street. San Francisco, Cal., U.S.A., Chemical Engineer.
1907. Emmons, Frank W., c/o Washburn Crosby Co., Minneapolis, Minn., U.S.A., Chemist.
1907. Emslie, B. Leslie, 1102-1105, Temple Building, Toronto, Canada, Agricultural Chemist.
1894. Enequist, John, 3710, Avenue J., Brooklyn, N.Y., U.S.A., Chemical Engineer.
1904. Englehard, Charles, 30, Church Street, New York City, U.S.A., Platinum Importer.
1895. English, Frank H., 89, Belgrave Road, Wanstead, N.E., Analytical Chemist.
1899. Enright, Bernard, 233, North 4th Street, Allentown, Pa., U.S.A., Analytical Chemist and Director.
1906. Ephraim, Dr. Julius, II, Königgraetzerstrasse 69, Berlin, S.W., Germany, Chemist and Patent Agent.
1911. Epps, James W., Holland Street, London, S.E., Chemist.
1909. Epstein, Harry M., 281, Edgecomb Avenue, New York City, U.S.A., Works Manager.
1914. Erbslöh, S. H., Hafen 29, Düsseldorf, Germany, Engineering Chemist.
1907. Erdoes, Julius, 1100, Brook Avenue, New York City, U.S.A., Chemical Engineer.
1902. Erhart, Wm. H., 81, Maiden Lane, New York City, U.S.A., Manufacturing Chemist.
1904. Ermen, Walter F. A., The Cranbery, Juiz de Fora, Minas Geraes, Brazil, Analytical Chemist.
1888. Erskine, J. K., P.O. Box 88, Benoni, Transvaal, Analytical Chemist.
1897. Escher, Paul, c/o Swift and Co., Chemical Laboratory, Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1884. Esilman, A., 38, Norwood Avenue, Southport, Lancashire, Analytical Chemist.
1913. Esling, Fred., 57, Grove Road, Strood, Kent, Chemical Engineer.
1912. Espenhahn, E. V., c/o Metropolitan Gas Co., 186, Flinders Street, Melbourne, Victoria, Australia, Works Chemist.
1910. Esslemont, Alfred S., Royal Exchange Buildings, Hood Street, Newcastle-on-Tyne, and (Jnls.) Orde House, Morpeth, Northumberland, Electrical Engineer.
O.M. Estcourt, C., 5, Seymour Grove, Old Trafford Manchester, Consulting Chemist.
1903. Euler, C. G., 18–20, Platt Street, New York City, U.S.A., Chemical Agent.
1912. Evans, Edward V., South Metropolitan Gas Co., Old Kent Road, London, S.E., Chief Chemist.
1883. Evans, Enoch, 660, Coventry Road, Birmingham, Accountant.
1903. Evans, F. Sparke, Avonside Tannery, Bristol, Tanner.
1905. Evans, Geo. A., 832, Yonge Street, Toronto, Canada, Pharmacist.
1913. Evans, George A., c/o Australian Explosives and Chemical Co., Ltd., 135, William Street, Melbourne, Victoria, Australia, General Manager.
1905. Evans, John, 67, Surrey Street, Sheffield, Analytical Chemist.
1908. Evans, Prof. Nevil Norton, Redpath Library, McGill University, Montreal, Canada, Associat Professor of Chemistry.
1889. Evans, R. E., Brewery Street, Stratford-on-Avon, Brewing Chemist.
1912. Evans, Sam, 4, Whickham Avenue, Dunston on Tyne, Chemist.
1912. Evans, Ulick R., 28, Victoria Street, Westminster, S.W., Consulting Electrochemist.
1898. Evans, Wm. Perceval, Canterbury College, Christchurch, New Zealand, Professor of Chemistry.
1909. Everette, Dr. W. E., 3512, South 11th Street, Tacoma, Wash., U.S.A., Consulting Chemical Engineer.
1912. Evers, Norman, c/o Allen and Hanbury's, Ltd., Bethnal Green, London, E., Analytical Chemist.
O.M. Evershed, F., c/o Clarke, Nickolls, and Coombs, Hackney Wick, N.E., Chemist.
1907. Eves, Archie P., c/o J. L. Gibney Tire and Rubber Co., Conshohocken, Pa., U.S.A., Chemist.
1894. Ewan, Dr. Thos., c/o Cassel Cyanide Co., Shuna Street, Maryhill, Glasgow, Chemist.
1905. Eynon, Lewis, 4, Stag Lane, Buckhurst Hill, Essex, Chief Chemist (London Beetroot Sugar Association).

F

1898. Fadé. Louis, c/o Dr. F. Stockhausen, Weissfrauenstrasse 7–9, Frankfort a/M., Germany, Chemist and Director.
1902. Faill, Jas., 52, Robertson Street, Glasgow, Technical Chemist.
1902. Fairchild, Benj. T., P.O. Box 1120, New York City, U.S.A., Manufacturing Chemist.
1911. Fairchild, B. Tappen, 74, Laight Street, New York City, U.S.A., Analytical Chemist.
1910. Fairclough, Brereton, Quarry House, Appleton, near Warrington, Cheshire, Miller.
1911. Fairfield, Thos. J., c/o W. T. Glover and Co., Trafford Park, Manchester, Analytical Chemist.
1903. Fairhall, E. J., 11, Bishop's Avenue, Upton Manor, E., Chemist.
O.M. Fairley, T., 17, East Parade, Leeds, Analytical Chemist.
1901. Fairlie, Jas., Camelon Chemical Works, Falkirk, Manufacturing Chemist.
1902. Fairweather, Wallace C., 62, St. Vincent Street, Glasgow, Engineer.
1898. Falding, F. J., 55, Broadway, New York City, U.S.A., Chemical Engineer.
1908. Fales, Harold A., 308, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Secretary (The W. N. Fales Co.).
1911. Farey, Frank O., 614, Canadian Express Building, Montreal, Canada, Chemist.
1910. Farr, Harry, Free Library, Cardiff, Librarian.
O.M. Farrant, N., c/o J. Nicholson and Sons, Chemical Works, Hunslet, Leeds, Chemist.
1913. Farrar, Stanley C., 104, Holly Road, Handsworth, Birmingham, Chemical Technologist.
1897. Farrell, Frank J., 15, Sandown Road, Great Yarmouth, Artificial Silk Manufacturer.
O.M. Farrington, T., 4, Waterloo Place, Cork, Ireland, Chemical Engineer.
1913. Farrow, F. D., Rhodes University College, Grahamstown, South Africa, Lecturer in Chemistry.
1909. Fath, Dr. Arthur, 149, Rue de Bruxelles, Ghent, Belgium, Chemical Engineer.
1903. Fawsitt, Dr. Chas. E., The University, Sydney, N.S.W., Australia, Prof. of Chemistry.
1914. Fearnley, C. A., 1, Alcester Terrace, Shepherd's Lane, Leeds, Technical Chemist.
1903. Feilmann, Dr. M. E., 92, Victoria Street, Westminster, S.W., Chemist.
1892. Feid, Walther, Linz a. Rhein, Germany, Chemical Works Director.

1913. Feldenheimer, Wm., 20, Holborn Viaduct, London, E.C., Clay Merchant.

1909. Fell, Wm. M. W., 27, Clarendon Road, Garston, Liverpool, Chemist.

1905. Felton, Herbert L., 516, East Second Street, South Boston, Mass., U.S.A., Distiller.

1900. Ferguson, Prof. Geo. A., 121, West 42nd Street, New York City, U.S.A., Professor of Analytical Chemistry.

O.M. Ferguson, Prof. J., The University, Glasgow, Professor of Chemistry.

1902. Fergusson, Donald M., c/o Acadia Sugar Refining Co., Halifax, N.S., Canada, Analytical Chemist.

1883. Fergusson, H., Prince Regent's Wharf, Victoria Docks, E., Technical Chemist.

1893. Fiebing, John H., 238, Reed Street, Milwaukee, Wis., U.S.A., Leather Trade Chemist.

1911. Field, Allan J., c/o G. Siegle Co., Rosebank, Staten Island, N.Y., U.S.A., Chemist.

1885. Field, E. W., Brewer.

1887. Field, S. S., 3, Glenluce Road, Blackheath, S.E., Manufacturing Chemist.

1891. Field, Wm. Eddington, Martin Street, Elsternwick, Melbourne, Victoria, Chemist.

1900. Fillis, Frank, 106, London Road, Neath, South Wales, Cement Works Manager.

1907. Finch, Archibald M., Vitriol and Chemical Works, Cattedown, Plymouth, Chemical Manufacturer.

1910. Findlater, James, c/o Price's Patent Candle Co., Ltd., Bromborough Pool, near Birkenhead, Chief Chemist.

1910. Findley, Albert E., Dept. of Applied Science, The University, Sheffield, Lecturer.

1899. Fingland, Jno. J., Kaslo, B.C., Canada, Analytical Chemist.

1911. Fink, F. W., 420, Riverside Drive, New York City, U.S.A., Manufacturing Chemist.

1904. Finn, Cornelius P., Hemsworth Colliery, near Wakefield, Yorks, Coke Ovens Manager.

1903. Fischer, Dr. Carl, 213–215, Water Street, New York City, U.S.A., Chemist.

1903. Fish, Chas. C. R., 439, Boylston Street, Boston, Mass., U.S.A., Chemist.

1911. Fish, Charles W., Rose Hill, Rawcliffe Bridge, S.O., Yorks, Chemist and Paper Technologist.

1900. Fisher, Henry, 16, East 96th Street, New York City, U.S.A., Teacher of Chemistry.

1895. Fison, Jno., Messrs. Jas. Fison and Sons, Thetford, Norfolk, Chemical Manufacturer.

1904. Fitch, A. J., 8, Waldgrave Gardens, Hall Lane, Upminster, Essex, Brewer's Chemist.

1900. Fitz-Randolph, R.B., State Laboratory of Hygiene, Trenton, N.J., U.S.A., Bacteriologist and Chemist.

1896. Flammer, E., c/o Kraemer und Flammer, Heilbronn a/N., Wurttemburg, Germany, Manufacturing Chemist.

1913. Fleming, M. D., 26, Aytoun Road, Pollokshields, Glasgow, Analyst.

1893. Fletcher, E. Morley, 30, Grosvenor Place, Newcastle-on-Tyne, Alkali Works Inspector.

O.M. Fletcher, F. W., c/o Fletcher, Fletcher, and Co., Ltd., Holloway, N., Manufacturing Chemist.

1907. Fletcher, H. T., c/o The Bauxite Refining Co., Hebburn-on-Tyne, Works Manager.

1891. Fletcher, R. Jaques, North Geelong, Victoria, Manufacturing Chemist.

1904. Fletcher, Wm. E., 411, West Broad Street, Tamaqua, Pa., U.S.A., Chemist.

1912. Flürscheim, Dr. Bernhard J., Rushmoor, Fleet Hampshire, Research Chemist.

1899. Focht, Louis, 12, Atterbury Avenue, Trenton, N.J., U.S.A., Civil Engineer.

1890. Foden, Alfred, 19, Lancaster Avenue, Sefton Park, Liverpool, Metallurgical Chemist.

1900. Foersterling, Dr. H., c/o Roessler Hasslacher Chem. Co., Perth Amboy, N.J., U.S.A., Chemist.

1895. Forbes, Paul R., 15, William Street, New York City, U.S.A., Chemist and Assayer.

1911. Ford, Edward J., 36, Rue Vandermaelen, Molenbeek St. Jean, Brussels, Chemist.

1893. Ford, J. B., jun., Michigan Alkali Co., Wyandotte Mich., U.S.A., Secretary and Treasurer.

1889. Ford, Jno. S., Abbey Brewery, Edinburgh, Analyst.

1885. Formoy, J. Arthur, Fairlight, Limpsfield, Surrey, Oil Expert.

1904. Forrest, Chas. N., Maurer, N.J., U.S.A., Chemist.

1898. Forrest, J. Kerr, Highdene, Albury Road, Guildford, Surrey, Manufacturing Chemist.

1890. Forrester, A. M., c/o Richmond Guano Co., Richmond, Va., U.S.A., Analytical Chemist.

1905. Forrester, H. A., Fabrica de Productos Quimicos, Acevedo 1710, Palermo, Buenos Ayres, S. America, Chemical Works Manager.

1909. Forshaw, Arthur, c/o John Wright and Co., Ltd., Essex Works, Aston, Birmingham, Works Chemist.

1902. Forstall, Alf. E., 84, William Street, New York City, U.S.A., Consulting Gas Engineer.

1902. Forster, Ferdinand E. P., c/o Messrs. Bass and Co., 19, Guild Street, and (Jnls.) The River House, Burton-on-Trent, Chemist.

1907. Forster, Francis, c/o Champion, Druce, and Co., Ltd., 6, Laurence Pountney Hill, London, E.C., Lead Manufacturer.

1899. Forster, Dr. M. O., F.R.S., 84, Cornwall Gardens, South Kensington, S.W., Chemist.

1884. Forster, Sir Ralph C., Bart., c/o Messrs. Bessler, Waechter, and Co., Salisbury House, Finsbury Circus, London, E.C., Chemical Merchant.

1884. Forth, Henry, Stoke Lacy, Marple, Cheshire, Drysalter.

1907. Forward, Charles C., Dept. of Inland Revenue Laby., 317, Queen Street, Ottawa, Canada, Chemist.

1906. Foster, Robt. K., Church Street, Middle Brighton, Melbourne, Victoria, Pharmaceutical Chemist.

O.M. Foster, R. Le Neve, Fulshaw Cottage, Wilmslow, Cheshire, Manufacturing Chemist.

1888. Foster, Wm., St. Martin's Terrace, Newton Park, Leeds, Manufacturing Chemist.

1906. Foucar, J. Louis, 15, Morden Road, Blackheath, S.E., Chemist.

1891. Fowler, Dr. Gilbert J., Rufford, Dickenson Road, Rusholme, Manchester, Consulting Chemist (Manchester Corporation Rivers Committee).

1898. Fowler, Theo. V., P.O. Drawer 15, Buffalo, N.Y., U.S.A., Chemical Works Manager.

1896. Fox, A. Stanley, Uplees, Faversham, Kent, Explosives Works Manager.

1912. Fox, Charles P., 395, Doyle Street, Akron, Ohio, U.S.A., Chemist.

1913. Fox, Edward Carey, 27, Scarth Road, Toronto, Canada, Pork Packer.

1898. Fox, Jno., Varuna, Grappenhall, Cheshire, Analyst.

1911. Fox, Dr. John J., 6, Alkham Road, Stamford Hill, N., Government Analyst.

1909. Fox, J. J., 19, Blackheath Rise, Lewisham, S.E., Managing Director, Tidman and Son, Ltd.

O.M. Fox, T., jun., c/o Fox Bros. and Co., Ltd., Wellington, Somerset, Wool Manufacturer.

1905. France, Edward W., Philadelphia Textile School Broad and Pine Streets, Philadelphia, Pa., U.S.A., Director.

O.M. Francis, E. G., 29, Matheson Road, West Kensington, W., Glucose Works Manager.

O.M. Francis, G. Bult, The British Drug Houses, Ltd., 22–30, Graham Street, City Road, London, N., Wholesale Druggist.

O.M. Francis, W. H., 11, Bramham Gardens, South Kensington, London, S.W., Wholesale Druggist.

1903. Francksen, Dr. Aug., 4803, Garden Street, Bridesburg, Philadelphia, Pa., U.S.A., Chemist.

1906. Frank, Prof. Dr. A., Bismarckstrasse 10, Charlottenburg, Germany, Chemist.

1908. Frank, Dr. Fritz, Lützowstrasse 96, Berlin, W., 68, Germany, Public Analyst.

1894. Frank, Jerome W., 29, Broadway, New York City, U.S.A., Chemist.

1886. Frankenburg, Isidor, Greengate Rubber Works, Salford, Manchester, Indiarubber Manufacturer.

1912. Frankenburg, Sydney, Hetlerston Grange, Weaverham, Cheshire, Indiarubber Manufacturer.
1895. Frankforter, Dr. G. B., University of Minnesota, Minneapolis, Minn., U.S.A., Prof. of Chemistry.
1904. Frankl, A., Clothilde Chemical Works, Nagy Bocskó, Hungary, Manager.
O.M. Frankland, H., Streonshalh, The Crescent, Linthorpe, Middlesbrough, Analytical Chemist.
O.M. Frankland, Prof. P. F., F.R.S., The University, Edgbaston, Birmingham, Professor of Chemistry.
1906. Fraps, Dr. Geo. S., Texas A. and M. College, College Station, Texas, U.S.A., Professor of Chemistry.
1901. Frasch, Hans A., 52, Broadway, New York City, U.S.A., Manager.
1900. Frasch, Herman, Whitehall Building, 17, Battery Place, New York City, U.S.A., Oil Refiner.
1910. Fraser, Arthur, Casilla 1464, Valparaiso, Chile, Analyat.
1891. Fraser, L. McG., Engineering Works, Dagenham, Essex, Chemical Engineer.
1902. Frederick, Geo. E., jun., P.O. Box 762, New York City, U.S.A., Chemical Merchant.
1885. Freear, H. M., Church Square, Ampthill, Beds. Analytical Chemist.
1900. French, Thos., 806, Stanley Street, Nelson, B.C., Canada, Chemist.
1911. French, Wm., Heron Chemical and Colour Works, Lancaster, Manager.
1903. Frerichs, Dr. F. W., 4320, Washington Boulevard. St. Louis, Mo., U.S.A., Manufacturing Chemist.
1913. Frew, John, Box 1, Johannesburg, South Africa, Chemist.
1907. Freytag, Henry, c/o O. Isler and Co., 35, Dickinson Street, Manchester, Chemical Merchant.
1886. Fries, Dr. Harold H., 92, Reade Street, New York City, U.S.A., Chemical Manufacturer.
1899. Fritzsche, Karl, c/o Schimmel und Co., Miltitz, near Leipzig, Germany, Manufacturer of Essential Oils.
1884. Frost, Joe, Rocky Mounnt, Somerset Road, Huddersfield, Manufacturing Chemist.
O.M. Fryer, Dr. A. C., 13, Eaton Crescent, Clifton, Bristol, Alkali Works Inspector.
1904. Fryer, P. J., 45, Burnaby Gardens, Chiswick, W., Analyst.
1889. Fuerst, Jos. F., 17, Philpot Lane, London E.C., Chemical and Oil Merchant.
1895. Fuerst, W. F., 87, Nassan Street, New York City, U.S.A., Chemical Merchant.
1913. Fulks, Elbridge B., 310, Columbia Building, Louisville, Ky., U.S.A., Manager, Tar Products Co.
1894. Fuller, Chas. J. P., 603, Chorley New Road, Horwich, near Bolton. Analytical Chemist.
1902. Fuller, Henry C., Institute of Industrial Research, Washington, D.C., U.S.A., Analytical Chemist.
1899. Fuller, Robt. F., Neston Park, Corsham, Wilts, Rubber Manufacturer.
O.M. Fuller, Wm., Vanbrugh Cottage, Maze Hill, S.E., Chemist.
1898. Fulmer, Elton, Pullman, Wash., U.S.A., Professor of Chemistry.
1909. Fulweiler, W. H., c/o United Gas Improvement Co., Broad and Arch Streets, Philadelphia, Pa., U.S.A., Engineer.
1885. Fyfe, Jno., 7, West George Street, Glasgow, Oil Works Director.

G

1909. Gaede, Chas. W., c/o National Silk Dyeing Co., Williamsport, Pa., U.S.A., Silk Dyer.
1913. Gage, Roscoe M., The Oaks, Springfield, Mass., U.S.A., Chemical Engineer.
1906. Gagnebin, Chas. L., 140, Oliver Street, Boston, Mass., U.S.A., Dyestuff Merchant.
1907. Gaines, Richard H., 147, Varick Street, New York City, U.S.A., Chemist (Board of Water Supply).
1904. Gair, C. J. Dickenson, 39, Cranston Road, Forest Hill, S.E., Analytical Chemist.
1912. Gajjar, M. J., Techno-chemical Laboratory, Girgaum, Bombay, India, Consulting Chemist.
1890. Gajjar, Prof. T. K., The Lines, Surat, India, Consulting Chemist.
1912. Gale, R. C., 38, Scarsdale Villas, Kensington, W., Technical Chemist.
1884. Gall, Henry 2,ᵃ Rue Blanche, Paris, France, Technical Chemist.
1905. Gall, J. B., c/o Callender's Cable and Construction Co., Belvedere, Kent, Chemist.
1911. Gallagher, Jas. L., c/o Lever Bros., Ltd., Sydney, N.S.W., Australia, Chemist.
1897. Galletly, J. C., c/o Newlands and Warner, 135, St. Vincent Street, Glasgow, Rubber Chemist.
1901. Gallivan, Dr. Frank B., 113, Third Street, South Boston, Mass., U.S.A., Chemist.
1903. Gallum, Albert F., 1000, North Water Street, Milwaukee, Wis., U.S.A., Tanner.
1901 Gallup, W. Arthur, Arnold Printworks, North Adams, Mass., U.S.A., Printer.
1901. Galpin, Harry T., 57, West 57th Street, New York City, U.S.A., Chemist.
1891. Galt, Hugh Allen, Columbia Chemical Co., Barberton, Ohio. U.S.A., Works Manager.
1887. Gamble, Jas. N., (Journals) A. E. Anderson, Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Soap Manufacturer and Oil Refiner.
1894. Gane, Eustace H., 91, Fulton Street, New York City, U.S.A., Pharmaceutical Chemist.
1901. Gansser, Dr. A., c/o Messrs. Lepetit, Dollfus, & Gansser, Garessio-Ponte (Provincia di Cuneo), Italy, Chemical Engineer.
1911. Garbutt, C. Durham, 2, Hartington Road, Garston, Liverpool, Analytical Chemist.
1911. Garcia-Robles, L., San Rafael Paper Co., Apartado 469, Mexico City, Mexico, Chemist.
1896. Gardair, Aimé, 51, Rue St. Ferréol, Marseilles, France, Director of Chemical Co.
1893. Gardiner, H. J., 242, 24th Street West, North Vancouver, B.C., Canada, Chemical Merchant.
1910. Gardner, Arthur L., 233, Water Street, Perth Amboy, N.J., U.S.A., Chemical Engineer.
1907. Gardner, Edward, The Tryst, Bigwood Road, Meadway, Hendon, N.W., Metallurgical Chemist.
1909. Gardner, Henry A., 19th and B. Streets N.W., Washington, D.C., U.S.A., Chemist.
1913. Gardner, Henry D., jun., Fairmead, The Goffs, Eastbourne, Technical Chemist.
1891. Gardner, Prof. Walter M., Technical College, Bradford, Director of Chemical and Dyeing Departments.
1897. Garfield, Jos., Thackley, Bradford, Yorks, Civil Engineer.
1888. Garibaldi, Joachim A., 21, Church Place, Gibraltar, Chemist.
1910. Garland, Charles S., 57, Garratt Lane, Wandsworth, S.W., Chemist and Works Manager.
1907. Garland, Herbert, P.O. Box 417, Cairo, Egypt, Chemist (Government Laboratory).
1911. Garner, John H., Sewage Works, Deighton, Huddersfield, Chemist.
1890. Garrett, Dr. F. C., Armstrong College, Newcastle-on-Tyne, Teacher of Science.
1900. Garrigues, W. E., 1304, Shelby Street, Louisville, Ky., U.S.A., Chemical Engineer.
1906. Garroway, Major John, 58, Buchanan Street, Glasgow, Chemist.
1908. Garson, Jas. W., 12, Avenue Road, Crouch End, N., Managing Director, Lewis Berger & Sons, Ltd.
O.M. Garton, Sir Richard, Messrs. Hill, Garton, and Co., Southampton Wharf, Battersea, S.W., Glucose Manufacturer.
1886. Gascoyne, Dr. W. J., 27, South Gay Street, Baltimore, Md., U.S.A., Analytical Chemist.
O.M. Gaskell, Holbrook, Erindale, Frodsham, Cheshire, Alkali Manufacturer.
1902. Gaskell, Holbrook, jun., Hillcroft, Church Road, Woolton, near Liverpool, Engineer.
1908. Gatehouse, Frank B., "Maristowe," Butts Green Road, Hornchurch, Essex, Chemist and Technical Journalist.

1912. Gates, Alfred E., c/o Messrs. T. Lye and Sons, Luton, Beds, Works Chemist.

O.M. Gatheral, Geo., 174, Soho Hill, Handsworth, Birmingham.

1906. Gaunt, Percy, Macclesfield Corporation Sewage Works, Prestbury, near Macclesfield, Chemist.

1912. Gee, Wm. J., 48, Kingsmead Road. Tulse Hill, London, S.W., Chemical Engineer.

1891. Geisler, Dr. Jos. F., New York Mercantile Exchange Building, 6, Harrison Street, New York City. U.S.A.. Consulting Chemist.

1912. Gellatly, Frank E., 644, Greenwich Street, New York City, U.S.A., Chemical Merchant.

1901. Gemmell, G. H., 4, Lindsay Place, George IV. Bridge, Edinburgh, Analytical Chemist.

1907. Gemmell, Wm., 13, Albany Gardens, Whitley Bay, Northumberland, Analytical Chemist.

1901. Gent, Percy W., Trentholme, Misterton, near Gainsboro', Chemist.

1897. Gent, Wm. T., Springfield, Misterton, near Gainsboro', Metallurgical Chemist.

1905. George, J. K., 347, Fifth Avenue, New York City, U.S.A., Manufacturer.

1912. Georgeson, George, Mutual Life Building, corner George and Wynyard Streets, Sydney, N.S.W., Manager of Oil Companies.

1913. Gepp, Herbert W., c/o Amalgamated Zinc (De Bavay's), Ltd., Broken Hill, N.S.W., Australia, General Manager.

1906. Gerkensmeyer. Henry H., 207, Mississippi Avenue, Joliet, Ill., U.S.A., Chemist.

O.M. Gerland, Dr. B. W., 105, Plantation Street, Accrington, Consulting Chemist.

1912. Ghislain, Raoul, 18, Rue du Mont de Piété, Mons, Belgium, Chemical Engineer.

1908. Gianoli, Prof. Giuseppe, Piazza Cordusio 2, Milano, Italy, Chemical Engineer and Editor (L'Industria).

1912. Gibb, W. Doig, South Metropolitan Gas Co., 709, Old Kent Road, London, S.E., Chief Engineer.

1911. Gibbings, W. Alan, P.O. Box Sannomiya 174, Kobe, Japan. Works Manager and Chemist.

1903. Gibbings, Wm., Woodside, Halebank, Widnes, Works Manager.

1910. Gibbins, Roland B., 18, Wheeley's Lane, Birmingham, Chemical Manufacturer.

1902. Gibbon, Edw., Belvedere, Park Road, Clydach, R.S.O., Glam., Works Chemist.

1904. Gibbs, A. E., c/o Pennsylvania Salt Manufacturing Co., Greenwich Point, Philadelphia, Pa., U.S.A., Manufacturing Chemist.

1913. Gibbs, Victor G., c/o Wm. Pearson, Ltd , Clough Road, Hull, Works Manager.

O.M. Gibbs, Wm. P., The Sulphite Pulp Mills, Hjerpen, Sweden, Analytical Chemist.

O.M. Gibson, J. M., c/o Buckley Brick and Tile Co., Buckley, *viâ* Chester, Brick and Tile Manufacturer.

1905. Gibson, John, 360–366, Collins Street, Melbourne, Vic., Australia, Concrete Manufacturer.

1913. Gibson, R. M., 58, Chester Road, Buckley, *viâ* Chester, Clay Goods Manufacturer.

1913. Gibson, Stanton, 28, Lordship Park, Stoke Newington, N., Factory Chemist.

1905. Gibson, Wm. F., 72, Woodstock Avenue, Golders Green, N.W., Works Chemist.

1899. Gifford, Wm. E., c/o Baker and Co., 408, New Jersey Railroad Avenue, Newark, N.J., U.S.A., Chemist.

1892. Gilbard, J. Francis H., 245, Dalston Lane, Hackney, N.E., Analytical Chemist.

1905. Gilbertson, Isaac H., 33, Broad Street, Rhodes, near Middleton, Lancs, Calico Printer.

1903. Gilby, Joseph W., 58, Beeches Road, West Bromwich, Staffs, Works Chemist.

O.M. Gilchrist, Percy Carlyle, F.R.S., A.R.S.M., M.Inst.C.E. & M.E., Reform Club, Pall Mall, London, S.W., Metallurgist.

1884. Gilchrist, Peter S., Charlotte, N.C., U.S.A., Chemical Engineer.

1900. Gildersleeve, W. H., Johnson City, Tenn., U.S.A., Chemist.

O.M. Giles, W. B., The Grange, Leyton, Essex, Chemical Manufacturer.

1886. Gill, Dr. Aug. H., Massachusetts Institute of Technology, Boston, Mass., U.S.A., Professor of Technical Analysis.

1913. Gill, Harold W., South African School of Mines and Technology, Johannesburg, South Africa, Lecturer on Chemistry.

1909. Gill, John H., 16, Premier Road, Gregory Boulevard, Nottingham, Soapworks Chemist.

1901. Gill, Wm. S., c/o Farquhar and Gill, North of Scotland Colour Works, Aberdeen, Colour and Varnish Manufacturer.

1901. Gilles, Wm. S., The Cottage, Bocking, near Braintree, Essex, Technical Chemist.

1910. Gillett, Horace W., c/o The Aluminium Castings Co., Detroit, Mich., U.S.A., Research Chemist.

1888. Gillman, Gustave, Ferrocarril de Murcia á Granada, Aguilas, Prov. de Murcia, Spain, Civil Engineer.

1891. Gimingham, Edw. A., Croyland, Clapton Common, N., Technical Electrician.

1886. Girdwood, Dr. G. P., 615, University Street, Montreal, Canada, Professor of Chemistry.

1906. Girtin, Thomas, H. L. Raphael's Refinery, 48, Thomas Street, Burdett Road, London, E., Bullion Refiner.

1903. Gladding, Thos. S., 181, Front Street, New York City, U.S.A., Analytical Chemist.

1886. Glaeser, F. A., Carpenters' Road, Stratford, E., Varnish Manufacturer.

1906. Glasel, Dr. Chas. J., Schönhauserstrasse 10, Berlin-Frz. Buchholz, Germany, Tanner.

1889. Glaser, Chas., 22, South Gay Street, Baltimore, Md., U.S.A., Consulting Chemist.

1906. Glass, A. Melville, 291, Camden Road, London, N.W., Patent Agent.

1901. Glegg, Robt., Agricultural Laboratory, Marischal College, Aberdeen, Analytical Chemist.

1894. Glen, Chas., Glengowan Printworks, Caldercruix, Scotland, Calico Printer.

1884. Glendinning, H., Winnington House, Northwich, Cheshire, Technical Chemist.

1888. Gloag, Robt. F., Lothian Road, Middlesbrough, Secretary.

1912. Gloag, Vivian F., Millbury House, Darlington Road, Ferryhill, Co. Durham, Chemical Works Manager.

1896. Glover, H., 6445, Emlen Street, Germantown, Philadelphia, Pa., U.S.A., Chemical Works Superintendent.

O.M. Glover, William, Albareda 27, Seville, Spain, Technical Chemist.

1911. Gmach, Ludwig T., Kew Bridge Label Works, Waldeck Road, Chiswick, W., Manufacturer.

1911. Goetschius, John M., c/o General Chemical Co., 25. Broad Street, New York City, U.S.A., Sales Manager.

1898. Golding, Jno., University College, Reading, Agricultural Chemist.

1906. Goldschmidt, Dr. Karl, Chemical Works, Essen-Ruhr, Germany, Manufacturing Chemist.

O.M. Goldschmidt, Dr. S. A., 11, Broadway, New York City, U.S.A., President (Columbia Chemical Works).

1897. Goldschmiedt, Dr. Guido, Wasagasse 9, Wien IX, Austria, Professor of Chemistry, University of Vienna.

1895. Goldsmith, Byron B., 19, East 74th Street, New York City, U.S.A., Vice-President (American Lead Pencil Co.).

1899. Goldsmith, Dr. Jno. N., 67, Chancery Lane, London, W.C., Chemist.

1906. Goodall, Wm. Leslie, Finboro' Road, Stowmarket, Suffolk, Works Chemist.

1909. Goodban, Leonard, 43, Addison Gardens, Kensington, London, W., Works Chemist.

1912. Gooderham, J. Leys, 49, Wellington Street East, Toronto, Canada, Chemist.

1906. Goodhue, Leonard H., c/o Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.

1904. Gooding, E. Claude, Willow House, Washford, Somerset, Chemist.

1913. Goodman, Alexander, c/o Lever Bros., Ltd., Sunlight Wharf, Upper Thames Street, London, E.C., Manager.
1898. Goodrich, Chas. C., 60, Broadway, New York City, U.S.A., Rubber Manufacturer.
1884. Goodwin, C. C., Racefield, St. Margaret's Road, Altrincham, Cheshire, Soapmaker.
1913. Goodwin, H. W., c/o Charles Case and Sons, Westbury, Wilts, Analytical Chemist.
1894. Goodwin, Dr. W. L., Library Dept., Gordon Hall, School of Mining, Kingston, Canada, Professor of Chemistry.
O.M. Goppelsroeder, Prof. Dr. F., Leimenstrasse 51, Basel, Switzerland, Professor of Chemistry.
1884. Gordon, J. G., Queen Anne's Mansions, Westminster, S.W., Steel Manufacturer.
1909. Gosse, Abel, 122, Boulevard St. Germain, Paris, France, Engineer (Poulenc Frères).
1904. Gotthelf, August H., Hastings-on-Hudson, N.Y., U.S.A., Chemist.
1890. Goulding, Sir Wm. J., Bart., North Wall, Dublin, Manure Manufacturer.
O.M. Gowland, Prof. W., F.R.S., 13, Russell Road, Kensington, W., Professor of Metallurgy (Royal School of Mines).
1886. Goyder, G. A., 110, Gawler Place, Adelaide, South Australia, Chemist and Assayer.
1890. Grabfield, Dr. J. P., c/o Morris and Co., Chemical Laboratory, Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1906. Graesser, Norman H., Argoed Hall, Llangollen, N. Wales, Manufacturing Chemist.
O.M. Graham, C. C., Oriel House, Scarborough, Yorks, Technical Chemist.
1908. Graham, C. W., 54, Dingwall Avenue, Toronto, Canada, Chemist.
1913. Graham, Jos. I., Chemical Laboratory, Bentley Colliery, near Doncaster, Yorks, Chemist.
1883. Grandage, H., c/o S. Smethurst and Sons, Woolfold Dye and Bleach Works, Bury, Lancashire, Dyer.
1914. Grandel, Paulin, Etablissements Kuhlmann, 13, Square de Jussieu, Lille (Nord), France, Managing Director.
1897. Granger, Dr. J. Darnell, 57. Holmwood Street, Newtown, Sydney, N.S.W., Australia, Analytical Chemist.
1905. Grant, Alexander, 15, Hermitage Drive, Edinburgh, Baker.
1896. Graves, Geo. H., 219. West 81st Street. New York City, U.S.A., Manufacturing Chemist.
1896. Graves, Walter G., 1950, East 90th Street, Cleveland, Ohio, U.S.A., Chemist.
1914. Gray, George, 3, Victoria Drive, Rock Ferry, Cheshire, Technical Chemist.
1884. Gray, G. Watson, 8, Inner Temple, Dale Street, Liverpool, Consulting Chemist and Assayer.
1911. Gray, Dr. G. W., c/o The Texas Co., Houston, Texas, U.S.A., Chairman Manufacturing Committee.
1910. Gray, H. Le Breton, c/o Eastman Kodak Co., Rochester, N.Y., U.S.A., Superintendent, Film Department.
1904. Gray, Jas., P.O. Box 5254, Johannesburg, Transvaal, Chemist.
1901. Gray, J. Campbell, The Cottage, Strines, near Stockport, Printworks Chemist.
1886. Gray, Jno., 3, Victoria Drive, Rock Ferry, near Birkenhead, Technical Chemist.
1896. Gray, Prof. Thos., Royal Technical College, Glasgow, Professor of Technical Chemistry.
1905. Gray, W. B., Messrs. Lever Bros., Durban, Natal, South Africa, Analytical Chemist.
1903. Gray, Wm. S., 76, William Street, New York City, U.S.A., Chemical Merchant.
1908. Gray, Wm. T., Port Credit, Ontario, Canada, Starch Manufacturer.
1909. Greeff, R. H., Thames House, Queen Street Place, London, E.C., and (Jnls.) "Arima," Denbridge Road, Bickley, Kent, Chemical Merchant.
1894. Greeff, R. W., Thames House, Queen Street Place, London, E.C., and (Jnls.) Elm Bank, Bromley, Kent, Chemical Merchant.
O.M. Green, Prof. Arthur G., 49, Cardigan Road, Headingley, and The University, Leeds, Professor of Tinctorial Chemistry.
1907. Green, Clarence, c/o Nicholson's Raincoat Co., Beaumont Works, St. Albans, Herts, Chemist.
1906. Green, Ernest, 98, Cheadle Road, Cheadle Hulme, Cheshire, Science Teacher.
O.M. Green, H., Hayle Mill, Maidstone, Paper Manufacturer.
O.M. Green, L., Lower Tovil, Maidstone, Paper Manufacturer.
1910. Green, Robert M., 24, Strand Arcade, Queen Street, Auckland, New Zealand, Chemist.
1908. Green, Dr. W. Heber, Chemical Laboratory, The University, Melbourne, Victoria, Lecturer in Chemistry.
O.M. Greenaway, A. J., The Orchard, Chertsey, Surrey, Sub-Editor of Chemical Society's Journal.
1909. Greenhough, George D., 21, Mincing Lane, London, E.C., Chemical Broker.
1913. Greenough, Thomas R., Beechwood, Leigh, Lancashire, Analytical Chemist.
O.M. Greenway, T. J., c/o Potter's Sulphide Ore Treatment, Ltd., 369, Collins Street, Melbourne, Australia, Metallurgist.
1902. Greenwood, Conrad V., Noyna, Dowhills Road, Blundellsands, Liverpool, Cotton Mill Manager.
1907. Greenwood, Herbert W., c/o The Boundary Chemical Co., Ltd., Cranmer Street, Liverpool, Metallurgical Chemist.
O.M. Greenwood, Holmes, Regent House, Hartmann Street, Accrington, Technical Chemist.
1897. Gref, Anthony, 117, Hudson Street, New York City, U.S.A., Patent Lawyer.
1909. Gregory, Cecil H., The Morgan Crucible Co., Ltd., Battersea, London, S.W., Crucible Manufacturer.
1907. Gregory, Joshua C., 128, Wellington Street, Glasgow, Analytical and Consulting Chemist.
1912. Gresham, Harold E., County Laboratories, 36, Dansie Street, Liverpool, Analytical Chemist.
1890. Griffin, Jno. R., Kemble Street, Kingsway, London, W.C., Chemical Apparatus Maker.
1886. Griffin, Martin L., c/o Oxford Paper Co., Rumford, Maine, U.S.A., Manager of Chemical and Electro-Chemical Department.
1912. Griffiths, Clement S., Central Queensland Meat Export Co., Ltd., Lake's Creek, Rockhampton, Queensland, Chemist.
1909. Griffiths, E., Dept. of Agriculture, 126, George Street North, Sydney, N.S.W., Australia, Chemist.
1902. Griffiths, Manfred E., Caizley House, Temple Road, Stowmarket, Suffolk, Explosives Chemist.
1912. Grimké-Drayton, Norman, Royal Mint Refinery, 19, Royal Mint Street, London, E., Metallurgist.
1902. Grimwade, Wilfrid R., 335—343, Spencer Street, West Melbourne, Vic., Australia, Manufacturing Chemist.
1900. Grimwood, Robt. G., 43, Leaside Avenue, Muswell Hill, N., Analytical Chemist.
O.M. Grindley, J., Upper North Street, Poplar, London, E., Tar Distiller.
1905. Grip, August E., 495, Columbia Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.
1888. Gripper, Harold, Great Central Railway, Gorton, Manchester, Analytical Chemist.
1909. Grist, John M., c/o Curtis's and Harvey, Ltd., Explosives Works, Cliffe-at-Hoo, Kent, Chemist.
1912. Groehing, Alb. von, 3. Lombard Street, London, E.C., Civil and Consulting Engineer.
1906. Groenewoud, Sidney H., 36, Grosvenor Road Highbury, N., Analytical Chemist.
O.M. Grossmann, Dr. J., 157, Plymouth Grove, Manchester, Consulting Chemist and Chemical Engineer.
1896. Grosvenor, Dr. W. M., Chemists' Building, 50, East 41st Street, New York City, U.S.A., Consulting Chemical Engineer.
1909. Grove, Daniel, "Yambo," Inverell, N.S.W., Australia, Diamond Buyer and Mine Owner.

O.M. Groves, C. E., F.R.S., 352, Kennington Road, London, S.E., Chemist (Thames Conservancy).

1907. Groves, J. Stuart, c/o E. I. du Pont de Nemours Powder Co., Georgetown, S.C., U.S.A., Chemist.

1899. Gudemann, Dr. E., 903, Postal Telegraph Building, Chicago, Ill.. U.S.A., Chemist.

1906. Guess, Prof. Geo. A., Mining Building, The University. Toronto, Canada, Professor of Metallurgy.

1911. Guild, Edward J., 5, Grove Terrace, Leek, Staffs, Analytical Chemist.

1899. Guild, Frank N., University of Arizona, Tucson, Arizona, U.S.A., Professor of Chemistry.

1909. Gulliek, Wm. A., Government Printing Office, Sydney, N.S.W., Government Printer.

1906. Gulline, Percy, c/o Columbia Textile Co., Lowell, Mass., U.S.A., Agent.

1913. Gundlach, H. R., 814, Hollins Street, Baltimore, Md., U.S.A., Chemist.

1904. Gundlach, Walter, 249, West 104th Street, New York City, U.S.A., Superintendent of Colour Works.

1905. Gundlich, Dr. Charles, c/o Thorium Chemical Co., Maywood, N.J., U.S.A., Technical Chemist.

1903. Gunn, Gilbert, 181, Bury New Road, Heywood, Lancs, Paper Mill Chemist.

1900. Günther, Chas. E., Liebig's Extract of Meat Co., Ltd., Thames House, Queen Street Place, London, E.C., Merchant.

1910. Günther, C. M., Condong Mill, Tweed River, N.S.W., Sugar Chemist.

1903. Guthrie, Alan, Dept. of Industries, Post Box 454, Madras, India, Leather Chemist.

1901. Guthrie, John M., 199, Ferry Road, Leith, Scotland, Analytical Chemist.

1909. Guttmann, Camillo J., 60, Mark Lane, London, E.C., Chemical Engineer.

1903. Guttmann, Dr. Leo F., School of Mining, Queen's University, Kingston, Ont., Canada, Professor of Physical Chemistry and Chemical Engineering.

1912. Guy, Wm. W., 6, Cecil Road, Upton Manor, E., Analytical Chemist.

1913. Gyton, Walter J., British Standard Cement Works, Rainham, Kent, Chemist.

H

1913. Haber, Prof. Dr. Fritz, Kaiser Wilhelm Institut, Faraday Weg 4, Post Lichterfelde 3, Berlin-Dahlem, Germany, Prof. of Physical and Electro-Chemistry.

1904. Hacking, D. H., Enfield Soap Works, Clayton-le-Moors, near Accrington, Soap Manufacturer.

1900. Haddoek, Arthur G. *See* Haydoek.

1887. Hadfield, Sir Robert A., Heela Works, Sheffield; 28, Hertford Street, Mayfair, London, W., and (Journals) c/o J. E. Mortimer, 220, Newhall Road, Attercliffe. Sheffield, Steel Founder.

1904. Hadley, Geo., Waterfall Lane, Blackheath, Staffs. Spelter Works Manager.

1906. Hagen, Dr. Carl, c/o E. I. du Pont de Nemours Powder Co., 20, Bishopsgate, London, E.C., Representative.

1887. Haig, Robert, Dollarfield, Dollar, Scotland, Chemical Engineer.

1904. Haigh, B. Wilson, By-Product Coke Oven Dept., Barnsley Main Colliery, Barnsley, Yorks, Chemical Engineer.

1896. Haigh, De Lagnel, 39, Hill Crest, Summit, N.J.. U.S.A., Chemist.

1888. Hailes, A. J. de, 15, Red Lion Square, London, W.C., Analytical Chemist.

1910. Hailstone, Harold J., 44, Cordley Street, West Bromwich, Works Chemist.

1889. Haines, Reuben, Haines Street, near Chew Street, Germantown, Philadelphia, Pa., U.S.A., Analytical Chemist.

O.M. Hake, C. Napier, Jnls. to c/o Dr. A. W. Hake, Medical School, Caxton Street, Westminster, S.W., Chemical Adviser.

1903. Halbert, Thos., c/o British South African Explosives Co., Modderfontein, Transvaal, Chemist.

1888. Hale, Edw. P., Endmoor, near Kendal, Analytical Chemist.

1887. Hall, Allan T., c/o Sissons Bros. and Co., Ltd., Hull, Oil Refiner and Varnish Manufacturer.

1905. Hall, Archibald A., Armstrong College, Newcastle-on-Tyne, Demonstrator in Chemistry.

1898. Hall. Clarence A., 18, McPherson Street, Mount Airy, Philadelphia, Pa., U.S.A.. Chemist.

1909. Hall, Harold, 98, Birkin Avenue, Hyson Green, Nottingham, Analyst.

1902. Hall, Henry, c/o Booth and Co., Irk Vale Works, Middleton, Lancashire, Dyer and Finisher.

1885. Hall, Lt.-Col. Jno. A., Longstone, Esquimault Old Road, Victoria, B.C., Canada, Analytical Chemist.

1912. Hall, Robert H., Weardale Tar Works, Spennymoor, Co. Durham, Chemical Works Manager.

1896. Hall, S. Godfrey, East London Soap Works, Bow, E., Soap Maker.

1886. Haller, Geo., Sussex House, 52, Leadenhall Street, London, E.C., Chemical Merchant.

1893. Haller, H. Loft, 26, Scale Lane, Hull, Analytical Chemist.

1912. Halliday, McDonald, c/o The Lagunas Synd., Ltd., Oficina North Lagunas, Iquique, Chile, Analytical Chemist.

1895. Halliwell, Edw., c/o Ribble Joint Committee, 2, Stanley Place, Preston, Chief Inspector.

1900. Halloek, Dr. Albert P., 3, James Street, Yonkers, N.Y., U.S.A., Chemist.

1892. Hamaguchi, Gihei, IV., Toyoharacho, Komatsubaratori, Wakayamashi, Japan, Soy Manufacturer.

1897. Hambly, Fred J., Buckingham, Quebec, Canada, Chemist.

1901. Hambuechen, Carl, 120, Wabash Avenue, Bellevue, Ill., U.S.A., Consulting Chemical Engineer.

1910. Hamburg, Dr. Max, c/o The British Diamalt Co., Sawbridgeworth, Herts, Chemist and Manager.

1911. Hamilton, David J., Locksley, Helensburgh, Dumbartonshire, Oil Refiner and Paint Manufacturer.

1904. Hamilton, Edward H., Virginia Smelting Works, West Norfolk. Va., U.S.A., Manager.

1912. Hamilton, James, 9, Esplanade Avenue, Whitley Bay, Northumberland, Analytical Chemist.

1884. Hamilton, Robert, Glengarnock Chemical Co., Ltd., Glengarnock, Ayrshire, Works Manager.

1892. Hamilton, Robt., 40, Sefton Terrace, Beeston Hill, Leeds, Analytical Chemist.

1898. Hammersley, W. Stanley, Rue Champhertrand, Sens (Yonne), France, Tanner.

O.M. Hammill, M. J., The Gables, St. Helens, Alkali Manufacturer.

O.M. Hammond, J., Gas Works, Eastbourne, Sussex, Gas Manager.

1905. Hancock, Thos. J., 4029, North Springfield Avenue, Chicago, Ill., U.S.A., Chemist.

1900. Haneoek, Walter C., 10, Upper Chadwell Street, Myddelton Square, London, E.C., Chemist.

1896. Hand, Daniel, 30, Mount Pleasant Avenue, Newark, N.J., U.S.A., Chemist.

1889. Handy, Jas. O., Pittsburgh Testing Laboratory, Seventh and Bedford Avenues, Pittsburgh, Pa., U.S.A., Chief Chemist.

1888. Hanks, Abbot A., 630, Sacramento Street. San Francisco, Cal., U.S.A., Assayer.

1901. Hanna, Charles E., P.O. Box 600, Montreal, Canada, Secretary.

1905. Hanson, H. Norman, The Oaks, Huddersfield Road, Brighouse, Yorks, Research Assistant.

1908. Hanson, W. G., c/o United States Glue Co., Milwaukee, Wis., U.S.A.

1909. Harbord. F. W., 16, Victoria Street, Westminster, S.W., Consulting Metallurgist.

1905. Harcourt, Prof. R., Ontario Agricultural College, Guelph, Ont., Canada, Professor of Chemistry.

1904. Hard, Dr. James M. B., 2A, del Canadá, Colonia de Sta. Julia, Mexico, D.F., Chemist and Pathologist.

1901. Hardcastle, G. Fred., 307, East Park Road, Leicester, Teacher of Science and Technology.

1894. Harden. Dr. Arthur. F.R.S., 5, Cambridge Gardens, Marlborough Road, Richmond, Surrey, Lecturer in Chemistry.

1910 Hardie, Thos., Newcastle and Gateshead Gas Co., Tyneside Road, Newcastle-on-Tyne, Gas Engineer.

1909. Harding, Herbert, 54, Streathbourne Road, Upper Tooting, S.W., Assistant Examiner (H.M. Patent Office).

1908. Hardman, Benj., c/o Kodak, Ltd., Wealdstone, Middlesex, Analytical Chemist.

1912. Hardwick. Walter A. N., 26, West Kensington Mansions, London. W., Chemist.

1900. Hardwick, W. Roscoe, 13, Batavia Buildings, Hackins Hey, Liverpool, Chemist.

1905. Hardy, Chas. H., c/o Reckitt and Sons, Ltd., Hull. Chemist.

1907. Harfeld, Louis E., c/o Messrs. Ohlenschlager Bros., Shanghai House, Botolph Lane, London, E.C., Merchant.

1913. Harger. Dr. John, Grange Hollies, Gateacre, Liverpool.

1906. Hargreaves, Frank, Hough Green, Widnes, Chemist.

1896. Hargreaves, James, May Villa, Peel House Lane, Widnes, Chemical Engineer.

O.M. Hargreaves, Jno., Widnes, Alkali Manufacturer.

1904. Harker, Dr. George, Mount Errington, Hornsby, Sydney. N.S.W., Australia, Chemist.

1909. Harland, Robert M., 37, Lombard Street, London, E.C., Analytical Chemist and Assayer

1893. Harlock, E. B., Newton House, Middlewich, Chemical Manufacturer.

1898. Harman, Edw. A., Gas Works, Huddersfield, Gas Engineer, M.Inst.C.E.

1905. Harper, Dr. Henry W., University of Texas, 2216, Rio Grande Street, Austin, Texas, U.S.A., Professor of Chemistry.

1912. Harper, J. G., Kynochtown, Stanford le Hope, Essex, Managing Chemist.

1913. Harper, William, P.O. Box Sannomiya 174, Kobe, Japan, Works Chemist.

1912. Harran, Dr. Edward B., Abbey Field, Sandbach, Cheshire, Chemist.

1893. Harris, Arthur, 22, Marsh Gate Lane, Stratford, E., Soap Maker.

1885. Harris, Booth, jun., Beeleigh, Victoria Road, Buckhurst Hill, Essex, Soap Maker.

1897. Harris, Fred. W., 38, Cochrane Street, Glasgow, Public Analyst.

1907. Harris, John B., Danforth Avenue, Toronto, Canada, Manufacturer of Glues and Fertilisers.

1906. Harris, Jonathan W., c/o Western Electric Co., 463, West Street, New York City, U.S.A., Chemist.

1907. Harris, Thos. E., c/o The Union Acid Co., 17, Cooper Street, Manchester, Chemical Merchant.

1906. Harris, Wm. G., jun., 35, Fraser Avenue, Toronto, Canada, Metallurgist.

1905. Harrison, E. F., Langholm, Edgar Road, South Croydon, Analytical Chemist.

1909. Harrison, Edwin D., 86, Harrison Place, Irvington, N.J., U.S.A., Celluloid Manufacturer.

1883. Harrison, G. Herbert, Hagley, Stourbridge, Firebrick Maker.

1892. Harrison, Prof. John B., C.M.G., Government Laboratory, Georgetown, British Guiana, Chemist.

1907. Harrison, W., 3, Regent Terrace, Hyde Park, Leeds, and (Jnls.) Fuel Dept., The University, Leeds, Technical Investigator.

1896. Hart, Bertram, c/o Tennants and Co., Clayton, Manchester, Analyst.

1886. Hart, Bertram H., Rosslyn, High Street, Sidcup, Kent, Analytical Chemist.

O.M. Hart, Dr. E., Gayley Hall, Lafayette College, Easton, Pa., U.S.A., Professor of Chemistry.

1890. Hart, H. W., Winthrop, Ansdell Road, Lytham, Lancashire, Analytical Chemist.

1897. Hart, Wm. Beamont, Manchester Laboratory, 8, Exchange Street, Manchester, Consulting Chemist.

1908. Hartley, Bernard C., 56, Wood View, Manningham, Bradford, Analytical Chemist.

1912. Hartley, Harold, c/o The Richmond Gas Stove and Meter Co., Ltd., Warrington, Research Chemist.

1883. Hartley, Joseph, 73, East Road, Stockport Road, Longsight, Manchester, Technical Chemist.

1912. Hartley, Thos., 64 Westlecot Road, Swindon Wilts, Teacher of Technical Chemistry.

1905. Hartshorne, Wm. D., Arlington Mills, Methuen, Mass., U.S.A., Agent.

1901. Hartwell, S. Warren, 120, North Fourth Street, Easton, Pa., U.S.A., Chemist.

1908. Harvey, Arthur J., 265, Burdett Road, Limehouse, E., Chemist.

1885. Harvey, Ernest W., 36, Arthur Road, Wimbledon Park, London, S.W., A.R.S.M., Engineer.

1913. Harvey, Hildebrand W., Hutton Mount, Brentwood, Essex, Research Chemist.

1891. Harvey, Sidney, South-Eastern Laboratory, Canterbury, Analytical Chemist.

1899. Harvey, Thos. F., 69, North Road, West Bridgford, Nottingham. Analyst (Drug Co.).

1883. Harvey, T. H., Cattedown, Plymouth, Chemical Manufacturer.

1908. Harvey, Wm. Ross, c/o R. Lehmann and Co., Ltd., Peninsular House, Monument Street, London. E.C., Starch Manufacturer.

1903. Hasenclever, Max, Chemische Fabrik Rhenania, Aachen, Prussia, Chemical Manufacturer.

1906. Haskell, Walter F., 234, Bridge Street, Westbrook, Maine, U.S.A., Textile Chemist and Colourist.

1900. Haslwanter, Chas., 447, Spruce Street, Richmond Hill, Long Is., N.Y., U.S.A., Analytical Chemist.

1897. Hasslacher, Jacob, P.O. Box 1999, New York City, U.S.A., President, Roessler-Hasslacher Chemical Co.

1903. Hatschek, Emil, c/o S. Bornett and Co., Ltd., 19, St. Dunstan's Hill, London, E.C., Engineer.

1887. Hatton, Wm. P., c/o W. R. Hatton and Sons, Wormwood Scrubbs, W., Starch Works Manager.

1906. Havercroft, Arthur E., Glenholme, Westbourne Road, Hornsea, Yorks, Chemist.

1899. Hawdon, H. S., Cleadon, near Sunderland, Chemical Works Manager.

1895. Hawker, E. W., Gladstone Chambers, Adelaide, South Australia, Metallurgist.

1910. Hawkes, Cornelius A., 43, Painswick Road, Gloucester, Analytical Chemist.

1902. Hawkins, Clement C., c/o The Texas Co., Port Neches, Texas, U.S.A., Chemist.

1897. Hawkins, Ernest M., Watling Chambers, Canterbury, Analytical Chemist.

1905. Hawkins, Henry, Moyola Villa, Lansdown, Limerick, Ireland, Gas Engineer.

1893. Hawkins, J. Dawson, c/o U. S. Reduction and Refining Co., Colorado Springs, Colo., U.S.A., President and General Manager.

1887. Hawliczek, Josef, c/o United Alkali Co., Intelligence Dept., Widnes, Consulting Chemical Expert.

1899. Haworth, Dr. Edw., Ivy Bank, Moughland Lane, Runcorn, Cheshire, Chemist.

1903. Haworth, Herbert, Crown Works, Appley Bridge, near Wigan, Director (Grove Chemical Co.).

1910. Haworth, John, 117, Millhouses Lane, Sheffield, Chemist and Sewage Works Superintendent.

1904. Hawthorn, J. H., Municipal Technical School, Leicester, Head Master.

1914. Hay, George S., 55, Shrubland Road, Hoe Street, Walthamstow, N.E., Analytical Chemist.

1910. Hay, J. Gordon, 37, Worcester Road, Bootle, Liverpool, Analytical Chemist.

1913. Hay, J. Thomas, Research Dept., Stark Rolling Mill Co., Canton, Ohio, U.S.A., Director.

O.M. Haydn-Morris, J., 22, Largo das Fontanhas, Lisbon, Portugal, Technical Chemist.

1900. Haydock, A. G., c/o The Castner-Kellner Alkali Co., Wallsend-on-Tyne, Technical Chemist.

1909. Haydon, James R., 91, Ampthill Road, Aigburth, Liverpool, Works Manager and Chemist.

1894. Haynes, David O., 82, Fulton Street, New York City, U.S.A., Proprietor, "Pharmaceutical Era."

1902. Hays, B. F., c/o E. R. Squibb and Sons, 80, Beekman Street, New York City, U.S.A., Pharmaceutical Chemist.

1906. Hayworth, W. P., 24, Tower Road, Dartford, Kent, Chemist.

1905. Hazard, Fred R., P.O. Box 2, Syracuse, N.Y., U.S.A., President (Solvay Process Co.).

1903. Hazen, Chas. R., 258, Prince Albert Avenue, Westmount, Quebec, Canada, Chemist.

1894. Heal, Carlton B., Hill Crest, Runcorn, Cheshire, Tanner.

1912. Healey, E., jun., St. Mary's Mills, Leicester, India-rubber Manufacturer.

1913. Heath, Geo. M., 787, Sherbrooke Street West, Montreal, Canada, Flour Mill Superintendent.

1905. Heathcote, Henry L., c/o Rudge-Whitworth, Ltd., Coventry, Research Chemist.

1904. Heaton, Noel, 72, Abbey Road, London, N.W., Colour Manufacturer.

1905. Heberlein, Dr. Edw., c/o H. T. Enthoven and Sons, Ltd., 247, Rotherhithe Street, London, S.E., Works Manager.

1889. Hecht, Jos. L., c/o French and Hecht, Davenport, Iowa, U.S.A., Analytical Chemist.

1900. Heckman, J. Conrad, Larkin Soap Manufacturing Co., Seneca Street, Buffalo, N.Y., U.S.A., Chemist.

1914. Hector, Alex. B., c/o Burroughs, Wellcome and Co., 481, Kent Street, Sydney, N.S.W., Australia, Manager.

1885. Hedley, Armorer, Durrant House, Bournemouth, Hants.

1912. Hedley, Dr. Edgar P., Cape Explosives Works, Somerset West, C.C., South Africa, Chemist.

O.M. Hehner, Otto, 11, Billiter Square, London, E.C., Analytical and Consulting Chemist.

1908. Heilmann, Dr. Ernst, Güstrow, Mecklenburg, Germany, Chemical Manufacturer.

1887. Hellier, E. A., Avonside Varnish Works, St. Philip's Marsh, Bristol, Varnish Manufacturer.

1885. Hellon, Dr. R., 40, New Lowther Street, Whitehaven, Analytical and Consulting Chemist.

1903. Helps, D. H., c/o Reading Gas Co., King's Road Works, Reading, Engineer and Manager.

1898. Hemingway, Frank C. R., 17, Battery Place, New York City, and (Journals) 6, East Union Avenue, Bound Brook, N.J., U.S.A., Chemical Manufacturer.

1883. Hemingway, H., 9, Albemarle Mansions, Hampstead, N.W., Chemical Manufacturer.

1903. Hemstreet, George P., Hastings-on-Hudson, N.Y., U.S.A., Mechanical Engineer.

1910. Henderson, Ernest G., c/o Canadian Salt Co., Ltd., Windsor, Ont., Canada, Vice-President and Manager.

1883. Henderson, Prof. G. G., Royal Technical College, George Street, Glasgow, Professor of Chemistry.

1902. Henderson, Prof. Jas. A. Russell, Stranord, West Kilbride, Ayrshire, Professor of Chemistry and Physics.

1894. Henderson, Jos., Eskbank Ironworks, Lithgow, N.S.W., Australia, Blast Furnace Manager.

1894. Henderson, Norman M., Broxburn Lodge, Broxburn, Scotland, Oil Works Manager.

O.M. Henderson, W. F., Moorfield, Claremont Gardens, Newcastle-on-Tyne.

1893. Hendrick, Prof. Jas., Marischal College, Aberdeen, Professor of Agriculture.

1906. Henius, Dr. Max, 1135—1147, Fullerton Avenue, Chicago, Ill., U.S.A., Secretary, Brewers' School.

1912. Henley, Andrew T., Lady's Well Brewery, Cork, Ireland, Technical Chemist.

1904. Henley, Hon. F. R., 9, Beaufort Gardens, London, S.W., Brewers' Chemist.

1905. Henning, Albert, c/o Hedley and Co., 92, Harrow Road, Leytonstone, N.E., Ester Manufacturer.

1906. Henning, C. I. B., c/o E. I. du Pont de Nemours Powder Co., Experimental Station, P.O. Henry Clay, Del., U.S.A., Chemist.

1914. Henshaw, D. M., c/o W. C. Holmes and Co., Ltd., Whitestone Ironworks, Huddersfield, Chemical Engineer.

1894. Henshaw, Sam., Glenthorne, Wolstanton, Stoke-on-Trent, Chemical Works Manager.

1910. Hepburn, Edward, Priory Works, Dartford, Kent, Tanner.

1888. Hepworth-Collins, W., Junior Constitutional Club, Piccadilly, London, W.; retain Journals, Civil Engineer.

1906. Herig, Harry W., c/o General Chemical Co., Hudson River Works, Edgewater, N.J., U.S.A., Chemist.

1897. Heriot, T. H. P., Royal Technical College, Glasgow, Lecturer in Sugar Manufacture.

O.M. Herman, W. D., Holm Lea, Rainhill, Lancashire, Glass Works Chemist.

1903. Herreshoff, J. B. F., 620, West End Avenue, New York City, U.S.A., Chemical Engineer.

1887. Herriot, Wm. Scott, Clarewood, Thorntonhall, Lanarkshire, Mechanical Engineer.

O.M. Herrmann, R. W., 59, Mark Lane, London, E.C., Chemical Merchant.

1891. Hersam, Ernest A., University of California, Berkeley, Cal., U.S.A., Associate Professor of Metallurgy.

1898. Hersey, Dr. Milton L., P.O. Box 1086, Montreal, Canada, Consulting Chemist.

1903. Herstein, Dr. Bernard, Insular Collector of Customs, Manila, Philippines.

1906. Herty, Prof. Chas. H., University of N. Carolina Chapel Hill, N.C., U.S.A., Professor of Chemistry.

1906. Herz, Dr. Albert, c/o John Crossley and Sons, Ltd., Halifax, Yorks, Chemist.

1907. Hess, Arthur F., c/o A. Hess and Bro., Ltd., Kirkstall Road, Leeds, Oil Distiller.

1905. Hesse, Dr. Bernhard C., 90, William Street, New York City, U.S.A., Chemist.

1891. Hetherington, Dr. Albert E., Ammonia Soda Works, Fleetwood, Lancashire, Analytical Chemist.

1904. Heurich, Christian, 1307, New Hampshire Avenue, N.W., Washington, D.C., U.S.A., Brewer.

1894. Hewitt, A. H., The Green Island Cement Co., Ltd., Hong Kong, China, Engineer.

1910. Hewitt, Arthur, c/o Consumers' Gas Co., 19, Toronto Street, Toronto, Canada, General Manager.

O.M. Hewitt, Dr. D. B., 28, Queen's Gardens, Hyde Park, London, W., Alkali Manufacturer.

1896. Hewitt, Dr. J. Theo., F.R.S., Clifford House, Bedfont, Middlesex, Lecturer.

1890. Hewlett, John C., 40—42, Charlotte Street, Great Eastern Street, London, E.C., Manufacturing Chemist.

1907. Hewson, Geo. W., Grasmere, Field Terrace, Jarrow-on-Tyne, Analytical Chemist.

1893. Hey, Harry, 2, Ash Terrace, Savile Town, Dewsbury, Dyer.

1894. Heyl, G. Edward, King's House, Kingsway, London, W.C., Chemical and Electrical Engineer.

1906. Heys, Charles H., Toronto Arcade, Toronto, Canada, Consulting Chemist.

1901. Hiby, Dr. Walter, c/o The Otto Hilgenstock Coke Oven Co., Ltd., Post Office House, Leeds, Chemical Engineer.

1906. Hicking, W. Norton, Queen's Road Works, Nottingham, Lace Dresser.

1906. Hickman, T. Moore, Holmdale, Penn Road, Wolverhampton, Analyst.

1897. Hicks, Edwin F., 4837, Fairmount Avenue, Philadelphia, Pa., U.S.A., Analytical Chemist.

O.M. Higgin, W. H., c/o C. J. Schofield, Ltd., Alkali Works, Clayton, Manchester, Chemical Manufacturer.

1913. Higgins, A. Howard, Estrella, Hale Lane, Mill Hill, N.W., Metallurgist.

1886. Higgins, C. L., 41, Knowsley Road, Cressington Park, Liverpool, Manufacturing Chemist.

1905. Higgins, Dr. Eric, 12, Elleray Park Road, Wallasey, Cheshire, Chemist.

1905. Higgins, John M., 39, Queen Street, Melbourne, Vic.; Australia,, Consulting Metallurgist.

1908. Higgins, S. H., Luncarty Bleachfield, Perth, Chemist and Asst. Manager.

1909. Higson, Frank, 52, Chapel Street, Salford, Manchester, Analytical Chemist.

1909. Higuchi, Ken-ichi, Central Laboratory, South Manchuria Railway Co., Dairen, Manchuria, Chemical Engineer.

1911. Hilditch, T. P., Birchdene, Cross Lane, Grappenhall, Warrington, Research Chemist.

1903. Hill, Chas. Alex., c/o British Drug Houses, Ltd., 22—30, Graham Street, City Road, N., Chemist.

1897. Hill, Dr. Herbert M., 20, West Eagle Street, Buffalo, N.Y., U.S.A., City Chemist.

1907. Hill, James A., Technical Chemist.

1908. Hill, J. H. F., c/o Broken Hill Proprietary Co., Broken Hill, N.S.W., Australia, Mining Engineer.

O.M. Hill, J. K., 13, Osborne Place, Ibrox, Glasgow, Manufacturing Chemist.

1892. Hill, Sydney, c/o Blundell, Spence, and Co., Ltd., Hull, Analytical Chemist.

1903. Hill, W. Basil, Foss Islands Tannery, York, Tanner.

1902. Hill, Wm. G., jun., c/o Apsley Rubber Co., Hudson, Mass., U.S.A., Chemist.

1898. Hill-Jones, Thos., Invicta Mills, Bow Common Lane, London, E., Manufacturing Chemist.

1894. Hills, Harold F., Commercial Gas Works, Stepney, London, E., Analytical Chemist.

O.M. Hills, W., Oxford Works, Tower Bridge Road, London, S.E., Pharmaceutical Chemist.

1899. Hinchley, J. W., 55, Redcliffe Road, London, S.W., Chemical Engineer.

1904. Hinckley, J. F., 550, East 7th Street, Brooklyn, N.Y., U.S.A., Chemical Engineer.

O.M. Hindle, J. H., 8, Cobham Street, Accrington, Dyeworks Manager.

1909. Hinks, Edward, 16, Southwark Street, London, S.E., Analyst.

1899. Hinks, Percy J., Danger Building Dept., Royal Laboratory, Woolwich Arsenal, S.E., Chemist.

1891. Hinman, Bertrand C., Coventry House, South Place, Finsbury, London, E.C., Metallurgical Chemist.

1912. Hinman, Jack J., jun., 507, East Eleventh Street, Indianapolis, Ind., U.S.A., City Analyst.

1909. Hirsch, Fritz, 51, Ferndale Avenue, Wallsend-on-Tyne, Analytical Chemist.

1914. Hirschberg, Dr. Leon, 46, Farringdon Street, London, E.C., Chemical Engineer.

1914. Hirst, A. Norman, Box 1106, Durban, South Africa, Consulting Chemist.

1895. Hirst, H. Reginald, Bank House, Staincliffe, Batley, Yorks, Works Chemist.

1907. Hirt, Wilhelm B., c/o Cuming, Smith, and Co., Ltd., Yarra Junction, Vic., Australia, Analytical Chemist.

1907. Hirtz, Dr. Heinrich, Chemist.

1896. Hislop, Geo. R., (Journals) Gas Works, (communications) Greenhill House, Underwood Road, Paisley, Gas Engineer and Manager.

1913. Hitchcock, Thos. J., 28, Albany Road, Manor Park, Essex, Technical Chemist.

1900. Hobbs, Alex. F., c/o The United States Finishing Co., Box A., North Station, Providence, R.I. U.S.A., Printworks Superintendent.

1905. Hobson, Alfred, Dantzic Brewery, Imperial Street, Regent Street, Leeds, Brewer and Wine Manufacturer.

1909. Hodgart, Matthew, Vulcan Works, Paisley, Engineer.

1894. Hodge, Andrew, Glenariff, Whaley Bridge, near Stockport, Printworks Chemist.

1913. Hodgetts, E. A. Brayley, Nobel Dynamite Trust, 220, Winchester House, Old Broad Street, London, E.C., Secretary.

O.M. Hodgkinson, Dr. W. R., 89, Shooter's Hill Road, Blackheath, S.E., Professor of Chemistry.

O.M. Hodgson, Chris., 33, Oakdale Road, Nether Edge, Sheffield, Metallurgical Chemist.

1913. Hodgson, Cyril V., 52, London Road, Chesterton, North Staffordshire, Works Chemist.

1897. Hodgson, Matthew, Ardmore, Church Hill, Wicklow, Ireland, Technical Chemist.

1890. Hodgson, Wm., 66, Deansgate, Manchester, Oil and Colour Broker.

1910. Hodsman, Henry J., Dept. of Fuel and Coal Gas Industries, The University, Leeds, Chemist.

1906. Hogarth, Julius W., The University, Sydney, N.S.W., Australia, Demonstrator of Chemistry.

1886. Hogben, W., Post Office, Port Talbot, South Wales, and (Jul.) Malvern House Hotel, Great Malvern, Chemical Expert (Celluloid, etc.).

O.M. Hogg, T. W., c/o John Spencer and Sons, Newburn Steelworks, Newcastle-on-Tyne, Metallurgical Chemist.

1905. Holcroft, Harold, Parkdale, Wolverhampton, Ironfounder.

1899. Holden, Archie Neill, c/o Hardman and Holden, Ltd., Miles Platting, Manchester, Chemist.

1887. Holden, G. H., Manchester Oxide Co., Ltd., Canal Street, Miles Platting, Manchester, Chemist.

1904. Holden, Norman N., c/o Hardman and Holden, Ltd., Miles Platting, Manchester, Manufacturing Chemist.

1902. Holdsworth, Ernest T., "Holme Dene," Crossley Hall, Bradford, Dyer.

1885. Holgate, T. E., 173, Hollins Grove, Darwen, Lancashire, Metallurgist.

1884. Holgate, Thos., 61, Calton Road, Dulwich, S.E., Gas Engineer.

O.M. Holland, Philip, 22, Taviton Street, Gordon Square, London, W.C., Analytical Chemist.

1892. Holland Philip H., 546, Sherbrooke Street West, Montreal, Canada, Merchant.

1909. Holliday, F. E., 81, Fulton Street, New York City, U.S.A.

1896. Hollings, J. Spencer, Brymbo, North Wales, Works Manager.

1909. Hollingworth, David V., Birchenwood Collieries, Kidsgrove, Stoke-on-Trent, Gas Analyst.

1903. Hollinshead, Peter, The Beeches, Weston Road, Runcorn, Cheshire, Chemist.

1900. Hollinshead, Dr. Warren H., Wingrove Avenue, Nashville, Tenn., U.S.A., Teacher of Chemistry.

1904. Holloway, E. G., c/o Jas. S. Kirk and Co., 360, North Water Street, Chicago, Ill., U.S.A., Chemist.

1890. Holloway, G. T., 9–13, Emmett Street, Limehouse, London, E., Consulting Chemist and Metallurgist.

1883. Holmes, Ellwood, Wyncote, Jesmond Park East, Newcastle-on-Tyne, Colour Manufacturer.

O.M. Holmes, F. G., Thames Tar Works, Lower Road, Northfleet, Kent, Tar and Ammonia Distiller

1914. Holroyd, Thomas A., Carnatic House, Perambore Barracks, Madras, India, Colour Chemist.

1913. Holt, Dr. Alfred, Dowsefield, Allerton, Liverpool, University Reader in Physical Chemistry.

1900. Holthouse, Harold B., 106, Radcliffe Road, West Bridgford, Notts, Chemist.

1902. Holton, Alf. L., Chemical Dept., Gas Works, Bradford Road, Manchester, Chemist.

1892. Holton, E. C., 601, Canal Road N. W., Cleveland, Ohio, U.S.A., Chemist.

1893. Holzapfel, Max, c/o Holzapfels, Ltd., Felling-on-Tyne, Manufacturer.

1893. Homfray, D., c/o La Fabrica de Papel, San Rafael, Est. de Mexico, Mexico, Analytical Chemist.

1909. Hook, Russell W., 8, Holton Street, West Medford, Mass., U.S.A.

1904. Hooker, A. H., c/o Hooker Electrochemical Co., Niagara Falls, N.Y., U.S.A., Manufacturing Chemist.

O.M. Hooper, E. Grant, 16, Royal Avenue, Sloane Square, London, S.W., Chemist.

1889. Hooper, Ernest F., c/o Brotherton and Co., Ltd., Wear Tar Works, South Dock, Sunderland, Technical Chemist.

1888. Hope, Jas., The Knoll, Lenzie, near Glasgow, and (Journals) The Nickel Co., Kirkintilloch, by Glasgow, Nickel Works Manager.

1904. Hopewell, Fredk., 59, William Street, Montreal, Canada, Manager.

1892. Hopkins, Erastus, Geneva, N.Y., U.S.A., Consulting Chemist.

1905. Hoppenstedt, A. W., c/o Schoellkopf and Co., Perry and Mississippi Streets, Buffalo, N.Y., U.S.A., Chemist.

1911. Hord, Arthur R., c/o W. H. Holmes and Sons, Portland Road, Newcastle-on-Tyne, Analytical Chemist.

1895. Horne, Dr. W. D., 175, Park Avenue, Yonkers, N.Y., U.S.A., Consulting Chemist

1904. Hornsey, J. W., 233, Broadway, New York City, U.S.A., and (Journals) Searles, Cal., U.S.A., Chemical Engineer.

1913. Horrocks, Herbert, 253, Jelliff Avenue, Newark, N.J., U.S.A., Chemist.

1900. Horsfall, Jno., 4, Grange Avenue, Rawtenstall, Manchester, Analytical and Consulting Chemist.

1901. Horton, Edw., jun., Rothamsted Experimental Station, Harpenden, Herts, Chemist.

1906. Hoseason, Jas. H., Sun Buildings, 2, Bridge Street, Manchester, Chemical Manufacturer.

1890. Hoskins, A. Percy, Clonlee, Rosetta Park, Belfast, Ireland, Analytical Chemist.

1899. Hoskins, Wm., 2009, Harris Trust Building, 111, West Monroe Street, Chicago, Ill., U.S.A., Chemist.

1914. Hough, Alex. T., Telok Ayer, Pontianak, Dutch West Borneo, Chemist.

1911. Hough, Samuel, c/o Lever Bros., Ltd., Balmain, Sydney, N.S.W., Australia, Chemist.

1899. Houlder, Bertram E., 50, Lady Margaret Road, Southall, Middlesex, Chemist.

1892. Houston, John, 30, Princess Street, Manchester, Drysalter.

O.M. Howard, A. G., Burnt House, Chigwell, Essex, Chemical Manufacturer.

1901. Howard, Bernard F., Firbank, Loughton, Essex, Chemist.

O.M. Howard, D., Devon House, Buckhurst Hill, Essex, Chemical Manufacturer.

1887 Howard, D. Lloyd, Uphall Works, Ilford, Essex, Chemical Manufacturer.

1898. Howard, Henry, 36, Amory Street, Brookline, Mass., U.S.A., Chemical Engineer.

1902. Howard, Nelson A., c/o General Chemical Co. of California, 705, Royal Insurance Building, San Francisco, Cal., U.S.A., General Manager.

1913. Howard, Tom, 57, Grey Street, Stalybridge, Cheshire, Chemist.

1906. Howe, Chester A., 124, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.

1903. Howe, Jas. Lewis, Washington and Lee University, Lexington, Va., U.S.A., Professor of Chemistry.

1912. Howe, Dr. Percy R., 536, Pleasant Street, Belmont, Mass., U.S.A., Dentist.

1904. Howell, Walter L., Room 314, Custom House, New Orleans, La., U.S.A., Chemist.

1899. Howles, Fred., c/o McDougall Bros., 66—68, Port Street, Manchester, Chemist.

1889. Howorth, F. Wise, 10, New Court, Lincoln's Inn, W.C., Technical Chemist and Chartered Patent Agent.

1907. Howroyd, Richard R., c/o Calder Mersey Extract Co., Ltd., Ditton, near Widnes, Chemist.

1914. Howson, Herbert G., 286, New Chester Road, Port Sunlight, Birkenhead, Analytical Chemist.

1906. Hoyler, Fritz, 93, Market Street, Perth Amboy, N.J., U.S.A., Chemist.

1896. Hoyte, Percy S., Gas Works, Coxside, Plymouth, Gas Engineer.

1900. Hübner, Julius, Linden, Cheadle Hulme, Cheshire, Director of Dyeing and Papermaking Departments (Municipal School of Technology).

1909. Hudson, Baker, Public Library, Middlesbrough, Librarian.

1899. Hudson, Dr. Edw. J., c/o Pioneer Iron Co., Marquette, Mich., U.S.A., Chemist.

1905. Hudson, O. F., The University, Edgbaston, Birmingham, Lecturer on Metallurgy.

O.M. Hughes, J., 79, Mark Lane, London, E.C., Agricultural Chemist.

1908. Hughes, Wm. E., Chemical Laboratory, Messrs. W. Canning and Co., Great Hampton Street, Birmingham, Electro Chemist.

1906. Hulme, Robert B., 1162, Union Avenue, Memphis, Tenn., U.S.A., Chemical Engineer and Manager.

1909. Hultman, G. H., St. Paulsgatan 31, Stockholm, Sweden, Gas Engineer.

1905. Hulton, H. F. E., 15, Oak Hill Court, Putney, S.W., Chemist.

1905. Humel, Edward J., 13315, Detroit Street, Lakewood, Cleveland, Ohio, U.S.A., Chemist.

1893. Humfrey, Chas., Hilderstone, Hartford, Cheshire, Alkali Works Manager.

1902. Humphrey, Richard L., 1001, Harrison Building, Philadelphia, Pa., U.S.A., Civil Engineer.

1903. Humphreys, A. C., 165, Broadway, New York City, and (Jnls.) Stevens Inst. of Technology, Hoboken, N.J., U.S.A., Engineer.

1913. Humphreys, Dr. R. E., 229, Laporte Avenue, Whiting, Ind., U.S.A., Chemist.

1908. Humphries, Albert E., Coxes Lock Mill, Weybridge, Surrey, Flour Miller.

1912. Humphries, Herbert B. P., Queen Anne's Chambers, Westminster, S.W., Consulting Chemist.

O.M. Humphrys, N. H., Gasworks, Salisbury, Wilts., Gas Engineer.

1900. Hunt, Arthur V., 19, Park Road, Port Sunlight, Cheshire, Analytical Chemist.

O.M. Hunt, Chas., 17, Victoria Street, Westminster, London, S.W., Civil Engineer.

1909. Hunt, Edwin J., The Grange, Walsall, Staffs. Managing Director, Chance and Hunt, Ltd.

1883. Hunt, J. S., Appleton, Widnes.

1903. Hunt, P. C. Holmes, Metropolitan Gas Co., Flinders Street, Melbourne, Vic., Australia, Gas Engineer.

O.M. Hunt, W., Hampton House, Wood Green, Wednesbury, Staffordshire, Chemical Manufacturer.

1893. Hunter, Prof. Matthew, Rangoon College, Rangoon, Burmah, Professor of Chemistry.

O.M. Huntington, Prof. A. K., King's College, Strand, London, W.C., Professor of Metallurgy.

1902. Huntly, Geo. N., 14, Old Queen Street, Westminster, S.W., Analytical and Consulting Chemist.

1904 Hurren, F. H., c/o The Rover Co., Ltd., Coventry, Analytical Chemist.

1894. Hurry, E. H., Llanover, Churt, Farnham, Surrey, Mechanical Engineer.

1894. Hutcheson, Jno. F., 39, St. Enoch Square, Glasgow, Chemical Manufacturer.

1912. Hutchin, C. D., c/o Messrs. Meredith and Drew, Ltd., High Street, Shadwell, London, E., Biscuit Manufacturer.

1900. Hutchinson, E. George, Gas Works, Carlisle, Manager.

O.M. Hutchinson, T. J., Aden House, Manchester Road, Bury, Analytical and Consulting Chemist.

1909. Hutchison, Chas. F., Eastman Kodak Co., Kodak Park, Rochester, N.Y., U.S.A., Photographic Emulsion Maker.

1909. Hütz, Dr. R., 32, India Street, Boston, Mass., U.S.A., Colour Chemist.

O.M. Huxley, Jas. H., c/o Vickers, Son, and Maxim, Ltd., River Don Works, Sheffield, Metallurgical Chemist.

1906. Huyett, Miles C., 1005, Morgan Building, Buffalo, N.Y., U.S.A., Mechanical Engineer.

1897. Hyams, Godfrey M., 312, Sears Building, Boston, Mass., U.S.A., Mines Manager.

1902. Hyde, Austin T., Box 98, Rumford Falls Maine, U.S.A., Chemical Engineer.

1897. Hyde, B. T. Babbitt, 11, Broadway, New York City, U.S.A., Soap Manufacturer.

1899. Hyde, Fred. S., 215, Schermerhorn Street, Brooklyn, N.Y., U.S.A., Research Chemist.

1899. Hyde, Wm. Grantley, Garden Wharf, Church Road, Battersea, S.W., Assayer.

1901. Hyman, Leonard W., 342, South Pearl Street, Albany, N.Y., U.S.A., Analytical Chemist.

I

1912. Ibbotson, E. C., 28, Westwood Road, Porter Glen, Sheffield, Steel Manager.

1900. Ichioka, Dr. Tajiro, 19, Maruyama, Shinmachi, Hongo, Tokio, Japan, Chemist (Imperial Japanese Navy).

1906. Iddings, Richard P., Arlington Mills, Lawrence, Mass., U.S.A., Chemist.

1885. Idris, T. H. W., M.P., 120, Pratt Street, Camden Town, N.W., Mineral Water Manufacturer.

1913. Illingworth, S. R., c/o Gas Lighting Improvement Co., Ltd., Pacific Wharf, West Ham, E., Works Chemist.

1909. Imison, C. S., The Cottage, Runcorn, Cheshire, Chemist, United Alkali Co.

1900. Imrie, John, 83, Horndean Road, Firth Park, Sheffield, Producer Gas and By-Products Plant Manager.

1900. Ingalls, Walter R., 505, Pearl Street, New York City, U.S.A., Mining Engineer and Metallurgist.

1889. Ingle, Dr. Harry, 6, Highfield Terrace, Kingston Road, Leeds, Organic Chemist.

1909. Ingleby, G. W., c/o John L. Seaton and Co., Ltd., Sculcoates, Hull, Director.

1906. Inglis, Dr. Jno. K. H., University of Otago, Dunedin, New Zealand, Professor of Chemistry.

1912. Inglis, Robert J. C., Chicago House, Cliffe at Hoo, Kent, Analytical Chemist.

1911. Innes, Dr. Alfred G., Fabrique de Soie Artificielle, Tubize, Belgium, Technical Chemist.

1909. Innes, R. Faraday, c/o The British Chrome Tanning Co., St. Andrew's Tannery, Northampton, Chemist.

1906. Innes, Dr. Wm. Ross, 19, St. James' Avenue, Cricklewood, N.W., Chemist.

1910. Irvine, Prof. J. C., Chemical Research Laboratory, The University, St. Andrews, Scotland, Professor of Chemistry.

1884. Irving, J. M., 17A, Dickinson Street, Cooper Street, Manchester, Chemical Merchant.

1911. Irwin, George C., c/o S. H. Johnson and Co., Ltd., Carpenter's Road, Stratford, E., Manager (Engineering Works).

O.M. Irwin, W., Derwent Lodge, Cockermouth, Analytical Chemist.

1901. Isakovics, Alois von, Synfleur Scientific Laboratories, Monticello, N.Y., U.S.A., Manufacturing Chemist.

1900. Ittner, Dr. Martin H., c/o Colgate and Co., Jersey City, N.J., U.S.A., Soap and Essential Oil Chemist.

1912. Ivatt, Albert, The Engadine, Histon, Cambridge, Chemist (Foods).

1908. Ives, Herbert, 125, Pearl Street, Boston, Mass., U.S.A., Manager (Dyestuffs, etc.).

J

1890. Jackman, E. J., 60, Belgrave Road, Ilford, Essex, Technical Chemist.

O.M. Jackson, Edward, Raven's Cliff, Oxford Road, Moseley, Birmingham, Alkali Works Inspector.

1904. Jackson, Ernest W., Godrevy, Saltburn, Yorks, Analytical Chemist.

1891. Jackson, F., Smedley Bridge Works, Cheetham, near Manchester, Bleacher and Dyer.

1883. Jackson, Frederick, 14, Cross Street, Manchester, Laboratory Furnisher.

1886. Jackson, John, 98, Dobbie's Loan, Glasgow, Lubricant Manufacturer.

1901. Jackson, Percy G., c/o National Boiler Insurance Co., St. Mary's Parsonage, Manchester, Chemist.

1890. Jackson, Saml., 3, Buckingham Gardens, Perambore Barracks, Madras, N., India, Analytical Chemist.

1902. Jackson, Samuel, c/o Wm. Metcalf, Ltd., Church, near Accrington, Director (Tar Distillery).

1898. Jackson, Thos., Thornton View, Clayton, Manchester, Chemical Manufacturer.

1900. Jackson, Victor G., 17, Doughty Street, London, W.C., Chemist.

1900. Jackson, Dr. W. Hatchett, Radcliffe, Library, Oxford, Librarian and Science Tutor (Keble College).

1893. Jackson, Rt. Hon. W. L., F.R.S. *See* Allerton, Rt. Hon. Lord.

1899. Jackson, W. Morton, c/o British Oxygen Co., Ltd., Great Marlborough Street, Manchester, Manager.

O.M. Jackson, W. P., Saxilby, near Lincoln, Chemical Works Manager.

1900. Jacoby, Areli H., c/o American Dyewood Co., 80, Maiden Lane, New York City, U.S.A., Chemist.

1900. Jäger, B. M., c/o Geo. Jäger and Sons, 77, Burlington Street, Liverpool, Sugar Chemist.

1886. Jago, Wm., 1, Garden Court, Temple, London, E.C., Barrister at-Law,

1883. James, E. T., British Alizarin Co., Ltd., Silvertown, Victoria Docks, E., Secretary.

1893. James, Lawrence S., 28, Corona Street, Dorchester Center, Mass., U.S.A., Gas Inspector.

1905. James, Oscar S., 227, George Street, Toronto, Canada, Analytical Chemist.

1890. Jarmain, Geo. S., Dalton Lodge, Huddersfield, Wool Extractor.

O.M. Jarmay, G., Hartford Lodge, Hartford, Cheshire, Alkali Manufacturer.

1911. Jarrom, Harry G., 41, Wilberforce Road, Hendon, N.W., Managing Director (Gallenkamp and Co.).

1900. Jarvie, Jas., Ferndale, Kenmure Avenue, Bishopbriggs, Scotland, Chemist.

1907. Jatar, S. B., 219, Upper Brook Street, C. on M., Manchester, Student.

1914 Jaubert, Dr. Geo. F., 155, Boulevard Malesherbes, Paris, France, Technical Journalist.

1910. Jayne, David W., c/o Barrett Manufacturing Co., Frankford, Philadelphia, Pa., U.S.A., Manager.

1913. Jeans, Harold, 165, Strand, London, W.C., Metallurgist.

1908. Jeffery, John H., 10, Daysbrook Road, Streatham Hill, London, S.W., Chemist and Metallurgist.

1892. Jenkin, W. A., 5, Bella Vista, Minas de Rio Tinto, Provincia de Huelva, Spain, Metallurgical Chemist.

1905. Jenkins, Chas. D., 59, North Street, Newtonville, Mass., U.S.A., Chemist.

1894. Jenkins, John H. B., Laboratory, G.E.R. Works, Stratford, E., Analytical Chemist.

1912. Jenkins, Leslie C. W., 26, Ulundi Road, Blackheath, S.E., Chemist (Wood Dyeing).

1912. Jenkins, Rees, The White Cottage, Foleshill, Coventry, Analytical Chemist.

1894. Jenks, Robt. L., 1, Chamock Place, Calcutta, India, Chemist.

1911. Jennens, John H., 4, Highbridge Road, Wylde Green, nr. Birmingham, Analytical Chemist.

1908. Jennison, George, Beechwood, Tatton Road South, Heaton Moor, Stockport, Chemist.

1905. Jennison, Jas., Mountfield, London Road, Greenhithe, Kent, Chemist.

1904. Jepson, John Elliott, c/o Star Paper Mill Co., Ltd., Feniscowles, near Blackburn, Chemist.

1899. Jerdan, Dr. David S., Temora, Colinton, Midlothian, Chemist (Gelatin Works).

1899. Jessop, Louis V., Holmlea, 23, Woodville Road, Leytonstone, Essex, Chemist.

1904. Jewson, F. T., Earith, near St. Ives, Hunts, Chemist.

1896. Job, Robt., 649, Roslyn Avenue, Westmount, Quebec, Canada, Analytical Chemist.

1906. John, David, Haileybury, Ontario, Canada, Chemist.

1908. Johnson, Arthur, 25, Nursery Street, Pendleton, Manchester, Chemist.

1886. Johnson, A. E., 24, Parkdale, Wolverhampton, Analytical Chemist.

1904. Johnson, Cedric, Winnintgon Park, Northwich, Cheshire, Chemical Engineer.

1891. Johnson, Edmond E., c/o Adcocks, Drayton Park Works, Highbury, N., Chemical Engineer.

1904. Johnson, Dr. F. M. G., 286, Peel Street, Montreal, Canada, Chemist.

1904. Johnson, G. B., 7, Church Street, Liverpool, Wholesale Chemist.

1907. Johnson, H. Finnis, c/o Borax Consolidated, Ltd., 16, Eastcheap, London. E.C., Sales Manager.

O.M. Johnson, J. E. J., 133, Earlham Grove, Forest Gate, E., Manufacturing Chemist.

1895. Johnson, Jesse F., P.O. Box 94, St. Anne de Bellevue, Quebec, Canada, Chemical Engineer.

1900. Johnson, John, c/o John Johnson and Co., 37th Street and Second Avenue, Brooklyn, N.Y., U.S.A., Chemical Engineer.

1913. Johnson, J. Carroll, 9, Well Road, Hampstead, N.W., Chemist.

1900. Johnson, Jno. W. Haigh, West Riding Rivers Board, Wakefield, Yorks, Chemist.

1906. Johnson, Oliver L., c/o The Aspinook Co., Jewett City, Conn., U.S.A., Dye Works Manager.

1904. Johnson, S. Hearon, 7, Church Street, Liverpool, Wholesale Chemist.

1895. Johnston, Alex. R., 18, Percy Street, Ibrox, Glasgow, Analytical Chemist.

1906. Johnston, A. McA., Box 108, Germiston, Transvaal, Metallurgical Chemist.

1894. Johnston, G. Lawson. *See* Lawson-Johnston, G.

1904. Johnston, J. H., 8, Leopold Road, Wimbledon, S.W., Chemist and Bacteriologist.

1904. Johnston, Thos. J., 4, Garrioch Drive, Maryhill, Glasgow, Chemist.

1890. Johnston, Wm. A., The S. S. White Dental Manufacturing Co., Prince Bay, N.Y., U.S.A., Dental Enamel Manufacturer.

1894. Johnston, W. E. Lawson. *See* Lawson-Johnston, W.E.

O.M. Johnston, Wm. G., Anchor Chemical Works, 1005, Garngad Road, Glasgow, Technical Chemist.

1910. Johnstone, E. J., Watertown, N.Y., U.S.A., Consulting Engineer and Industrial Chemist.

O.M. Johnstone, Jas., Shawfield Works, Rutherglen, Glasgow, Technical Chemist.

1905. Johnstone, J. Swanston, Meridian Drug and Essence Co., Bond Street, Durban, Natal, Distiller.

1903. Johnstone, S. J., 15, Springfield Road, New Southgate, N., Research Chemist.

1907. Jolliffe, Ernest H., Technical High School, 149, College Street, Toronto, Canada, Works Chemist.

1905. Jolliffe, Frank, 51, Vancouver Road, Forest Hill, S.E., Chemist.

1912. Jone, Hugo, 752, Broadway, Brooklyn, N.Y., U.S.A., Chemist.

1909. Jones, Arthur, c/o Grout and Co., Ltd., Silk Crape Works, Great Yarmouth, Technical Chemist.

1904. Jones, Arthur B., 981, Central Avenue, Plainfield, N.J., U.S.A., Superintendent.

1912. Jones, B. Vaughan, P.O. Box 27, Petersburg, Va., U.S.A., Chemist and Manufacturer.

1912. Jones, Charles, c/o Middleton Estate and Colliery Co., Ltd., Broom Pit, Leeds, Coke Plant Manager.

1902. Jones, David R., c/o Laurentian Chemical Co., Mont Tremblant, Quebec, Canada, Chemical Engineer.

1908. Jones, D. Trevor, "Mountain Ash," Ravenglass, Cumberland, Works Chemist.

1911. Jones, Edgar D., 3, Neville Road, Waterloo, near Liverpool, Analytical Chemist.

1912. Jones, E. Gabriel, City Analyst's Laboratories, Ashton Street, Liverpool, Assistant Public Analyst for Liverpool.

1910. Jones, E. Protheroe, The Golden Horseshoe Estates Co., Salisbury House, London Wall, London, E.C., Secretary.

1902. Jones, E. Strangways, Sulphide Corporation, Ltd., Cockle Creek, N.S.W., Australia, Metallurgical Chemist.

1909. Jones, E. Willis, 22, Coleshill Terrace, Llanelly, South Wales, Chemical Manufacturer.

O.M. Jones, E. W. T., 10, Victoria Street, Wolverhampton, Analytical Chemist.

1897. Jones, Fred. W., 35, Addiscombe Road, Croydon, Technical Chemist.

1896. Jones, G. Cecil, 41, London Road, Forest Hill, S.E., Consulting Chemist.

1912. Jones, G. P., Cameron Powder Manufacturing Co., Emporium, Pa., U.S.A., General Manager.

1905. Jones, Harold, Morro Velho, Villa Nova de Lima, Minas Geraes, Brazil, Analyst and Assayer.

1907. Jones, Henry Williams, 200, Gravelly Hill, Birmingham, Analytical Chemist.

1893. Jones, Herbert. *See* Sefton-Jones, H.

1901. Jones, Herbert J., 40, Reginald Road, Forest Gate, E., Chemist.

1910. Jones, Ivor R., 54, Atlantic Chambers, Manchester, Chemical Merchant.

1905. Jones, J. E. Stacey, Hearsall Works, Coventry, Consulting Chemist and Technical Metallurgist.

1904. Jones, J. Shirley, Moscow, Idaho, U.S.A., Chemist.

1914. Jones, Leonard S., 66, Leyspring Road, Leytonstone, N.E., Works Chemist.

1894. Jones, M. W., Stonebeck, Brislington, Bristol, Manager (Oil and Colour Works).

O.M. Jones, Walter Norris, Lancashire Metal Works, Widnes, Technical Chemist.

1903. Jones, Wm. App, c/o Boston Artificial Leather Co., 200, Fifth Avenue, New York City, U.S.A., Chemist.

1905. Jones, W. Ellis, 80, Arundel Avenue, Liverpool, Sugar Refiner.

1912. Jordan, Walter L., 918, West 5th Street, Glendale, Cal., U.S.A., Chemical Engineer.

1908. Joselin, Percy H., 81, Bennerley Road, New Wandsworth, S.W., Chemist.

1905. Joseph, A. F., Ceylon Technical College, Colombo, Ceylon, Lecturer on Chemistry.

1900. Josephson, Edgar, c/o Pantazote Leather Co., Passaic, N.J., U.S.A.

1906. Joshua, Dr. Walter P., c/o The Cape Copper Co., Ltd., Briton Ferry, South Wales, Chemist.

1891. Joslin, Omar T., 3223, Spring Grove Avenue, Cincinnati, Ohio, U.S.A., Chemical Engineer.

1887. Joüet, Dr. C. H., 238, East 2nd Avenue, Roselle, N.J., U.S.A., Technical Chemist.

1889. Journaud, Louis, Poot Evêque, près Vienne (Isère), France, Technical Chemist.

1904. Jowett, Dr. H. A. D., Phœnix Mills, Dartford, Kent, Research Chemist.

1903. Joyce, Clarence M., P.O. Box 23, Arlington, N.J., U.S.A., Chemist.

O.M. Justice, Philip M., 55-56, Chancery Lane, London, W.C., Patent Agent.

K

1896. Kalbfleisch, Franklin H., 31, Union Square West, New York City, U.S.A., Chemical Manufacturer.

1908. Kaliski, Dr. Maximilian S., 118, West 119th Street, New York City, U.S.A., Technical Chemist.

1884. Kalle, Dr. Wm., Biebrich-am-Rhein, Germany, Colour Manufacturer.

1912. Kampen, Kurt van, The London Electron Works, Ltd., Horseferry Road, Limehouse, E., Managing Director.

1913. Kastle, Dr. Joseph H., Kentucky Agricultural Experiment Station, Lexington, Ky., U.S.A., Director.

1901. Kauder, Dr. E. c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.

1903. Kauffman, Milton H., American Smelting and Refining Co., Durango, Colo., U.S.A., Chemist.

1910. Kaufmann, George von, Solotwina, Ost-Galizien, Austria, and (Journals) Christ's College, Cambridge, Director (Austrian Petroleum Co.).

1892. Kaufmann, Dr. Herbert M., c/o Mutual Chemical Co., Jersey City, N.J., U.S.A., Chemist.

1904. Kaus, Dr. Emil, c/o Roessler and Hasslacher Chemical Co., Perth Amboy, N.J., U.S.A., Chemist.

1885. Kawakita, Prof. Michitada, Imperial Engineering College, Tokio, Japan, Professor of Applied Chemistry.

1912. Kay, Jas. H., Hazle Bank, Bolton Road, Ramsbottom, Lancashire, Soap Manufacturer.

O.M. Kay, Wm. E., 349, The Cliff, Broughton Park, Manchester, Printworks Chemist.
1910. Kaye, Henry R., c/o Cuming, Smith, and Co., Port Melbourne, Vic., Australia, Analytical Chemist,
1904. Kaye, Thos., 26, Rose Crescent, Perth, Scotland. Analytical Chemist.
1884. Keane, Dr. Chas. A., Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., Principal.
O.M. Kearns, H. W., Baxenden, near Accrington, Dyer.
1897. Kearns, Jno. S., Cowpe Mills, Waterfoot, near Manchester, Chemist and Dyer.
1894. Kebler, Lyman F., 1322, Park Road, Washington, D.C., U.S.A., Chief of Drug Laboratory, Department of Agriculture.
1908. Keeble, A. J., Wereham Hall, Stoke Ferry, Norfolk, Land Owner.
1910. Keeler, Warren I., 214, Main Street, New Britain, Conn., U.S.A., Analytical Chemist.
1911. Keenan, Thomas J., 117, East 24th Street, New York City, U.S.A., Paper Chemist.
1910. Keillor, John, Hamilton Gas Light Co., Hamilton, Canada, Gas Engineer.
1908. Keith, Jas. W., c/o C. Tennant and Co., Ltd., Carnoustie, Forfarshire, Analytical Chemist.
1907. Keller, Dr. Edward, P.O. Box 363, Perth Amboy, N.J., U.S.A., Chemist and Metallurgist.
1905. Keller, Robt. J., 89, Barclay Street, New York City, U.S.A., Dyestuff and Chemical Merchant.
1885. Kellner, Dr. Wm., 135, Victoria Road, Old Charlton, S.E., Chemist to War Department.
1908. Kellogg, H. W., c/o National Electrolytic Co., Niagara Falls, N.Y., U.S.A., General Manager.
1910. Kemmerich, Dr. Wm. E., Farbenfabr. vorm. F. Bayer und Co., Leverkusen, bei Cöln, Germany, Chemist.
1907. Kendall, G. F., Chemical Works, Stratford-on-Avon, Chemical Manufacturer.
1912. Kennedy, Carl D., Chemist.
1912. Kent, Raymond W., East Palistine, Ohio, U.S.A., Chemist.
1903. Kenyon, Percy S., Park House, Cheadle Hulme, Cheshire, Drysalter.
1889. Kenyon, Thos., The Shrubbery, Hilton Park, Prestwich, near Manchester, Manufacturing Chemist.
1899. Kern, Walter P., 266, Paulison Avenue, and (Journals) c/o General Chemical Co., Dundee Works, Passaic, N.J., U.S.A., Chemist.
1906. Kerr, Charles H., c/o Pittsburg Plate Glass Co., Creighton, Pa., U.S.A., Ceramic Research Chemist.
1912. Kerr, R. Vaughan, c/o Señor D. Luis Moscardo. Alfredo Calderon 4, Valencia, Spain, Technical Chemist.
1890. Kerr, Saml. T., 516, North Delaware Avenue, Philadelphia, Pa., U.S.A., Salt Manufacturer.
1897. Kerr, Wm. M., 712, La Fayette Building, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1896. Kershaw, Jno. B. C., West Lancashire Laboratory, Waterloo, Liverpool, Analytical Chemist.
1909. Kesava-Menon, A., Chittur-Palghat, South Malabar, Madras, India, Chemist.
1902. Kessler, Henry W., 720, Electric Building, Cleveland, Ohio, U.S.A., Manufacturing Chemist.
1893. Kestner, Paul, 7, Rue de Toul, Lille. France, Chemist.
1900. Kewley, Jas., c/o Anglo-Egyptian Oilfields, Ltd., Suez, Refinery Manager.
1890. Keys, W. H., Hall End Works, West Bromwich, Oil and Chemical Manufacturer.
1913. Kilby, Jos. N., 11, Westfield Grove, Wakefield, Assistant Manager (Steel Plant).
1900. Kilgore, Benj. W., Raleigh, N.C., U.S.A., Chemist.
1901. Kilmer, Fred. B., c/o Messrs. Johnson and Johnson, New Brunswick, N.J., U.S.A., Chemical Manufacturer.
O.M. Kinch, E., Royal Agricultural College, Cirencester, Professor of Chemistry.
1912. Kind, Georg E., 33, King Street, Covent Garden, London, W.C., Bookseller and Publisher.
O.M. King, A. J., Elleray, Windermere, Bleacher and Finisher.
1907. King, C. A., c/o The Farnley Iron Co., Farnley, near Leeds, Technical Chemist.
1913. King, Edward W., New Liverpool Rubber Works, Walton, Liverpool, Analytical Chemist.
1905. King, Frank E., 75, Gracechurch Street, London, E.C., Analytical Chemist.
1911. King, Harold, 24, The Brent, Dartford, Kent, Chemist.
O.M. King, J. Falconer, 43, Stirling Road, Edinburgh, Consulting Chemist.
1910. King, John, Summerville Gardens, Latchford, Warrington, Lancashire, Works Manager.
1913. King, Dr. Robert C., V.O., Fifth Line 34, St. Petersburg, Russia, Chemist.
1895. King, Sidney J., Brean, Upton Road, Bexley Heath, Kent, Analytical Chemist.
O.M. King, Walter R., 16, Mincing Lane, London, E.C.; and (Journals) Torville, The Cliffs, Southend-on-Sea, Chemical Manufacturer.
1905. King, Warren C., 72, Front Street, New York City, U.S.A., President, Independent Chemical Co.
1896. Kingdon, Holman, c/o Joseph Crosfield and Sons, Warrington, Technical Chemist.
1908. Kingsbury, Percy C., German-American Stoneware Works, 50, Church Street, New York City, U.S.A., Chief Civil Engineer.
1883. Kingsford, T. P., Oswego, N.Y., U.S.A., Starch Manufacturer.
O.M. Kingzett, C. T., "Maplin," Frinton on Sea, Essex, and (Journals) Sanitas Co., Ltd., Locksley Street, Limehouse, E., Technical Chemist.
1906. Kinnersley, H. W., Branscombe, Merry Hill Road, Bushey, Herts, Chemist and Manufacturer.
1897. Kipping, Dr. F. Stanley, F.R.S., University College, Nottingham, Prof. of Chemistry.
1908. Kirkhope, T. Bertram, Sandbank, Gwithian, Hayle, Cornwall, Explosives Works Chemist.
1905. Kirkland, John, 105, Holmdene Avenue, Herne Hill, S.E., Technical Instructor.
1900. Kirkpatrick, Prof. Stafford F., 84, Gore Street, Kingston, Ont., Canada, Professor of Metallurgy.
1913. Kirsebom, Gustave, Braden Copper Co., Molino, Rancagua, Chile, Metallurgical Engineer.
1911. Kirstein, H. C., 7, Gracechurch Street, London, E.C., Consulting Engineer.
1902. Kitchen, Wm. J., Port Melbourne North, Vic., Australia, Soap and Candle Manufacturer.
1883. Kitto, B., 26, Lancaster Road, Finsbury Park, London, N., Analytical Chemist.
1900. Kittredge, H. G., c/o The Kay and Ess Co., Dayton, Ohio, U.S.A., Chemist.
1908. Klaber, Wm., c/o Castle Kid Co., Camden, N.J., U.S.A., Chemist.
1900. Kleber, Dr. Clemens, Clifton Chemical Laboratory, Passaic, N.J., U.S.A., Director.
1911. Klein, C. A., 4, Brimsdown Avenue, Enfield Highway, Middlesex, Works Chemist.
1908. Klein, Dr. Friedrich, 762, Melrose Avenue, New York City, U.S.A., Chemist.
1909. Klemm, Wilfred E., 25, Marmion Road, Liverpool, Chemist.
1908. Klien, Dr. J. L., 7, King Street, Cheapside, London, E.C., Works Manager.
1903. Kline, Clarence M., 429, Arch Street, Philadelphia, Pa., U.S.A., Wholesale Druggist.
1889. Klipstein, A., 644—654, Greenwich Street, New York City, U.S.A., Chemical Manufacturer.
1902. Klipstein, Ernest C., 93, Prospect Street, East Orange, N.J., U.S.A., Chemical Merchant.
1913. Klotz, W. C., Canadian Ammonia Co., Ltd., Toronto, Canada, Chemist.
1891. Knaggs, Alfred B. 37, Mannville Terrace, Bradford, Technical Chemist in Dyeworks.
1911. Knapp, Arthur W., c/o Cadbury Bros., Ltd., Bourneville, nr. Birmingham, Analytical Chemist.
1911. Knapp, Harry P., Chemical Manufacturer.
1892. Knecht, Dr. E., Beech Mount, Marple, Cheshire, Professor of Tinctorial Chemistry.
1904. Kniffen, Frederick, 823, North Franklin Street, Wilmington, Del., U.S.A., Chemist.

1887. Knight, A. H., 51, Highfield Street, Liverpool, Assayer.

1903. Knight, Harley F., 14, Old Queen Street, Westminster, S.W., Analyst.

1884. Knight, Henry, Stanley House, 73, Anfield Road, Liverpool, Colour and Varnish Manufacturer.

O.M. Knight, J. Baillie, Royal Primrose Soapworks, Silvertown, London, E., Soap Manufacturer.

1887. Knights, J. West, 67, Tenison Road, Cambridge, Analytical Chemist.

1885. Knipler, F., "Strathberg," Greensborough, near Melbourne, Victoria, Starch Manufacturer.

1907. Knoedler, E. L., c/o Welsbach Co., Gloucester City, N.J., U.S.A., Factory Foreman.

1910. Knott, E. Anthony F., The Priestman Collieries, Ltd., Ottovale Coke Works, Blaydon-on-Tyne, Works Chemist.

1911. Knowland, Daniel P., 89, Barclay Street, New York City, U.S.A., Chemist.

1904. Knowles, W. R., The Hollies, Wood Green, Wednesbury, Chemical Works Manager.

1886. Knox, E. W., Colonial Sugar Refining Co., Sydney, N.S.W.; and (subs.) c/o Parbury, Henty, and Co., 20, Eastcheap, London, E.C., Sugar Manufacturer and Refiner.

1906. Knudsen, Kristian Hv., Tofte Cellulosefabrik, Norway, Chemist.

1905. Koch, Dr. Geo. W., 905, Willoughby Avenue, Brooklyn, N.Y., U.S.A., Chemist.

1904. Koch, J. A., Bluff and Pride Streets, Pittsburg, Pa., U.S.A., Chemist.

1911. Kochs, A. Victor, 301, Glossop Road, Sheffield, Gas Engineer.

1904. Koebig, Dr. J., Suite 1026, Union Oil Building, Los Angeles, Cal., U.S.A., Consulting Chemical Engineer.

1909. Kockkoek, Patrick R., Works Chemist.

1911. Koelle, Dr. G., Metallbank und Metallurgische Gesellschaft, Bockenheimer Anlage 45, Frankfurt a/M., Germany, Chemist.

1884. Kohn, Dr. Charles A. *See* Keane, Dr. Chas. A.

1902. Kohnstamm, Lothair S., 87, Park Place, New York City, U.S.A., Chemist.

1913. Komuro, T., c/o A. Rawle, Lancaster House, Child's Hill, N.W., Chemical Engineer.

1913. Kondo, K., 136, Yoyogi, Tokyo, Japan, Chemical Engineer.

O.M. Kraftmeier, E., Bank Buildings, St. James's Street, London, S.W., Explosives Manufacturer.

1906. Krais, Dr. Paul, Lustnauer Allee, Tuebingen, Germany, Chemist.

1894. Krause, Dr. Albert H., 1444, West 98th Street, Cleveland, Ohio, U.S.A., Chemist (Grasselli Chemical Co.).

O.M. Krause, Prof. Dr. G., Cöthen (Anhalt), Germany, Chemist.

1898. Krebs, H. J., 806, Franklin Street, Wilmington, Del., U.S.A., Manufacturing Chemist.

1908. Kress, Otto, 438, West 116th Street, New York City, U.S.A., Teacher of Science.

1900. Kunheim, Dr. Erich, Niederschöneweide, near Berlin, Germany, Chemist.

1904. Kunz, Dr. George F., c/o Tiffany and Co., 409, 5th Avenue, New York City, U.S.A., Gem Expert.

1905. Kurt, Franklin T., 553, Boylston Street, Boston, Mass., U.S.A., Professor of Chemistry, B.Y.M.C.A.

1907. Kutsch, Dr. Wm. A., c/o Corn Products Manufacturing Co., Pekin, Ill., U.S.A., Chemist.

1900. Kuttroff, Fred., 128, Duane Street, New York City, U.S.A., Merchant.

1909. Kwoh, See Kwain, Municipal Technical College, Mukden, Manchuria, China, Chemical Engineer.

O.M. Kynaston, J. W., 3, Oak Terrace, Beech Street, Liverpool, Chemical Engineer.

1907. Kynaston, Wm. C. R., 9, Harland Road, Higher Tranmere, Birkenhead, Analyst.

L

1906. Lacell, Harold G., Ardoch, Nether Street, Finchley, N., Chemist.

1890. Lacey, E. C., St. Julian's Lodge, St. Julian's Farm Road, West Norwood, Manufacturing Chemist.

1903. Lachman, Dr. Arthur, 3037, Wheeler Street, Berkeley, Cal., U.S.A., Chemical Engineer.

1913. Laib, Walter, Rittman, Wayne Co., Ohio, U.S.A., Chemist (Ohio Salt Co.).

O.M. Laidler, C. P., 20, Noble Terrace, Gateshead-on-Tyne, Analytical Chemist.

O.M. Lake, G., jun., Lee Mount, Glossop, Derbyshire, Analytical Chemist.

1907. Lake, Henry B., Lavorrick, Mevagissey, Cornwall, Chemical Engineer.

1900. Lamar, Wm. R., Lamar Chemical Works, 8—14 Johnson Street, Newark, N.J., U.S.A., President.

1898. Lamb, Morris Chas., Leathersellers' Technical College, 176, Tower Bridge Road, London, S.E., Chemist.

1912. Lampitt, Leslie H., La Meunerie Bruxelloise, Haren Nord, Brussels, Belgium, Research Chemist.

1912. Lancaster, Harry C., 135, Ladbroke Road, Kensington, W., Managing Director.

1907. Lancaster, Harry M., Laboratory, Provincial Board of Health, 5, Queen's Park, Toronto, Canada, Chemist.

1910. Landrum, R. D., 1139, Belview Avenue, Canton, Ohio, U.S.A., Chemical Engineer.

1904. Lane, C. Cyril P., c/o The Avon India-Rubber Co., Melksham, Wilts., Chemist.

1910. Lane, J. Henry, 3, Arbour Square, Stepney, London, E., Chemist.

1903. Lane, Nathaniel J., U.S. Laboratory, 641, Washington Street, New York City, U.S.A., Chemist.

1893. Lang, Dr. Wm. R., University of Toronto, Canada, Professor of Chemistry.

O.M. Langdon, Dr. M. J., The Chemists' Club, 52, East 41st Street, New York City, U.S.A., Analytical Chemist.

1892. Langer, Dr. Carl, Ynyspenllwch, Clydach, R.S.O., Glamorganshire, Analytical Chemist.

1897. Langmuir, Arthur C., c/o Marx and Rawolle, 9, Van Brunt Street, Brooklyn, N.Y., U.S.A., Factory Manager.

1902. Langmuir, F. Leighton, 350, Bloor Street West, Toronto, Canada, Chemist.

1898. Langstaff, Wm., 39, Orchard Street, Elizabeth, N.J., U.S.A., Chemist.

1900. Lant, Herbert, "Ivy Bank," Wath-on-Dearne, near Rotherham, Yorks, Chemist and Manager.

1909. Lantsberry, Fred. C. A. H., Birmingham Small Arms Co., and (Journal) 63, Walford Road, Sparkbrook, Birmingham, Metallurgical Chemist.

1906. Lantz, Alfred, 139, Rue La Fayette, Paris, France, Colour Works Manager.

1903. Larter, Alfred T., 86, Inderwick Road, Stroud Green, N., Chemist.

1904. Lasher, F. G., 251, Bush Street, Brooklyn, N.Y., U.S.A., Chemist.

1884. Latham, Baldwin, Parliament Mansions, Victoria Street, Westminster, S.W., Civil Engineer.

1889. Latham, J. J., Mill House, Bold, Widnes, Chemical Works Manager.

1907. Lathwood, Arthur, c/o Borax Consolidated, Ltd., 16, Eastcheap, London, E.C., and (Journals) 23, Clarence Road, Wood Green, N., Chemist.

1909. Law, Douglas J., Trent Bridge Leather Works, Nottingham, Chemist.

1913. Law, John A., c/o Barry, Ostlere, and Shepherd, Ltd., Forth Works, Kirkcaldy, Scotland, Linoleum Works Director.

1907. La Wall, Chas. H. 39, South 10th Street, Philadelphia, Pa., U.S.A., Analytical Chemist.

O.M. Lawrence, Jas., Box 737, Joplin, Mo., U.S.A., Explosives Manufacturer.

1911. Lawrence, Wm. A., Laboratory, 11, Vandewater Street, New York City, U.S.A., Director.

1904. Lawson, Jos. H. S., Rodney Street Works, Oldham Road, Manchester, Salesman.

1900. Lawson, Wm. L., c/o Great Western Sugar Co., Sterling, Colo., U.S.A., Chemist.

1894. Lawson-Johnston, G., (Journals) 29, Portman Square, W., and 1, King's Arms Yard, London, E.C., Chairman of Bovril, Ltd.

1894. Lawson-Johnston, W. E., c/o Bovril, Ltd., 152, Old Street, London, E.C., Director.

1907. Leach, Dr. F. P., Briarswood, Chester Road, Erdington, Birmingham, Research Chemist.

1908. Leake, Percy C., Deanbank Terrace, Ferryhill Village, Co. Durham, Tar Works Manager.

1898 Lean, Geo., 15, Park Terrace, Glasgow, Chemist.

1897. Leathart, Thos. H., Lead Works, Newcastle-on-Tyne, Lead Manufacturer.

O.M. Leather, Dr. J. Walter, Agricultural Research Institute, Pusa, Behar and Orissa, India, Government Chemist.

1913. Lebach, Dr. Hans, c/o The Bakelite Co., Ltd., Orb Works, Cowley, near Uxbridge, Middlesex, Chief Chemist.

1893. Le Boutillier, Clement, c/o Taylor Iron and Steel Co., High Bridge, N.J., U.S.A., Chemist.

1907. Lecco, Prof. Marco T., Vasina 15, Belgrade, Servia, Professor of Chemistry.

1904. Le Chatelier, Prof. H., 75, Rue Notre Dame des Champs, Paris, France, Professor (l'Ecole des Mines).

1896. Lecomber, W. G., Cambridge Works, Knott Mill, Manchester, Engineer.

1896. Lederle, Dr. E. J., 39, West 38th Street, New York City, U.S.A. Chemist.

1892. Ledoff, Prof. A., Technological Institute, Kharkoff, Russia, Professor of Chemistry.

1895. Ledoux, Dr. Albert R., 99, John Street, New York City, U.S.A., Chemist.

1903. Ledoux, Aug. D., 15, William Street, New York City, U.S.A., Importer of Pyrites.

1905. Lee, Ashton, Lawrence, Mass., U.S.A., Manufacturing Chemist.

1905. Lee, Frank W., Lawrence, Mass., U.S.A., Manufacturing Chemist.

1905. Lee, John C., Mountford Street, Brookline, Mass., U.S.A., Assistant Engineer (American Telegraph and Telephone Co.).

1898. Lee, Jno. L., Woodfield, Lytham, Lancashire, Dyer and Bleacher.

1911. Lee, Joseph, c/o Mr. Gill, 280, Alma Street, Rockhampton, Queensland, Works Chemist.

1885. Lee, S. Wright, 6-10, Whitechapel, Liverpool, Wholesale Druggist.

1906. Lee, William, 28, Sherard Gardens, Eltham, Kent, Works Chemist.

1912. Lees, Arnold, 14, Priory Street, York, Analytical Chemist.

1901. Leffler, Rudolf L., c/o Thos. Firth and Sons, Ltd., Norfolk Works, Sheffield, Metallurgical Chemist.

1907. Lehmann, Dr. Adolf, University of Alberta, Strathcona, Alberta, Canada, Professor of Chemistry.

1888. Leigh, Cecil, Birmingham Metal and Munition Co., Adderley Park Rolling Mills, Birmingham, Technical Chemist.

1906. Leigh, Edw. Collier, c/o Companhia de Gaz, Parà, North Brazil, Gas Works Manager.

1902. Leighton, A. E., Commonwealth Cordite Factory, Maribyrnong, Victoria, Analytical Chemist.

1894. Leitch, Jno. W., Milnsbridge Chemical Works, near Huddersfield, Aniline Dye Manufacturer.

1904. Le Maistre, Fred J., Room 727, Du Pont Building, Wilmington, Del., U.S.A., Research Chemist.

1898. Leman, Wm. T., P.O. Box 747, Chicago, Ill., U.S.A., Oil and Asphalt Agent.

1908. Lemeland, Dr. P., 8, Rue Alfred de Vigny, Paris, France, Chemist.

1883. Lennard, F., Ifford Manor House, near Lewes, Sussex, Chemical Manufacturer.

1884. Leonard, Wm. J., 1, Lindfield Gardens, Hampstead, N.W., Naphtha Distiller.

1888. Lequin, E., Directeur Général des Usines de Produits Chimiques de la Société de St. Gobain, 1, Place des Saussaies, Paris (VIII^e.), France.

1904. Lesley, R. W., 604, Pennsylvania Building, Philadelphia, Pa., U.S.A., Cement Manufacturer.

1907. Leslie, Dr. Fred. A., College of Pharmacy, 115, West 68th Street, New York City, U.S.A., Chemist.

1894. Leslie, Hugh M., 10, St. Andrew's Drive, Pollokshields, Glasgow, W., Chemical Engineer.

1904. Lessing, Dr. Rudolf, Southampton House, 317, High Holborn, London, W.C., Consulting Chemist.

1912. Lessner, C. B., Carril, Spain, Metallurgical Chemist.

1892. Lester, J. H., Grange Drive, Monton Green, Eccles, Lancs, Analytical Chemist.

1899. Le Sueur, Dr. Henry R., Chemical Laboratory, St. Thomas' Hospital, London, S.E., Demonstrator.

1891. Lever, Sir Wm. H., Bart., Thornton House, Thornton Hough, Cheshire, Soap Manufacturer.

1909. Lever, W. Hulme, Heathfield, Bebington, Cheshire, Soap Manufacturer.

1901. Levett, Walter, Holmlands, Stanford-le-Hope; and (Journals) Mines Safety Explosives Co., Stanford-le-Hope, Essex, Factory Manager.

1903. Levi, Dr. Louis E., 781, Sherman Boulevard, Milwaukee, Wis., U.S.A., Chemist.

1912. Levin, Isaac H., 796, Frelinghuysen Avenue, Newark, N.J., U.S.A., Chemist.

1906. Levinstein, Edgar, 74, India Street, Boston, Mass., U.S.A., Chemical Manufacturer.

1901. Levinstein, Dr. Herbert, c/o Levinstein, Ltd., Blackley, near Manchester, Chemist.

O.M. Levinstein, Ivan, Hawkesmoor, Fallowfield, Manchester, Colour Manufacturer.

1903. Levy, Arthur G., 1927, Madison Avenue, New York City, U.S.A., Chemist.

1909. Levy, Louis S., 80, Maiden Lane, New York City, U.S.A., Editor, "American Perfumer."

1901. Levy-Mond, Dr. Albert. *See* Mond, Dr. Albert L.

1887. Lewes, Prof. Vivian B., Royal Naval College, Greenwich, S.E., Professor of Chemistry.

1898. Lewin, H. James, Royal Clarence Yard, Gosport, Hants, Analytical Chemist.

1914. Lewis, C. Preston, 223, Brixton Hill, London, S.W., Technical Chemist.

1896. Lewis, Daniel C., c/o Millville Manufacturing Co., Millville, N.J., U.S.A., Dye Works Chemist.

1904. Lewis, Edw. W., c/o J. G. Ingram and Sons, London India Rubber Works, Hackney Wick, N.E., Chemist.

1900. Lewis, Ernest A., 310, Dudley Road, Birmingham, Chemist and Metallurgist.

1905. Lewis, F. W., Aetna Powder Co., 143, Dearborn Street, Chicago, Ill., U.S.A., Secretary.

1900. Lewis, John, 76, Underhill Road, Lordship Lane, S.E., Cashier (Paint Works).

1909. Lewis, Reginald J., Govt. Explosives Office, 423, Flinders Lane, Melbourne, Australia, Chemist.

1900. Lewis, Dr. S. Judd, The Laboratories, Staple Inn Buildings, High Holborn, London, W.C., Analytical Chemist.

1914. Lewis, Prof. W. C. McC., Muspratt Laboratory, The University, Liverpool, Professor of Physical Chemistry.

1913. Lewkowitsch, Mrs. K. J., The Lewkowitsch Laboratories, 71, Priory Road, West Hampstead, N.W.

1907. Leyson, Lewis T., c/o Standard Bank of South Africa, Johannesburg, Transvaal, Analytical Chemist.

1901. Lichtenstein, Alf. F., c/o Geisenheimer and Co., P.O. Box 994, New York City, U.S.A., Chemist.

1913. Lichtenstein, L. M., Royal Albert and Victoria Docks Chemical Works, Silvertown, London, E., Manufacturing Chemist.

1904. Lichtenthaeler, Robt. A., Rhode Island Agricultural Experiment Station, P.O. Box 112, Kingston, R.I., U.S.A., Chemist.

1913. Lidholm, J. H., c/o Alby United Carbide Factories, Ltd., 308, Winchester House, Old Broad Street, London, E.C., Chemical Engineer.

1904. Lieber, Dr. Hugo, 25, Madison Avenue, New York City, U.S.A., Chemist.

O.M. Liebmann, Dr. A., The Whim, Weybridge, Surrey, Consulting Chemist.

1913. Liebreich, Dr. Erik, 30, Kronprinzen Ufer, Berlin Germany, Chemist.
O.M. Lighttoot, T. E., Fernleigh, Accrington, Calico Printer's Chemist.
1905. Liley, Thos. A., 46, Westover Road, Bramley, Leeds, Chemist.
1898. Lilly, Josiah K., c/o Eli Lilly and Co., Indianapolis, Ind., U.S.A., Manufacturing Pharmacist.
1904. Lindemann, Ottocar, 53, Victoria Street, Westminster, S.W., Managing Director (Korting Bros., Ltd.)
1908. Lindfield, James H., c/o Messrs. Martineau, King Edward Street, Whitechapel, E., Technical Chemist.
1897. Lindsay, Robt., Transvaal G.M. Estates, Pilgrim's Rest, Lydenburg, Transvaal, Chemist.
1911. Line, Chas. A., 39, Beaufort Road, Edgbaston, Birmingham, Technologist.
1890. Ling, Arthur R., Laboratory, 74, Great Tower Street, London, E.C., Consulting Chemist.
1905. Lips, Dr. Carl H., 99, Hart Street, Brooklyn, N.Y., U.S.A., Chemist.
1896. Lishman, Geo. P., Lambton Coke Works, Fence Houses, Co. Durham, Colliery Chemist.
1905. Little, Arthur D., 93, Broad Street, Boston, Mass., U.S.A., Consulting Chemist.
O.M. Littlejohn, Jas., c/o Littlejohn and Whitby, P.O. Box 849, Johannesburg, Transvaal, Analytical Chemist.
1911. Liu, Hamilton C., Dept. of Public Works, Board of Interior Affairs, Pekin, China, viâ Siberia, Chemist.
1904. Livermore, W. D., Washington Mill, Lawrence, Mass., U.S.A., Chemist.
1886. Liversedge, A. J., 63, Northampton Road, Croydon, Mechanical Engineer.
1914. Liversedge, John A., May Morn Mills, Mangaron, near Wellington, New Zealand, Assistant Lead Mill Manager.
1906. Liversedge, S. G., Elmhurst, Chalkwell Park Drive, Leigh on Sea, Essex, Analytical Chemist.
1904. Liverseege, J. F., Analytical Dept., 44, Broad Street, Birmingham, City Analyst.
O.M. Liversidge, Prof. A., F.R.S., Field Head, Coombe Warren, Kingston, Surrey, Professor of Chemistry.
1907. Liversidge, Bernard, Cliffhurst, Clifton Crescent North, Rotherham, Yorks, Analytical Chemist.
1883. Livingston, W. J., 30, Fountayne Road, Stoke Newington Common, London, N., Analytical Chemist.
1903. Llewellyn, Ivor P., 149, Moorland Road, Stockport, Chemist.
1907. Llewellyn, W. B., 61, Belgrave Road, New Moston, Manchester, Chemist.
1909. Lloyd, Edward, 27, Broomgrove Road, Sheffield, Chemical Engineer.
1913. Lloyd, Prof. Francis E., Dept. of Botany, McGill University, Montreal, Canada, Prof. of Botany.
1904. Lloyd, Leonard B., Broadford Tannery, Broadford, Victoria, Australia, Tanner.
1907. Lloyd, Dr. Lorenzo L., Technical College, Bradford, Yorks, Lecturer in Chemistry.
1908. Lloyd, Capt. M. B., 3, Neville Terrace, Onslow Gardens, London, S.W., Director of Curtis's and Harvey, Ltd.
1900. Lloyd, Thos. H., c/o Quibell Bros., Newark-on-Trent, Analyst.
1909. Lobley, A. G., Mill Bank, Trefriw, North Wales, Chemist.
1888. Lodge, Edw., 35, Scale Hill, Cowcliffe, Huddersfield, Teacher of Wool Dyeing.
1891. Loewenthal, Dr. R., Uhlandstrasse 39, Frankfurt a/M., Germany, Lecturer on Dyeing.
1907. Lomax, E. Lawson, Mowbreck, Farington, near Preston, Chemist.
1901. Long, Eugene J., c/o E. O'Callaghan and Son, City Tannery, Limerick, Ireland, Tanner.
1909. Long, George, Cudahy, Wis., U.S.A., Glue Maker.
1898. Longstaff, Dr. Jas. P., Chemical Department, The University, Edinburgh, Assistant.
1908. Longwell, Alex., 404, Lumsden Building, Toronto, Canada, Mining Engineer.
1890. Lord, F. J., Winmarleigh, Southborne, Bournemouth, Hants, Analytical Chemist.
1896. Lord, Jno. Lloyd, 23, Park View, Elton, Bury, Lancs, Chemist and Manager.
O.M. Lorenz, H., 7 and 8, Idol Lane, London, E.C., Chemical Merchant.
1904. Lorimer, John H., 280, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Textile Machinist and Merceriser.
1905. Loring, Lindsley, 40, Central Street, Boston, Mass., U.S.A., Vice-President (Cochrane Chemical Co.).
1909. Lorleberg, C., c/o R. W. Greeff and Co., Thames House, Queen Street Place, London, E.C., Chemical Merchant.
O.M. Lorrain, Jas. G., Staple Inn Buildings, Holborn, London, E.C., Chartered Patent Agent.
1904. Lossen, Dr. Clemens F., Boulevardul Independentei 8, Ploesti, Roumania, Chemist.
O.M. Lott, F. E., The Laboratory, Bridge Chambers, Burton-on-Trent, Consulting Brewing Chemist.
O.M. Louis, D. A., 123, Pall Mall, London, S.W., Metallurgist and Mining Engineer.
1894. Louis, Prof Henry, Armstrong College, Newcastle-on-Tyne, Professor of Mining.
O.M. Love, Dr. E. G., 124, East 15th Street, New York City, U.S.A., Analytical Chemist.
1899. Love, Wm., 28, Royal Exchange Square, Glasgow, Managing Director (Broxburn Oil Co., Ltd.).
1895. Lovejoy, Frank W., 22, Seneca Parkway, Rochester, N.Y., U.S.A., Chemical Engineer.
O.M. Lovibond, J. W., The Pleasaunce, Lake, near Salisbury, Tintometer Manufacturer.
O.M. Lovibond, T. W., West Jesmond House, Newcastle-on-Tyne, Brewer.
1913. Low, Frank S., c/o Cutler-Hammer Manufacturing Co., 144th Street and Southern Boulevard, New York City, U.S.A., Chemical Engineer.
1900. Low, Prof. Wilson H., Cudahy Packing Co., South Omaha, Neb., U.S.A., Chemist.
1911. Lowcock, J. Harold, Garstang, Kemerton Road, Beckenham, Kent, Chemist.
1913. Lowe, Austin, 41, Lavender Sweep, Battersea, S.W., Research Chemist.
1887. Lowe, Clement W., Thorneyholme, Knutsford, Cheshire, Manufacturing Chemist.
1905. Lowe, Houston, The Lowe Bros. Co., 452, East Third Street, Dayton, Ohio, U.S.A., Paint and Varnish Maker.
O.M. Lowe, W. F., 18, Hough Green, Chester, Analytical Chemist.
1885. Lowson, Dr. J. G. F., Snitterfield House, Stratford-on-Avon, Paper Maker.
1906. Lowson, Wm., The University, Leeds, Chemical Lecturer.
1895. Lucas, Alf., Laboratories, Public Works Ministry Gardens, Cairo, Egypt, Analyst.
1892. Lucas, Bernard R., Winnington Park, Northwich, Alkali Works Manager.
1914. Lucas, Wm. A., c/o Braden Copper Co., Rancagua, Chile, Chemist.
O.M. Luck, A. Courtenay, Laboratorio de Explosivos, Darsena Norte, Buenos Aires, Argentina Explosives Chemist.
1913. Lucy, Arthur J., c/o Turner, Morrison and Co., Calcutta, India, Consulting Engineer.
1900. Lummus, Walter E., 39, Bassett Street, Lynn, Mass. U.S.A., Manager.
1903. Lumsden, Alex. A., Forth Chemical Works, Bo'ness, Scotland, Technical Chemist.
1910. Lumsden, William W., 39, Caledonia Road, Saltcoats, Scotland.
1888. Lund, Jas., 142, Hawthorne Street, Malden, Mass., U.S.A., Ammonia Works Manager.
1888. Lundholm, Carl O., 220, Winchester House, Old Broad Street, London, E.C., Explosives Works Manager.
1913. Lunge, Ernest, 2, Plowden Buildings, Temple, London, E.C., Barrister-at-Law.
O.M. Lunge, Dr. G., Carmenstrasse 37, Zürich, Switzerland, Professor of Chemistry.

1885. Lupton, Sydney, 102, Park Street, Grosvenor Square, London, W.
1884. Lüthy, Otto, P.O. Box 63, Maywood, N.J., U.S.A., Analytical Chemist.
1913. Lycett, P. J., c/o The County Chemical Co., Ltd., Bradford Street, Birmingham, Chemist.
1903. Lye, Ernest B., Leagrave Hall, near Luton, Beds, Straw Plait Dyer and Bleacher.
1885. Lye, W. T., Leagrave Hall, near Luton, Beds, Straw Dyer.
1884. Lyle, James, Ardesco, West Silvertown, E., Sugar Refiner.
1885. Lyle, Jno., 21, Mincing Lane, London, E.C., Sugar Refiner.
1896. Lymn, Arthur H., Sanctuary House, Tothill Street, Westminster, S.W., Consulting Chemical and Gas Engineer.
1899. Lynn, R. Rankine, 7, Highburgh Terrace, Dowanhill, Glasgow, Chemical Engineer.
1902. Lyon, Edwd. H., 520, West 27th Street, New York City, U.S.A., Manufacturing Chemist.
O.M. Lyon, J. G., The Aire Tar Works, Knottingley, Yorks, Tar Distiller.
1906. Lyons, Robert H., c/o Canadian Explosives, Ltd., Vaudreuil Station, Quebec, Canada, Chemist.
O.M. Lytle, A. M., North of Ireland Chemical Co., Ltd., 34, Victoria Street, Belfast, Ireland, Chemical Manufacturer.

M

1908. Maas, Milton A., 92, William Street, New York City, U.S.A., Manufacturing Chemist.
1911. Mabbitt, Alan T., 3, Wallwood Road, Leytonstone, N.E., Analytical Chemist.
1887. Mabery, Prof. Chas. F., Case School of Applied Science, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1891. Macadam, Herbert E., Dalkeith, Glengall Road, Woodford Green, Essex, Manure Works Manager.
1894. Macadam, Stevenson, 55, York Place, Edinburgh, Analytical Chemist.
1912. McAfee, Dr. A. M., c/o The Gulf Refining Co., Bayonne, N.J., U.S.A., Chemist.
1894. McAlley, Robt., Bankside, Falkirk, Scotland, Paint Works Manager.
1892. Macara, Thos., jun., 20, Denton Road, Stroud Green, N., Chemist.
1912. McArly, T. P., Mount Lyell Mining and Railway Co., Queenstown, Tasmania, Chemist and Assayer.
1887. McArthur, James B., Price's Patent Candle Co., Limited, Belmont Works, Battersea, S.W., Chemist.
O.M. McArthur, J. S., 74, York Street, Glasgow, Consulting Chemist and Metallurgist.
1901. Macarthur, Jno. S., 15, St. John's Road, Pollokshields, Glasgow, Paint and Varnish Manufacturer.
1892. McArthur, Thos., 711, Tower Building, Water Street, Liverpool, Drysalter and Dyewood Extractor.
1912. Macaulay, J. W., Evermonde, Holmlands, Monkseaton, Northumberland, Metallurgical Chemist.
1911. McBride, K. R., Glens Falls, N.Y., U.S.A., Colour Chemist.
1898. MacCallum, D. A., 389, Central Chambers, 93, Hope Street, Glasgow, Chemist.
O.M. McCallum, J. M., Southdene, Paisley, Scotland, Soap Manufacturer.
1914. McCarthy, Robt. A., Bertram Street, Mortlake, Sydney, N.S.W., Australia, Assistant Chemist (Australian Gas Co.).
1905. McCaw, Lt.-Col. W. D., Library, Surgeon General's Office, Washington, D.C., U.S.A., Officer, Medical Department, U.S. Army.
1905. McCleary, Wm., 61, Station Road, Pendlebury, near Manchester, Finisher.
1910. McColl, A. L., 60, Addingham Road, Mossley Hill, Liverpool, Chemist.
1907. McConnan, Dr. Jas., 8, Crosby Road South, Waterloo, Liverpool, Chemist.
1903. McCourt, Cyril D., 45, Braxted Park, Streatham Common, S.W., Chemist.
1912. McCoy, James P. A., Research Division, Westinghouse Electric and Manufacturing Co., East Pittsburg, Pa., U.S.A., Analytical Chemist.
1913. McCrady, McH., 9, St. James' Street, Montreal, Canada, Chemist and Bacteriologist.
1897. McCrae, Dr. John, Government Laboratories, P.O. Box 1080, Johannesburg, Transvaal, Government Analyst.
1898. McCreath, Wm. D., Quantock Vale Cider Works, North Petherton, Bridgwater, Cider Manufacturer.
1911. McCulloch, Norman G., Rhodes Works, Rhodes, Manchester, Chemist and Calico Printer.
1903. McCully, R. E. J., 7, London Road, Northfleet, Kent, Analytical Chemist.
1910. Macdonald, Alexander, Brampton House, Camphill Avenue, Langside, Glasgow, Clerk.
1912. McDonald, Allan D., "Belgrano," Milngavie, near Glasgow, Manufacturing Chemist.
O.M. Macdonald, Andrew, 72, Great Clyde Street, Glasgow.
1912. McDonald, Donald, Cleeve House, Bexley Heath, Kent, Analytical Chemist.
1897. MacDonald, G. W., Whitefriars, Rochester, Kent, Chief Explosives Research Chemist (Curtis's and Harvey, Ltd.).
1910. Macdonald, J. L. A., 13, Howard Place, St. Andrews, Fife, Scotland.
O.M. Macdonald, J. W., 8, Prince of Wales Terrace, Kensington, W., Analytical Chemist.
1899. MacDonald, S. Fremont, c/o Ashtabula Hide and Leather Co., Ashtabula, Ohio, U.S.A., Tanner.
O.M. McDonald, T. McG., Walilabo Estate, St. Vincent, West Indies, Sugar Chemist.
1906. Macdougald, Geo. D., City Laboratory, 13, Shore Terrace, Dundee, City Analyst.
1895. McDougall, Isaac, jun., 68, Port Street, Manchester, Chemical Manufacturer.
1890. McDougall, J. T., Dunolly, Morden Road, Blackheath, S.E., Manufacturing Chemist.
1906. McDowall, Wm., 42, Herriet Street, Pollokshields, Glasgow, Analytical Chemist.
1889. MacEwan, Peter, 64, Southwood Lane, Highgate, N., Editor of "Chemist and Druggist."
1901. McEwen, Duncan C., c/o Chosen Gold Mines, Ltd., Kok-Kang-Kol Mine, Chung-An, Korea, Metallurgical Chemist.
1908. McEwen, Stewart R., c/o Chemical Laboratories, Ltd., 148, Van Horne Street, Toronto, Canada, Chemist.
1902. McFarland, Alan R., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Alkali Works Manager.
1910. McFarlane, John, 6, Gordon Terrace, Shettleston, Glasgow, Metallurgist.
O.M. Macfarlane, R. F., Tharsis Copper Works, East Moors, Cardiff, Works Manager.
1901. McFarlane, Walter, The Lodge, Brinscall, near Chorley, Printworks Manager.
1893. McGhie, T. Burns, c/o Bwana M'Kubwa Copper Mining Co., Bwana M'Kubwa, Northern Rhodesia, Metallurgist.
1904. McGill, Dr. A., 317, Queen Street, Ottawa, Canada, Analytical Chemist.
1899. MacGillivray, Wm. A., c/o Swansea Safety Fuse Co., Pipe House Wharf, Swansea, Analytical Chemist.
1887. McGlashan, John, P.O. Balapur Tolodi, Tehnil Brahmapuri, Dist. Chanda, India, Technical Chemist
1906. McGregor, Russell, 15, Frodingham Road, Scunthorpe, Lincolnshire, Analytical Chemist.
1896. McIlhiney, Dr. Parker C., 7, East 42nd Street, New York City, U.S.A., Chemist.
O.M. McIlwaine, Alf. W., Stoneferry, Hull, Oil Manufacturer.
O.M. MacIndoe, G. D., Ness Street, Invercargill, New Zealand. Public Analyst and Consulting Chemist.
1903. Macintire, Benj. Gould, 2226, West 17th Street, Wilmington, Del., U.S.A., Chemist.
1913. MacIntosh, George, 352, Elm Avenue, Westmount, Montreal, Canada, Glycerin Works Manager.

1909. McIntyre, George D., c/o Morris and Co., Nationa Stock Yards, Oklahoma City, Okla., U.S.A., Technical Chemist.
1914. MacIvor, R. W. Emerson, c/o Metals Recovery, Ltd., 47, Victoria Street, Westminster, S.W., Consulting Chemist.
1910. Mackay, Angus, Laboratory, Wellpark Brewery, Glasgow, Brewer's Chemist.
1911. Mackay, F., 3, Albany Terrace, Shettleston, Glasgow, Analytical Chemist.
1914. McKay, Gordon P., 13, Prince Arthur Avenue, Toronto, Canada, Chemist.
1912. McKechnie, Alex., Chad Hill Cottage, Edgbaston, Birmingham, Copper Smelter.
O.M. McKechnie, D. M., The Grange, Halewood, near Liverpool, Copper Extractor.
1904. McKechnie. R. D., Mount Gerald, Larbert, Stirlingshire, Chemical Engineer.
1887. McKellar, W. G., c/o United Alkali Co., Ltd., St. Rollox Works, Glasgow, Technical Chemist.
1895. McKenna, Dr. Chas. F., 50, Church Street, New York City, U.S.A., Chemist.
1899. McKenzie, Alex. H., 17, North Street, North Adams, Mass., U.S.A., Colour Mixer.
1909. Mackenzie, Kenneth G., c/o The Texas Co., Bayonne, N.J., U.S.A., Chemist.
1893. McKerrow, C. A., 8, Berners Street Mansions, London, W.; and (Journals) c/o Mitchells, Ashworth, and Co., 23-24, Old Bailey, London, E.C. Consulting Chemist.
1893. McKesson, John, 91, Fulton Street, New York City, U.S.A., Manufacturing Chemist.
1911. McKey, Arthur W., 216, Milk Street, Boston, Mass., U.S.A., Sales Agent.
1891. Mackey, W. McD., Victoria Chambers, Leeds, Analytical Chemist.
1912. McKillop, G. F., Oilworks, Broxburn, West Lothian, Scotland, Works Chemist.
1890. McKillop, Jno., 32, Aynho Road, Hammersmith, W., and (Jnls.) c/o W. Müller, 69A, Great Queen Street, Kingsway, W.C., Metallurgist.
1902. McKim, Wm., 37, Fairview Street, Yonkers, N.Y., U.S.A., Colour Maker.
1908. McLaren, Alex., 22, Moss Lane, Walton, Liverpool, Analytical Chemist.
1908. McLaren, Alex. W., 3, Hayfield Terrace, Langside, Glasgow, Analytical Chemist.
1914. McLaren, John, c/o Chiswick Polish Co., Ltd., Burlington Lane, Chiswick, W., Works Chemist.
1898. McLaurin, Robt., Homesteads, Cambusbarron, Stirling, Chemist.
1909. MacLaurin, Dr. Robert D., University of Saskatchewan, Saskatoon, Saskatchewan, Canada, Chemist.
1905. McLellan, Basil G., c/o Rowntree and Co., Ltd., The Cocoa Works, York, Technical Chemist.
1910. MacLellan, George A., 1, Montague Terrace, Glasgow, W., Rubber Manufacturer.
1910. MacLennan, Alex., Tannery, Ross, Herefordshire, Rubber Chemist.
1908. Macleod, Alex., Mount Pleasant, Old Kilpatrick, Dumbartonshire, Analytical Chemist.
1892. McLeod, Jas., Gas Works, Greenock, Manager.
1912. McMaster, Prof. Le Roy, Washington University, St. Louis, Mo., U.S.A., Assoc. Prof. of Chemistry.
1904. McMullen, Alan, Saint James' Gate, Dublin, Ireland, Brewer.
1889. McMurtrie, J.M., 212, West Regent Street, Glasgow, Brass Founder.
1895. McMurtry, G. C., Templemore, Richmond, Nelson, New Zealand, Manager.
O.M. Macnab, W., 10, Cromwell Crescent, London, S.W., Analytical Chemist.
1907. McNaughton, Wm. G., Port Edwards, Wis., U.S.A., Chemist.
1908. McQueen, James, jun., Phœnix Chemical Works, Pollokshaws, Glasgow, Chemical Manufacturer.
1912. McRae, J. A., 184, University Avenue, Kingston, Ont., Canada, Research Chemist.
1909. McWhirter, James, c/o Wm. Beardmore and Co., Laboratory, Parkhead Forge, Glasgow, Metallurgical Chemist.
1910. Madge, Norman, c/o Continental Rubber Co. of New York, 11, Vandewater Street, New York City, U.S.A., Chemist.
1895. Magnus, Isidor, 52, Leadenhall Street, London, E.C., Chemical Merchant.
1901. Magruder, Egbert W., Department of Agriculture, Richmond, Va., U.S.A., Chemist.
1912. Main, Hugh, Almondale, Buckingham Road, South Woodford, N.E., Analytical Chemist.
1998. Main, Wm., Piermont, N.Y., U.S.A., Chemist.
1904. Mair, William, 37, Morningside Drive, Edinburgh, Chemist.
1905. Major, Ernest, "Scafield," Day Street, Drummoyne, Sydney, N.S.W., Manufacturing Chemist.
O.M. Major, J. Lewis, Welton Garth, Brough, East Yorks, Tar Distiller and Chemical Manufacturer.
1910. Male, C. E., Brookland House, Cottenham, Cambs, Chemist.
1886. Mallinckrodt, Edw., Library, Mallinckrodt Chemical Works, St. Louis, Mo., U.S.A., Manufacturing Chemist.
1912. Manley, Chas. E., 8, Wilmington Gardens, Barking, Essex, Paint and Colour Works Manager.
1893. Mann, Harold H., Agricultural College, Poona, Bombay, India, Research Chemist.
1899. Mann, Jas. S., 19, Stopford Road, Upton Manor, Essex, Analyst.
1891. Mann, John C., 33, Nicholls Street, West Bromwich. Staffs, Chemist.
1903. Mannhardt, Hans, 1104, Oakdale Avenue, Chicago, Ill., U.S.A., Chemical Engineer.
O.M. Mannington, H. T., Marshlea, Beaconsfield Road, Farnworth, Widnes.
1909. Manns, Dr. J., c/o C. W. Schmidt, Varnish Works, Stratford, E., Chemist.
1892. Mansbridge, Wm., 4, Norwich Road, Wavertree, Liverpool, Chemist.
1904. Marckworth, O. S., Ohio Testing Laboratory, 426, Chamber of Commerce, Columbus, Ohio, U.S.A., Director.
1883. Markel, Dr. K. E., 20, Queen's Gate Terrace, South Kensington, S.W., Technical Chemist.
1905. Marland, Percy, c/o Brotherton and Co., Ltd., Provan Chemical Works, Millerston: and (Journal) 155, Hyndland Road, Glasgow, Technical Chemist.
1905. Marlatt, Wilbur T., Oakville, Ont., Canada, Leather Manufacturer.
1912. Marly, Dr. Simon M., 34, Arbour Street, Southport, Analytical Chemist.
1914. Marples, Morris E., The River Plate Fresh Meat Co., Ltd., Campana, F.C.C.A., Argentina, Chief Chemist.
1904. Marris, H. C., 68, Schlüsselburg Prospect, St. Petersburg, Russia, Analytical Chemist.
1901. Marsden, Dr. Fred., Technical Institute, Madura, South India, Chemist.
1906. Marsden, Oliver, Manor Road Mill, Victoria Road, Leeds, Cashier.
O.M. Marsh, J. T., Ammonia Soda Works, Fleetwood, Lancashire, Chemist.
1883. Marsh, W., Union Alkali Co., Soho Works, Ancoats, Manchester, Chemical Manufacturer.
1895. Marshall, Arthur, Waverley Cottage, Naini Tal, India, Chief Chemical Examiner.
1895. Marshall, Francis G., 56, Bewick Road, Gateshead, Technical Chemist.
1908. Marshall, John, Cudbear Street, Hunslet, Leeds, Dyeware Manufacturer.
1913. Marshall, Philip W., c/o The Fred. Crane Chemical Co., Armoury Close, Bordesley Green, Birmingham, Lacquer Manufacturer (retired).
1883. Marshall, Wm., Laboratory, Ladybrook Road, Cheadle Hulme, Cheshire, Dyer.
1884. Marshall, Wm., 9, Castello Avenue, Putney Park, S.W., Analytical Chemist.
1904. Marston, John P., 247, Atlantic Avenue, Boston, Mass., U.S.A., Merchant.
1894. Martin, Alex. M., Hillview, Twechar by Glasgow, Analytical Chemist.

1895. Martin, Chas. H., 50, Longmead Road, Claremont, Pendleton, Manchester, Oil and Soap Works Manager.

1913. Martin, Edwin J., c/o Jas. Martin and Sons, Luton, Beds, Bleacher and Dyer.

1911. Martin, Dr. G., 4. Bertram Road, Hendon, N.W., Science Teacher and Industrial Chemist.

1911. Martin, G. F. Wesley, Castle Park, Lancaster, Chemist.

O.M. Martin, N. H., Ravenswood, Low Fell, Gateshead-on-Tyne, Manufacturing Chemist.

1899. Martin, Wm. E., 111, Belle Vue Road, Durban, Natal, South Africa, Chemist.

1911. Martin, Wilmot S., 2, Coronation Terrace, Truro, Cornwall, Analyst and Assayer.

1887. Martineau, Sydney, Streatham Grove, Norwood, S.E., Sugar Chemist.

1907. Martius, Dr. C. A. von, Voss Strasse 12, Berlin, Germany, Dyestuff Manufacturer (retired).

1894. Martyn, T. Graham, Box 5, Maraisburg, Transvaal, South Africa, Metallurgist.

1909. Marx, Robert J., 133–139, Finsbury Pavement, London, E.C., Engineer.

1908. Mason, Douglas H. C., 448, Confederation Life Building, Toronto, Canada, Manufacturer.

1904. Mason, Dr. Edward D., 32, Vernon Road, Edgbaston, Birmingham, Scientific Apparatus Dealer.

1911. Mason, Francis A., c/o Murphy and Lonsdale, 4, Queen Square, Leeds, Analytical Chemist.

1906. Mason, Dr. Frederic S., 90, Beekman Street, New York City, U.S.A., Manufacturing Chemist.

1904. Mason, Glen F., c/o H. J. Heinz Co., Pittsburg, Pa., U.S.A., Chemist.

1887. Mason, J. Francis, Eynsham Hall, Witney, Oxon.

1910. Mason, James H., 180, Richmond Street West, Toronto, Canada, Metallurgist.

1906. Mason, M. Edgar, 268, Fox Street, Aurora, Ill., U.S.A., Consulting Chemist.

1906. Massa, Corradino, Castelguelfo Parmense, Parma, Italy, Sulphuric Acid and Fertiliser Manufacturer.

O.M. Masson, Prof. D. Orme, University of Melbourne, Victoria, Australia, Professor of Chemistry.

1908. Masson, R. Duncan, c/o Messrs. R. Silcock and Sons, Stanley Hall, Union Street, Liverpool, Analytical Chemist.

1902. Masujima, Prof. Bunjiro, c/o K. Takebe, 25, Gazenbocho, Azabuku, Tokyo, Japan, Prof. of Applied Chemistry.

1910. Matchet, Andrew S., 13, Bute Gardens, Muirend, Cathcart, Glasgow, Analytical Chemist.

1911. Mather, Hubert, Lonsdale Terrace, Whitefield, Lancashire, Chemist.

O.M. Mather, J., Blaydon Chemical Works, Blaydon-on-Tyne, Manager.

1904. Mather, J. Cecil, Works Chemist.

1900. Mather, Wm., c/o The Standard Chemical Co., St. Henri, Montreal, Canada, Chemist.

1907. Matheson, A. Greville E., Hawkesbury, Chinley, Derbyshire, Engineer.

1890. Matheson, W. J., c/o Cassella Color Co., 182, Front Street, New York City, U.S.A., Chemical Merchant.

1901. Mathew, W. E. B. de Vere, Dinham, Hillside Gardens, Wallington, Surrey, Analytical Chemist.

1900. Mathews, Dr. Jno. A., c/o Halcombe Steel Co., Syracuse, N.Y., U.S.A., Managing Director.

1898. Mathewson, E. P., Anaconda, Mont., U.S.A., Metallurgist.

1913. Mathuram, Dr. A., Guru Medical Hall, Trichinopoly, South India, Pharmacist.

1888. Mátos, Dr. Louis J., (Comms.) 103, North 19th Street, East Orange, N.J., and (Jnls.) c/o Cassella Color Co., 182–4, Front Street, New York City, U.S.A., Chemist.

1896. Matsui, G., 10, Nishikatamachi, Tokio, Japan, Chemical Engineer.

1912. Matthewman, Fred. P., Analyst's Office, L.B. and S.C. Railway Co., Brighton, Chief Chemist.

O.M. Matthews, Chas. G., 31, Stapenhill Road, Burton-on-Trent, Brewing Chemist.

1907. Matthews, Dr. F. E., Ashlawn, The Glebe, Blackheath, S.E., Technical Research Chemist.

1899. Matthews, Dr. J. Merritt, 5, Berwyn Street, East Orange, N.J., U.S.A., Professor of Chemistry and Dyeing.

1912. Maude, A. H., Wadham House, Toynbee Hall, Commercial Street, London, E., Technical Chemist.

1889. Mawdsley, W. H., G.P.O., Rockhampton, Queensland, Chemist.

1903. Maxim, Hudson, 698, St. Mark's Avenue, Brooklyn, N.Y., U.S.A., Chemist and Mechanical Engineer.

1894. Maxwell, Jno., Solway Chemical Works, Silloth, Cumberland, and (communications) English Street, Carlisle, Chemical Manure Manufacturer.

1903. Maxwell, Orin P., c/o West Virginia Pulp and Paper Co., Luke, Md., U.S.A., Chemist.

1911. May, Clarence E., 320, South Walnut Street, Bloomington, Ind., U.S.A.

1897. May, George H., 35, Graycliff Road, Newton Centre, Mass., U.S.A., Assistant Chemist.

1884. Mayenfeld, Dr. E. von Salis. *See* Salis-Mayenfeld, Dr. E. von.

1903. Mayer, Andrew, jun., 176, Sixth Avenue, Brooklyn, N.Y., U.S.A., Chemist.

1896. Mayfield, A. S., Oakdene, Newland Park, Hull, Analyst.

1892. Mayfield, H. B., Normanhurst, Mundy Street, Heanor, near Nottingham, Dyer.

1885. Mayhew, E. W. A., Manufacturing Chemist.

1900. Maywald, F. J., 89, Pine Street, New York City, U.S.A., Technical Chemist.

1909. Meanwell, Chas. W., 15, Woodlands Crescent, Muswell Hill Road, London, N., Analytical Chemist.

1898. Meeds, Alonzo D., 2424, Harriet Avenue, Minneapolis, Minn., U.S.A., Analytical Chemist.

1896. Meggitt, Loxley, Wheatsheaf Works, Alexandria, Sydney, N.S.W., Australia, Analytical Chemist.

1901. Meier, Dr. Franz, c/o Society of Chemical Industry in Basle, Basle, Switzerland, Chemist.

1888. Meikle, Jno., 8, Melrose Street, Great Western Road, Glasgow, Journalist.

1902. Melcher, Arthur C., 58, Bowen Street, Newton Centre, Mass., U.S.A., Research Chemist.

O.M. Meldola, Prof. R., F.R.S., 6, Brunswick Square, London, W.C., Professor of Chemistry.

1911. Mellerio, Lucien P., 5, Coburg Mansions, Brunswick Square, London, W.C., Technical Assistant.

1912. Melling, S. E., Lynton, Prestwich Park, Manchester, Analytical Chemist.

O.M. Mellon, W. W., Woodlands, Blackrock, Co. Dublin, Ireland, Manufacturing Chemist.

1910. Mellor, Dr. Jos. W., 19, Villas, Stoke-on Trent, Ceramic Chemist.

1884. Melville, D., 2, Melville Avenue, Delray, Detroit, Mich., U.S.A., Chemical Works Manager.

1909. Melville, Robt. L., Box 655, G.P.O., Auckland, N.Z., Chemist.

1912. Mennell, Harold, 41, Wolverton Road, Stony Stratford, Bucks, Analytical Chemist.

1893. Mensching, Dr. C., Mersey Chemical Works, Bromborough, Cheshire, Chemist.

O.M. Menzies, R. C., Inveresk Mills, Musselburgh, Scotland, Paper Maker.

1892. Mercer, C. A., 34, Camomile Street, London, E.C., Chemical Apparatus Maker.

1890. Merck, Dr. E., Darmstadt, Germany, Manufacturing Chemist.

1905. Merck, George, Merck and Co., 45, Park Place, New York City, U.S.A., Manufacturing Chemist.

1899. Merrill, Frank H., 2420, Ocean View Avenue, Los Angeles, Cal., U.S.A., Factory Superintendent.

1906. Merrils, Fred. J., 25, Figtree Lane, Sheffield, Analytical Chemist.

1909. Merriman, C. E. B., 74, Trent Boulevard, West Bridgford, Nottingham, Technical Chemist.

1909. Merriman, H. J., 244, Victoria Park Road, South Hackney, N.E., Research Chemist.

1905. Merrin, A. C., 194–200, Bishopsgate, London, E.C., Assistant Editor and Analyst.

1904. Merry, Jno. B., 74, Park Hill Road, Harborne, Birmingham, Metallurgical Chemist.
1903. Mersan, Ferdinand de, Fairfield, Chestnut Avenue, Boston Spa, Yorks, Chemist.
1905. Merz, Eugene, Newark, N.J., U.S.A., Superintendent, Heller and Merz Co.
1897. Meslans, Prof. M., 6, Rue de Navarin, Paris, France, Professor of Chemistry.
O.M. Messel, Dr. R., F.R.S., 147, Victoria Street, London. S.W., Chemical Manufacturer.
1913. Metcalf, Frederick A., 16, Offord Street, Passaic, N.J., U.S.A., Chemist.
1899. Metcalf, Howard F., Farr Alpaca Co., Holyoke, Mass., U.S.A.
1886. Metcalf, Jno., Moorfield Chemical Works, Altham, near Accrington, Tar Distiller.
1908. Metcalfe, Ernest D., Messrs. Curtis's and Harvey, Ltd., Cannon Street House, London, E.C., Secretary.
1906. Methley, Bernard, Ferndale, Moorgate, Rotherham, Yorks, Engineering Chemist.
1898. Metz, Herman A., P.O. Box 753, New York City, U.S.A., Chemical Merchant.
1905. Metzis, Josef, Anglicia Petroleum Co., Drohobycz, Galicia, Austria, Manager of Refinery.
1900. Mewborne, Robt. G., c/o Kentucky Tobacco Products Co., Louisville, Ky., U.S.A., Chemist.
1907. Meyer, Dr. Erwin, c/o Morgan and Wright, Detroit, Mich., U.S.A., Chemist.
1898. Meyer, Dr. Franz, c/o R. Wedekind und Co., Uerdingen a/Rhein, Germany, Metallurgical and Chemical Engineer.
1904. Meyer, Prof. Dr. Richard, Technische Hochschule, Braunschweig, Germany, Professor of Chemistry.
1902. Meyrick, L. J., 137, City Road, Birmingham, Assistant Analyst.
1912. Michie, Arthur C., The Wallsend Laboratories, Wallsend-on-Tyne, Technical Chemist.
1909. Michie, John L., 13, Falside, Paisley.
1907. Micklethwait, Miss Frances M. G., 15, St. Mary's Square, Paddington, W., Chemist.
1911. Middlemass, Alphonso, 59, Promenade, Portobello, Midlothian, Works Chemist.
1904. Mighill, Dr. Thos. A., 15, Exchange Street, Boston, Mass., U.S.A., Chemist.
1896. Miles, G. Wellington, Room 214, 88, Broad Street, Boston, Mass., U.S.A., Analytical Chemist.
1889. Milestone, W. C., 7, Heathfield Road, Wandsworth Common, S.W., Chemical Works Manager.
1912. Millar, Chas. J., c/o Turner, Morrison, and Co., Paint Dept., 6, Lyons Range, Calcutta, India, Analytical Chemist.
1899. Millar, Jas. H., P.O. Box 4975, Johannesburg, Transvaal, Manufacturing and Analytical Chemist.
1909. Millar, Jas. Hill, Chief Chemist's Laboratory, St. James' Gate Brewery, Dublin, Chemist.
1883. Miller, Dr. A. K., Kilvert's Buildings, Withy Grove, Manchester, Analytical Chemist.
O.M. Miller, E. V., Sugar Works, Chelsea, Auckland, New Zealand, Sugar Works Chemist.
1914. Miller, Eric F., Carnbuck Club, Perambur Barracks, Madras, India, Chemist.
1889. Miller, Geo., Thornlea, Beaconsfield Road, Farnworth, Widnes, Technical Chemist.
1893. Miller, Dr. Harry E., 305, Palm Avenue, Oakland, Cal., U.S.A., Chemist.
1883. Miller, Dr. H. von. *See* Miller-Aichholz, Dr. H. von.
1894. Miller, Dr. John A., 44–45, Lewis Block, Buffalo, N.Y., U.S.A., Consulting Chemist, State Analyst.
1888. Miller, J. Hopkins, 86, North Frederick Street, Glasgow, Dyeworks Chemist.
1889. Miller, Jno. Poynter, Sandilands Chemical Works, Aberdeen, Technical Chemist.
1901. Miller, Stuart B., c/o du Pont Powder Co., Emporium, Pa., U.S.A., Chemical Engineer.
1901. Miller, Dr. W. Lash, 50, St. Alban Street, Toronto, Canada, Associate Professor of Physical Chemistry.
1884. Miller, W. M., Caledonia Estate, Prof. Wellesley, Penang, S.S , Sugar Chemist.
1883. Miller-Aichholz, Dr. H. von, Beatrixgasse 32, Wien, Austria, Chemical Manufacturer.
1902. Milligan, R. E., New York Continental Jewell Filtration Co., 15, Broad Street, New York City, U.S.A., Chemical Engineer.
O.M. Mills, Prof. E. J., F.R.S., 64, Twyford Avenue, West Acton, W., Emeritus Professor of Technical Chemistry and Consulting Chemist.
1904. Mills, Dr. J. E., University of South Carolina, Columbia, S.C., U.S.A., Analytical and Consulting Chemist.
1905. Mills, Wm. Henry, 45, Wall Street, New York City, U.S.A., Merchant.
1905. Milne, Thomas, c/o The Gas Light and Coke Co., Ltd., Finsbury Court, Finsbury Pavement, London, E.C., Chemical Products Salesman.
1903. Milnes, Cresswell, The Cedars, Holborough, near Rochester, Cement Works Manager.
1887. Milnes, Edmund, Seedfield, Bury, Lancashire, Dyeing Extract Maker.
1902. Milnes, Ernest E., Park Print Works, Halifax, Yorks, Chemist.
1909. Mindeleff, Chas., c/o American Smelting and Refining Co., Maurer, N.J., U.S.A., Chemist.
1895. Miner, Harlan S., c/o Welsbach Light Co., Gloucester City, N.J., U.S.A., Technical Chemist.
1895. Mitchell, Chas. A., c/o Beaufoy and Co., South Lambeth Road, S.W., Analyst.
1898. Mitchell, G. D. H., c/o 559, Summer Avenue, Newark, N.J., U.S.A., Chemist.
1904. Mitsugi, R., c/o Tokio Gas Co., Senju Works, Senju, Tokio, Japan, Chemist.
O.M. Mitting, E. Kennard, 38, Harold Road, Norwood, S.E., Technical Chemist.
1908. Miyake, Hanzaburo, Ensuiko Sugar Factory, Shineisho, Formosa, Japan, Chemist.
1909. Miyoshi, K., Osaka Gas Works, Iwasakisho, Nishiku, Osaka, Japan, Engineer.
1909. Mock, Hugo, 220, Broadway, New York City, U.S.A., Lawyer.
1905. Modi, Dr. E. M., Meher Buildings, Tardeo, Bombay, India, Manufacturing and Analytical Chemist.
1910. Moe, Carl, Daisy, La., U.S.A., Chemist.
1906. Moe, Eldor H., Box 266, Salt Lake City, Utah, U.S.A., Chemist.
1911. Mohan, Richard T., 93, MacNab Street North, Hamilton, Ont., Canada, Chemist.
O.M. Mohr, Dr. B., 69A, Parliament Hill, Hampstead, N.W., Consulting Chemist and Metallurgist.
1894. Mole, Herbert B., Royal Albert Brewery, Queen's Road, Reading, Brewer.
1901. Mond, Dr. Albert L., c/o Hubers and Mond, 19, Southampton Buildings, Chancery Lane, London, W.C., Chemical Engineer.
1899. Mond, Emile S., 22, Hyde Park Square, London, W., Technical Chemist.
1891. Mond, Dr. Robt. L., Winnington Hall, Northwich. Chemist.
1906. Monier-Williams, G. W., 32, St. Leonard's Terrace, Chelsea, S.W.
1908 Monk, Chas. W., 102, Bloomfield Road, Plumstead, Kent, Chemist.
1909. Monk, Reginald H., 388, Grosvenor Avenue, Westmount, P.Q., Canada, Chemical Engineer.
1890. Moodie, Wm. E., Alexandria Works, Alexandria, Scotland. Analytical Chemist.
1905. Moody, Dr. Gerald T., Lorne House, North Dulwich, S.E., Barrister-at-Law.
1898. Moody, Dr. Herbert R., College of the City of New York, and (Journals) 330, Convent Avenue, New York City, U.S.A., Professor of Chemistry.
1903. Mooney, F. M., 118, Pembroke Road, Dublin, Chemical Manure Manufacturer.
1902. Mooney, Luke, Box 1085, Fort Worth, Texas. U.S.A.
1887. Moore, Chas. C., 33, Clarendon Road, Garston Liverpool, Chemist.
1901. Moore, Dr. Chas. W., c/o Crosfield and Sons, Ltd. Laboratory, Warrington, Chemist.
1907. Moore, Ernest P., c/o The Steel Co. of Canada, Hamilton, Ont., Canada, Chemist.

1911. Moore, Ernest W., c/o Messrs. T. G. Tickler, Ltd., Southall, Middlesex, Analytical Chemist.

1902. Moore, Fred., Victoria Chemical Co., Ltd., Victoria, B.C., Canada, Manufacturing Chemist.

1906. Moore, F. H., Messrs. G. H. Ogston and Moore, 87–89, Aldgate, London, E., Analytical Chemist.

1892. Moore, Dr. Geo. D., 201, Salisbury Street, Worcester, Mass., U.S.A., Professor of Chemistry.

1914. Moore, Harold, c/o Mirrlees, Bickerton, and Day, Hazel Grove, Stockport, Chemist.

1912. Moore, Joseph W., Kinderton House, Runcorn, Works Chemist.

1905. Moore, Leslie R., 14, Elm Street, Concord, Mass., U.S.A., Chemist.

1899. Moore, Quintin, jun., c/o Wm. Beardmore and Co., Ltd., Parkhead Forge, Glasgow, Works Manager.

1885. Moore, R. T., 142, St. Vincent Street, Glasgow, Mining Engineer.

1899. Moore, Dr. Russell W., 121, Madison Avenue, New York City, U.S.A., Chemist.

1890. Moore, Thos., 213, Heathfield Road, Birmingham, Analytical Chemist.

1910. Moorhouse, Samuel, 138, New Road, Blackley, Manchester, Secretary and Oil Specialist.

1905. Moorwood, F. Colin, c/o W. H. Dyson, The Amalgams Co., Ltd., Attercliffe Road, Sheffield, Steel Manufacturer.

1903. Moran, Geo. A., 98, Massachusetts Avenue, North Andover, Mass., U.S.A., Chemist.

1890. Mordle, F. Dare, Guilderoy, Matlock Bath, Derbyshire, Starch Manufacturer.

1902. More, Andrew, Ellesmere, King's Road, Walton-on-Thames, Analytical Chemist.

1908. Morfey, Harold, c/o The Mitchell Main Colliery Co., Wombwell, near Barnsley, Yorks, Manager of By-Products Works.

1901. Morgan, Dr. Gilbert T., Royal College of Science for Ireland, Dublin, Ireland, Professor of Chemistry.

1905. Morgan, Prof. Jerome J., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Instructor in Engineering Chemistry.

1912. Morgan, Sidney, Petaling Estate, Selangor, Federated Malay States, Analytical Chemist.

1906. Morgan, Thos., "Meirion," Dovedale Road, Mossley Hill, Liverpool, Manufacturing Chemist.

1898. Morgan, T. M., 370, Wood Avenue, Westmount, Quebec, Canada, Cement Works Manager.

O.M. Moritz, Dr. E. R., 45, Great Tower Street, London, E.C., Brewing Chemist.

1885. Morley, Dr. H. Forster, 5, Lyndhurst Road, Hampstead, N.W., Professor of Chemistry.

1902. Morrell, Dr. R. S., Messrs. Mander Bros., Colour and Varnish Works, Wolverhampton, Chemist.

1884. Morrice, Jas. A., 1, Prince's Terrace, Dowanhill, Glasgow, Starch and Gum Manufacturer.

1906. Morris, A. H., c/o Magee, Marshall, and Co., Crown Brewery, Bolton, Lancs, Brewer.

1898. Morris, Edgar F., 60, Millgate, Stockport, Research Chemist.

1897. Morris, Harry, The Hall, Hexthorpe, Doncaster, Chemical Merchant.

1890. Morris, Herbert N., Gorton Brook Chemical Works, Manchester, Technical Chemist.

O.M. Morris, J. Haydn. *See* Haydn-Morris, J.

1908. Morris, Wm. J., 31, Prince Alfred Road, Wavertree, Liverpool, Chemist.

1911. Morrison, G. R., Oficina Reducto, Santa Catalina, Iquique, Chile, Chemist.

1910. Morrison, J. A. S., c/o Clark, Son, and Morland, Ltd., Glastonbury, Somerset, Leather Chemist.

1910. Morrison, John W., Gas Offices, Sheffield, Gas Engineer.

1902. Morrison, Jos., Wellfield, Farnworth, Widnes, Manager.

1906. Merrow, Jas. M., 71, Tache Avenue, Norwood Grove, St. Boniface, Man., Canada, Analytical Chemist.

1901. Morse, Willard S., Seaford, Del., U.S.A., Manager.

1904. Morson, Thos. D., 14, Elm Street, Gray's Inn Road, London, W.C., Chemist.

1906. Morson, T. Pierre, 14, Elm Street, Gray's Inn Road, London, W.C., Chemical Manufacturer.

1907. Morton, George A., 37, Hillside Road, Menlove Avenue, Mossley Hill, Liverpool, Chemist.

1897. Morton, Jno., North Road, St. Helens, Lancashire, Analytical Chemist.

1902. Mosbaugh, F. R., c/o Anglo-Canadian Leather Co., Huntsville, Ont., Canada, Chemist.

1911. Mosenthal, E. Macqueron de, 9, Rue Neuve, Versailles, France, Chemist.

1912. Moss, J. Miles, jun., c/o Lever Bros., Ltd., Eastern Avenue, Toronto, Canada, Chemist.

1894. Moszczenski, J. B., 216, Ovington Avenue, Brooklyn, N.Y., U.S.A., Consulting Chemist.

1897. Motion, Jno., c/o The Joseph Dixon Crucible Co., Jersey City, N.J., U.S.A., Assistant Superintendent.

1887. Moul, Frank, Aldersgate Chemical Works, Southall, Technical Chemist.

1884. Moult, J., 3, Gladstone Terrace, Gateshead-on-Tyne, Secretary.

1898. Moulton, Prof. Chas. W., Vassar College, Poughkeepsie, N.Y., U.S.A., Professor of Chemistry.

1905. Moulton, Rt. Hon. Sir J. Fletcher, F.R.S., 57, Onslow Square, London, S.W., Lord Justice of Appeal.

1892. Mount, Edw., Oaklands, Aughton, near Ormskirk, Assistant Secretary (United Alkali Company).

1905. Mrazsek, F. M., 23, West Cromwell Road, London, S.W., Consulting Chemist.

1904. Muckenfuss, A. M., University, Miss., U.S.A., State Chemist.

1907. Mueller, Dr. Carl, Alte Weinsteige 48, Stuttgart, Germany, Chemist.

1890. Muir, Jas. Stanley, 23, Lilybank Gardens, Glasgow, Chemist.

O.M. Müller, Dr. H., F.R.S., 13, Park Square East, Regent's Park, London, N.W., Research Chemist.

1913. Mumford, E. Moore, 75, High Street, Chorlton on Medlock, Manchester, Bio-chemist.

1896. Mundy, Lionel, 27, Merton Road, Kensington, W., Importer of Unfermented Wines.

1887. Munroe, Prof. Chas. E., George Washington University, Washington, D.C., U.S.A., Professor of Chemistry and Dean.

1900. Munsell, Dr. Chas. E., c/o Devoe and Raynolds Co., 110, Horatio Street, New York City, U.S.A., Colour Chemist.

1900. Munton, Fred. T., Craigmore, Winsford, Cheshire, A.R.S.M., Analytical Chemist.

1904. Murdoch, Alexander, 507, Alexandra Parade, Dennistoun, Glasgow, Analytical Chemist.

1912. Murdoch, Barclay B., c/o Messrs. Wm. Gossage and Sons, Soap Works, Widnes, Lancs., Technical Chemist.

1886. Murdoch, R. H. M., Norwood, Saltcoats, Ayrshire, Explosives Chemist.

1899. Murphy, Albert J., 3 and 4, Queen Square, Leeds, Brewer's Chemist.

1906. Murphy, Frederic W., Standard Sugar Refinery, Granite Street, South Boston, Mass., U.S.A., Chemist.

1901. Murray, Benjamin L., c/o Merck and Co., Rahway, N.J., U.S.A., Chemist.

1903. Murray, Chas. B., 407, Perry Payne Building, Cleveland, Ohio, U.S.A., Chemist.

1914. Murray, John E., c/o Emerson Drug Co., 64, Spadina Avenue, Toronto, Canada, Laboratory Superintendent.

1898. Murray, Rd., c/o Brotherton and Co., Ltd., Ammonia Works, Holmes Street, Leeds, Analyst.

1908. Murray, Dr. Thos. J., Municipal Technical School, Wolverhampton, Lecturer on Chemistry.

1905. Murray, Wm. Wallace, Chemist.

1905. Murrill, Dr. Paul I., c/o U.S. Rubber Co., 11th Avenue and 58th Street, New York City, U.S.A., Representative.

O.M. Muspratt, Dr. E. K., Seaforth Hall, near Liverpool, Alkali Manufacturer.

1894. Muspratt, Max, The Grange, Fulwood Park, Liverpool, Technical Chemist.

O.M. Muspratt, S. K., 9, Church Street, Flint, North Wales, Alkali Manufacturer.

1907. Musso, Louis A., Box 956, G.P.O., Sydney, N.S.W., Australia, Technical Chemist.

1895. Muurling, I. J. R., 117, Hudson Street, New York City, U.S.A., Dyestuff Importer.

1911. Myers, Ernest M., Sharrow, Basford Park, Stoke on Trent, Coke Oven Manager and Chemist.

1891. Myers, Dr. Wm. S., 71, Nassau Street, New York City, U.S.A., Director.

N

1902. Naef, Dr. Ernest E., 17, Park Road, Clydach, Swansea, South Wales, Chemist.

1913. Nagase, Denzo, 36, Flanchford Road, Ravenscourt Park, W., Engineer.

1908. Nagle, J. C., Fern Bank, Edge Lane, Stretford, Manchester, Glucose and Starch Manufacturer.

1913. Nair, Valliyil G., Calico Mills, Ahmedabad, India, Chemist and Colourist.

1897. Nairn, Michael, Dysart House, Fife, Linoleum Manufacturer.

1909. Nakai, S., Miike Colliery Office, Omuta-machi, Chikugo, Japan, Engineer.

1903. Nakayama, T., c/o Fuji Paper Co., Mill No. 5, Yebetsu, Hokkaido, Japan, Chemist.

1901. Nanabhai, Krishnalal, "Laxmi Nivas," Girgaum Back Road, Bombay, India, Technological Chemist.

1912. Nanavati, Balabhai J., Rickey Road, Ahmedabad, India, Oil Manufacturer.

1893. Napier, Jno. W., Gas Works, Alloa, Scotland, Manager and Chemist.

1904. Napper, Sidney S., c/o S. Courtauld and Co., Ltd., Foleshill Road, Coventry, Chemist.

1897. Nash, L. Myddleton, Westlands, Princess Road, Finsbury Park, N., Works Chemist.

1910. Nash, N. C., Treleaven, Darling Street, Balmain East, Sydney, N.S.W., Works Chemist.

1908. Nasmith, M. E., 1, Ferndale Avenue, Toronto, Canada, Baker.

1900. Nathan, Lt.-Col. Sir Frederic L., R.A., The Royal Palace Hotel, Kensington, W., Superintendent, Nobel's Explosives Works.

1907. Nauckhoff, Sigurd, c/o Nitroglycerin Aktiebolaget, Vinterviken, Stockholm, Sweden, Chemical Engineer.

O.M. Naylor, W. A. H., The British Drug Houses, Ltd., 22–30, Graham Street, City Road, London, N., Manufacturing Chemist.

1909. Neal, C. S., Acme White Lead and Colour Works, Detroit, Mich., U.S.A., Manager.

1899. Neate, Percy J., 49, Frognal, Hampstead, N.W., Director of Cement Co.

1905. Neech, Herbert R., Doddington Lane, Swallowbeck, Lincoln, Chemical Engineer.

1905. Needham, Edward R., c/o The Northern Chemical Co., 16, Blythswood Square, Glasgow, Manufacturing Chemist.

1905. Neff, Robert W., 22, India Square, Boston, Mass., U.S.A., Chemical Manufacturer.

1906. Neil, Dr. Archibald A., c/o Brunner, Mond, and Co., Caxton House, Westminster, S.W., Chemical Engineer.

1890. Neill, Geo. D., 78, Drum Frochar Road, Greenock, Sugar Refiner.

1898. Neilson, Alex. McG., Umbilo, Durban, Natal, Analytical Chemist.

1911. Neilson, R. G., c/o Burmah Oil Co., Ltd., P. Box 67, Rangoon, Burmah, Assistant Works Manager.

1910. Neiman, Howard S., Suite 1579, 50, Church Street, New York City, U.S.A., Patent Attorney.

1902. Neish, Dr. Arthur C., Columbia University, New York City, U.S.A., Chemist.

1911. Nello, Vincent, Baldwin's Hill, Loughton, Artists' Colour Manufacturer.

1897. Nelson, Walter, Emscote Mills, Warwick, Gelatin Manufacturer.

1913. Nesbitt, Cosby T., 19, Osborne Road, Brimsdown, Middlesex, Metallurgical Chemist.

1906. Nestell, Raymond J., c/o Western Precipitation Co., 1016, West Ninth Street, Los Angeles, Cal., U.S.A., Analytical Chemist.

1902. Neumann, Dr. Edgar, 7 and 8, Idol Lane, London, E.C.

1903. Neumann, Dr. Max, Dambachthal 9, Wiesbaden, Germany.

O.M. Newall, F. S., Washington Station R.S.O., Co. Durham, Chemical Manufacturer.

1905. Newall, Jos., Hill Cliffe, Heath Road, Runcorn, Cheshire, Chemist.

1889. Newberry, Spencer B., Sandusky Portland Cement Co., Sandusky, Ohio, U.S.A., Manager.

O.M. Newlands, W. P. R., 10, Cricklade Avenue, Streatham Hill, S.W., Sugar Chemist.

O.M. Newton, Jno., Verney Road, Rotherhithe New Road, London, S.E., Manure Manufacturer.

1912. Newton, Leonard O., 41, Bennett Park, Blackheath, S.E., Analytical Chemist.

1901. Nibelius, Axel W. T., c/o Neptune National Powder Co., Emporium, Pa., U.S.A., Chemist.

1904. Nichols, C. W., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.

1905. Nichols, E. Remington, 25, Broad Street, New York City, U.S.A., Treasurer (Nichols Chemical Co.).

1888. Nichols, Dr. Wm. H., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.

1905. Nichols, W. H., jun., 25, Broad Street, New York City, U.S.A., Chemical Manufacturer.

1904. Nicholson, Wilfred E., Hunslet Chemical Works, Leeds, Chemical Manufacturer.

1897. Nicholson, Wm. J., Ardeer, Stevenston, Ayrshire, Chemist.

1903. Nicoll, Frank, 28, Coudray Road, Southport, Chemist.

1905. Nieghorn, Albert, 120, Mill Street, Toronto, Canada, Agent.

1900. Nield, J. H., c/o General Chemical Co., Edgewater, N.J., U.S.A., Superintendent.

1898. Nightscales, Geo., 642, Holderness Road, Hull, Oil Merchant.

1899. Nihoul, Dr. Edw., 204, Rue St. Laurent, Liège, Belgium, Director of the Liège Tannery School.

O.M. Nimmo, Jas., 35, Whitworth Road, South Norwood, S.E., Analytical Chemist.

1907. Nims, H. E., c/o The Fiberloid Co., Indian Orchard, Mass., U.S.A., Chemist.

1885. Nishigawa, T., 20, Hirakawa Cho, Go Chome, Tokyo, Japan, Works Director and Chemical Engineer.

1898. Nishikawa, Prof. Dr. T., Dept. of Applied Chemistry, Kyushu Imp. University, Fukuoka, Japan, Prof. of Applied Chemistry.

1908. Noble, Sir Andrew, Bart., K.C.B., F.R.S., Jesmond Dene House, Newcastle-on-Tyne.

O.M. Nölting, Prof. Dr. E., 27, Lazarethstrasse, Mülhouse, Alsace, Germany, Professor of Chemistry.

O.M. Norman, Sir Frederick J., Lyndhurst, Higher Runcorn, Cheshire, Chemical Manufacturer.

1892. Norman, J. T., 23, Leadenhall Street, London, E.C., Consulting Chemist.

1913. Norman, T. Stanley, Lyndhurst, Runcorn, Cheshire, Chemical Manager.

1890. Norman-Bott, Dr. Wm., 17, St. Helen's Place, London, E.C., Consulting Chemist.

1908. Norris, Wm. H. H., 41, Aldborough Road, Ilford, Essex, Chemist.

1902. North, Barker, 33, Ashgrove, Great Horton Road, Bradford, Assistant Professor of Chemistry.

1909. Northcote, Reginald S., 28, Wellington Street East, Toronto, Chemist.

O.M. Northing, J., The Murrough, Wicklow, Ireland, Technical Chemist.

1905. Norton, Arthur L., 36, Purchase Street, Boston, Mass., U.S.A., Dyestuff Merchant.

O.M. Norton, Dr. S. A., 363, East Town Street, Columbus, Ohio, U.S.A., Professor of Chemistry (Ohio State University).

1911. Norton, Samuel J., 22, Bushnell Road, Balham, S.W., Engineer and Manager.

1887. Norton, Dr. T. H., c/o Wm. Bryce, 54, Lothian Street, Edinburgh, U.S. Consul.
1899. Noyes, Henry, c/o Noyes Bros., 153 7, William Street, Melbourne, Victoria, Engineer.
1901. Noyes, Prof. Wm. A., University of Illinois, Urbana, Ill., U.S.A., Editor (J. Amer. Chem. Society).

O

1910. Oakden, W. E., 2, Gledhow Terrace, South Kensington, S.W., Director of Research Laboratory.
1905. Oakes, F. J., jun., 141, Milk Street, Boston, Mass., U.S.A., Secretary, Oakes Manufacturing Co.
1904. Oberländer, Dr. Otto, 29, Queen Street, London, E.C., Research and Consulting Chemist.
1904. O'Brien, Claude H., Malgrave, Cairns, North Queensland, Supervising Chemist.
1900. O'Brien, Frederick, Lynwood, Grange Road, Bishopsworth, near Bristol, Analytical Chemist.
1905. Oburg, W. F., 33, Broad Street, Boston, Mass., U.S.A., Assistant Treasurer (Merrimac Chem. Co.).
1902. Ockel, Reinhold, Schumannstrasse 31, Bonn a Rhein, Germany, Technical Chemist.
1901. O'Connor, Chas. P., 7, Fairfield Street, Montclair, N.J., U.S.A., Analytical Chemist.
1908. O'Day, John, 32, India Street, Boston, Mass., U.S.A., Dyestuff and Chemical Merchant.
1888. Oddy, Robert W., Abbey Street, Toad Lane, Rochdale, Chemist.
1911. Oehler, Prof. John, Carlstadt, N.J., U.S.A., Assoc. Professor of Chemistry (Columbia University).
1908. Ogilvie, Jas. P., Homedale, Hendon Lane, Church End, Finchley, N., Chemist.
1901. Ogston, Alex. G., Heath Park, near Aberdeen, Soap Manufacturer.
1903. Ohlenschlager, J. G., jun., Shanghai House, Botolph Lane, London, E.C., Chemical Merchant.
1905. Ohliger, Willard, c/o F. Stearns and Co., Detroit, Mich., U.S.A., Chemist.
1907. Oke, Alfred W., 32, Denmark Villas, Hove, Sussex, Solicitor.
1884. Oliver, F., 31, Horsley Hill Road, Westoe, South Shields, Analytical Chemist.
1912. Oliver, Ralph R., c/o Southern Fibre Co., Portsmouth, Va., U.S.A., Paper Chemist.
1888. Oliver, Wm. Letts, 251, Vernon Street, Oakland, Cal., U.S.A., Mining Engineer.
1910. Oliver, Willie, 30, Woodstock Street, Spotland, Rochdale, Works Chemist.
1914. Ollé, Arch. D., "Kareema," Charlotte Street, Ashfield, N.S.W., Australia, Electro-therapeutist.
O.M. Ollerenshaw, S., 96, Davyhulme Lane, Urmston, Manchester, Technical Chemist.
1906. Olmsted, Fred. A., c/o Willamette Pulp and Paper Co., Oregon City, Oregon, U.S.A., Chemical Engineer.
1904. Olney, Prof. L. A., 118, Riverside Street, Lowell, Mass., U.S.A., Professor of Chemistry and Dyeing.
1902. O'Neill, Chas., c/o Bleachers' Association, Ltd., 4, Norfolk Street, Manchester, Chemist and Colourist.
1907. Oppen, Wm. A., Vera Chemical Co., Stoneham, Mass., U.S.A., Chemist and Superintendent.
1905. Ormandy, Dr. W. R., 53a, Barton Arcade, Manchester, Consulting Chemist.
1898. Ormerod, Dr. Ernest, 62, Dale Street, Liverpool, Consulting and Analytical Chemist.
1894. Ormerod, John, Globe Leather Works, Castleton, Manchester, Tanner and Currier.
O.M. Orr, A., 80, Hunter Street, Sydney, New South Wales, Analytical Chemist.
O.M. Orr, J. B., Crossacres, Woolton, Liverpool, Chemical Manufacturer.
1899. Orr, Thos. W., c/o W. Orr, 26, Renfield Street, Glasgow; and (Journals) Lethnot, Burnside, Rutherglen, Glasgow, Chemist.
1907. Ortved, Niels C., c/o Hiram Walker and Sons, Ltd., Walkerville, Ont., Canada, Chemist and Fermentologist.
1900. Osbourne, Jno. P., 6, Garrioch Drive, Maryhill, Glasgow, Analytical Chemist.
1900. O'Shaughnessy, Francis R., 42, Temple Street, Birmingham, Consulting Chemist.
1885. O'Shea, Prof. L. T., Dept. of Applied Science, St. George's Square, Sheffield, Professor of Applied Chemistry (University of Sheffield).
1912. Osius, George, Canadian Ammonia Co., Ltd., Foot of Meldrum Street, Detroit, Mich., U.S.A., Secretary and Treasurer.
1883. O'Sullivan, J., High Bank, Burton-on-Trent, Brewing Chemist.
1912. Oswald, Jacob, c/o Messrs. Fels and Co., 73rd Street and Woodland Avenue, Philadelphia, Pa., U.S.A., Soap Works Technical Manager.
1905. Otsuki, Prof. Chiri, Chemical Laboratory, Kyoto Imperial University, Kyoto, Japan, Professor of Applied Chemistry.
1898. Oushkoff, John P., Warwarka 5, Moscow, Russia, Chemical Manufacturer.
1906. Oxley, Horace F., c/o Natal Soap Works Co., Durban, South Africa, Chemist.
1908. Oxley, John C., Claycroft, Guiseley, near Leeds, Aniline Colour Merchant.

P

1904. Packard, C. T., Millbank, Bramford, near Ipswich, Manager of Chemical Works.
1904. Page, Edwin P., Glenroy, Highland Grove, Worksop, Notts, Chemist.
1886. Pagès, Albert, 34, Boulevard Henri IV., Paris, Technical Chemist.
1892. Paine, Augustus G., 200, Fifth Avenue, New York City, U.S.A. President of Paper Making Co.
1906. Palm, Otto G., 41, Colborne Street, Toronto, Canada, President (Atteaux Dye and Chemical Co.).
1903. Palmenberg, O. W., 50, East 41st Street, New York City, U.S.A., Consulting Chemist and Fuel Engineer.
1902. Palmer, Fred. G., Chemist and Acid Superintendent.
1887. Palmer, T. Chalkley, c/o American Dyewood Co., Chester, Pa., U.S.A., Manufacturing Chemist.
1887. Palmer, Thos. C., c/o W. J. Fraser and Co., Ltd., Dagenham, Essex, Engineer.
1907. Palmer, Wm. J., c/o Pinchin, Johnson, and Co., Ltd., Pinchin's Wharf, Silvertown, E., Analytical Chemist.
1911. Paniker, Ramni, Consejo de Ciento 288, 2°, 2ª, Barcelona, Spain, Leather Trades Chemist.
1898. Parker, Charles H., Rose Cottage Works, Whitmore Reans, Wolverhampton, Chemist.
1891. Parker, Edw., Laburnum House, Rushford Avenue, Levenshulme, Manchester, Analytical Chemist.
1894. Parker, Dr. J. Gordon, Leathersellers' Technical College, 176, Tower Bridge Road, London, S.E., Principal.
1897. Parker, Prof. Matthew A., University of Manitoba, Winnipeg, Canada, Professor of Chemistry.
1901. Parker, Richard H., 147, Seymour Avenue, Newark, N.J., U.S.A., Analytical Chemist.
O.M. Parker, Thos., Severn House, Iron-bridge, Salop, Electrical Engineer.
1894. Parker, Thos. J., 25, Broad Street, New York City; and (Journals) Bayonne, N.J., U.S.A., Chemical Works Manager.
1903. Parker, Wm. B., 1, Murray Road, Rugby, Chief Chemist (British Thomson-Houston Co., Ltd.).
1901. Parker, Dr. Wm. Huntington, 177, State Street, Boston, Mass., U.S.A., Chemist (U.S. Appraisers).
1901. Parkes, Albert E., 43, Whitehorse Street, Stepney, E., Analytical Chemist.
1898. Parrish, Saml., 80, Grange Avenue, Chapeltown Road, Leeds, Teacher of Chemistry.
1914. Pascoe, Charles F., Canadian Steel Foundries, Ltd., Longue Pointe Works, Montreal, Canada, Metallurgist.

1901. Pass, James, Onondaga Pottery Co., Syracuse, N.Y., U.S.A., Pottery Manufacturer.

1909. Passmore, Dr. Francis W., 81, Queen Victoria Street, London, E.C., Consulting Chemist.

1902. Patch, Prof. Jas. A., Syrian Protestant College, Beirût, Syria, Professor of Chemistry.

1897. Patchett, Col. Jas., Oakworth, Hadley, Wellington, Salop, Ironmaster.

1884. Paterson, John, Belle Isle Place, Workington, Cumberland, Mechanical Engineer.

1887. Paton, J. M. C., Messrs. Manlove, Alliott, and Co., Ltd., Nottingham, Mechanical Engineer.

1901. Patterson, Chas. A., Woodbury, N.J., U.S.A., Analytical Chemist.

O.M. Patterson, Geo., c/o The Manbré Saccharine Co., Ltd., Fulham Palace Road, Hammersmith, W., Technical Chemist.

1909. Patterson, G. H., Ivanhoe, Linden Grove, West Hartlepool, Works Manager.

1893. Patterson, Harry J., College Park, Prince George's Co., Md., U.S.A., Agricultural Chemist.

O.M. Patterson, T. L., Maybank, Finnart Street, Greenock, Sugar Works Manager.

1902. Patterson, Wm. Hamilton, Monksferry Chemical Laboratory, Birkenhead, Technical Chemist.

O.M. Pattison, Jas., Drimnamona, Kilmalcolm, Chemical Merchant.

1889. Pattison, Percy J., St. Budeaux, Devonshire Road, Hornchurch, Essex, Technical Chemist.

1909. Patton, H. G., c/o Fred Rueping Leather Co., Fond du Lac, Wis., U.S.A., Chemist.

1904. Patz, E. O., 215, Water Street, New York City, U.S.A., Manager, Berlin Aniline Works.

1908. Paul, David M., c/o Japanese Explosives Co., Hiratsuka, Sagami, Japan, Chemist.

1891. Paul, Jas. H., 11, Glenluce Road, Blackheath, S.E., Analytical Chemist.

1900. Paul, Dr. L. Gordon, Market Hall Chambers, King Street, Huddersfield, Consulting Chemist.

1904. Payne, A. G. C., 6, Bradford Place, Penarth, near Cardiff, Chemist.

O.M. Payne, J. B., 13, Mosley Street, Newcastle-on-Tyne, Manufacturing Chemist.

1912. Peachey, S. J., 8, Halesden Road, Heaton Chapel, Stockport, Lecturer in Chemistry.

1910. Peacock, Samuel, Suite 910, 165, Broadway, New York City, U.S.A., Chemist and Metallurgist.

1912. Pearce, Geoffrey V., 14, Park Crescent, Portland Place, London, W., Chemical Manufacturer.

1894. Pearce, Jas. Stanley, Priest's Mere, Tadworth, Surrey, Chemical Manufacturer.

1897. Pearce, Richard, 6, Beach Lawn, Waterloo, Liverpool, Metallurgist.

1883. Pearce, W., M.P., Chemical Works, Bow Common, London, E., Chemical Manufacturer.

1903. Pearcy, A. C., 43, Marlborough Mansions, Cannon Hill, London, N.W., Director, Explosives Co.

1904. Pease, Fred N., P.O. Box 503, Altoona, Pa., U.S.A. Chemist.

O.M. Péchiney, A. R., Villa Les Rochers, Hyères (Var), France, Chemical Engineer.

1898. Peck, Dr. Ernest L., High Lawn, Bromborough, Cheshire, Chemist.

1894. Peden, Jno., 11, Duff Street, Greenock, Analytical Chemist.

O.M. Pedler, Sir Alexander, C.I.E., F.R.S., 28, Stanhope Gardens, Queen's Gate, London, S.W., Director of Public Instruction (retired).

1886. Pedler, J. R., 47, Tregunter Road, South Kensington, S.W., Clerk.

1906. Peile, Henry, Millburn House, Newcastle-on-Tyne, and (Journals) c/o F. J. Willott, Victoria Garesfield Colliery, Rowlands Gill, Co. Durham, Colliery Owner.

1899. Pell, A., 7, Elphinstone Circle, Bombay, India, Chemist.

1897. Pellew, Chas. E., 111, East 78th Street, New York City, U.S.A., Adjunct Professor of Chemistry.

1912. Pellizza, Dr. A., Sta. Rosa, Necoxtla, Estada Vera Cruz, Mexico, Colourist.

1904. Pelly, Russell George, 3, Wingate Road, Hammersmith, W., Analytical Chemist.

1914. Penfold, A. R., Sydney Technical College, Harris Street, Sydney, N.S.W., Australia, Chemist.

1896. Penney, Mulgrave D., 11, High Street, Hull, Analytical Chemist.

1890. Pennock, J. D., c/o Solvay Process Co., Syracuse, N.Y., U.S.A., Technical Chemist.

1885. Pentecost, S. J., Alexandra Mount, Mapperly Hill, and (Journals) Lenton Works, Nottingham, Lace Dresser.

1887. Pentermann, H. T., 37, Clifton Crescent, Peckham. S.E., Brewing Chemist.

1892. Peploe, D. H. T., Underriver House, Sevenoaks, Kent.

1885. Perkin, A. G., F.R.S., Grosvenor Lodge, Grosvenor Road, Leeds, Technical Chemist.

1898. Perkin, Dr. F. Mollwo, 199, Piccadilly, London, W., Head of Chemical Department, Borough Polytechnic.

1887. Perkin, Dr. W. H., F.R.S., 5, Charlbury Road, Oxford, Professor of Chemistry.

1893. Perkins, T. S., 30, Tiffany Place, Brooklyn, N.Y., U.S.A., Chemist.

1912. Perrin, Wm. R., jun., 530, King Street East, Toronto, Canada, Secretary and Treasurer.

1901. Perry, Chas. M., Greene, Kent County, R.I., U.S.A. Bleach and Dyeworks Chemist.

1887. Perry, David, 15, Woodlands Terrace, Glasgow, and (Journals) Forth and Clyde Chemical Works, Nitshill, near Glasgow, Manufacturing Chemist.

1895. Perry, Jos. H., 276, Highland Street, Worcester, Mass., U.S.A., Teacher of Chemistry.

1903. Perry, M. J. T., Australian Drug Co., O'Connell Street, Sydney, N.S.W., Australia, Manufacturing Chemist.

1903. Perry, Robt. Swain, 3500, Grays Ferry Road, and (Journals) Station D., Philadelphia, Pa., U.S.A., President (Harrison Bros. and Co.).

1897. Peter, Dr. A. H., 2508, Broadway, New York City, U.S.A., Chemist.

1908. Peters, John M., c/o National Lead Co., 111, Broadway, New York City, U.S.A., White Lead Manufacturer.

1909. Petrie, A. Swanston, c/o Gibbs and Co., Iquique, Chile, S. America, Analytical Chemist.

1903. Petrie, Dr. Jas. M., The University, Sydney, N.S.W., Australia, Chemist.

1902. Petsche, B. W., 60, Glenwood Avenue, Yonkers N.Y., U.S.A., Chemist.

1906. Pettee, Chas. L. W., c/o Hartford Laboratory Co., Hartford, Conn., U.S.A., Chemist.

1892. Pettigrew, Robert, c/o Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Electro-Chemist.

1902. Pettitt, Alf., 457, State Street, Brooklyn, N.Y., U.S.A., Chemist.

1913. Petty, G. N., 6, Kingsthorpe Road, Sydenham, S.E., Chemist.

1913. Pfleiderer, B. J., Westwood Works, Peterborough, Engineer.

1912. Pfleiderer, Kurt, Westwood Works, Peterborough, Mechanical Engineer.

1888. Philip, Arnold, Chemical Laboratory, H.M. Dockyard, Portsmouth, Electro-Metallurgist and Electrical Engineer.

1908. Philip, Prof. James C., Imperial College of Science and Technology, South Kensington, S.W., Professor of Physical Chemistry.

1903. Philipp, Herbert, 152. High Street, Perth Amboy, N.J., U.S.A., Chemist and Electrochemical Engineer.

1912. Phillips, G. A., Laboratory, The Powell Duffryn Co., Aberdare, Mon., Chemist.

O.M. Phillips, Harcourt, Lynwood, Turton, Lancs., Analytical Chemist.

1911. Phillips, Henry A., Royal Gunpowder Factory, Waltham Abbey, Essex, Chemist.

1910. Phillips, Prof. Percy P., Thomason College, Rurki, United Provinces, India, Professor of Chemistry.

1895. Phillips, S. Chas., 47, Cannon Street, London, E.C., Chemical Engineer.
1911. Phillipa, William E., 45, Ben Lamond Avenue, Toronto, Canada.
1898. Phillips, Wm. H., 100, Milton Avenue, East Ham, E., Soap Works Chemist.
1911. Philpotts, Wilfred C., 35, Sandford Avenue, Toronto, Canada, Gasworks Chemist.
1894. Picard, Hugh F. K., 44, London Wall, London, E.C., Metallurgist.
1904. Pickard, Glenn H., c/o American Linseed Co., 110th Street and Torrence Avenue, South Chicago, Ill., U.S.A., Manager of Oils Dept.
1905. Pickard, Greenleaf W., Amesbury, Mass., U.S.A., Electrical Engineer.
1902. Pickard, Dr. R. H., Billinge View, Blackburn, Teacher and Analyst.
1904. Pickup, Edgar H., 348, Great Clowes Street, Higher Broughton, Manchester, Calico Printer.
1913. Pierce, Jas. B., jun., Engineers' Club, Scranton, Pa., U.S.A., Chemist, Barium Products Co.
1888. Pilkington, G., 9, Knowsley Street, Bury, Lancashire, Analytical Chemist.
1893. Pilley, Thos. W., 33, Grove Hill Road, Denmark Hill, S.E., Analytical Chemist.
1894. Pilling, John E., 229, Hornby Road, Blackpool, Chemist.
1906. Pincott, Emile S., 222, St. James Street, Montreal, Canada, Manager (Nichols Chemical Co. of Canada, Ltd.).
1910. Pinnock, Douglas R., c/o The Nucoa Butter Co., 4th Street and Avenue A, Bayonne, N.J., U.S.A., Chemist.
1905. Pinnock, H. T., 11, Fountain Road, Edgbaston, Birmingham, Chemist.
1883. Pipe, Jas., Woodburn, Irvine, Scotland, Chemical Manufacturer.
1896. Piper, Walter E., Boston Rubber Shoe Co., Malden, Mass., U.S.A., Chemist.
1910. Pisart, F., 74, Avenue Blonden, Liège, Belgium, Chemical Engineer.
1907. Pitman, Brig.-Gen. John, 167, Berkeley Avenue, Orange, N.J., U.S.A., U.S. Army (retired).
1913. Pitt, Septimus A., Central Public Library, Coventry, Librarian.
1902. Pittard, Jno., West Ham Chemical Works, West Ham, E., Chemical Manufacturer.
1884. Pittuck, F. W., 19, Stratford Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.
1909. Piutti, Prof. Dr. Arnaldo, Instituto Chimico-farmaceutico, R. Universita, Napoli, Italy, Director.
1899. Pizey, Jas. H., c/o S. Pearson and Son, The Refinery, Minatitlan, Vera Cruz, Mexico, Chemist.
1894. Platten, Frank, c/o Elliot's Metal Co., Selly Oak Works, near Birmingham, Metallurgical Chemist.
1890. Platts, Jno. C., "Sandygate," Chapel Lane, Wilmslow, Cheshire, Metallurgical Chemist.
1896. Plaut, Albert, P.O. Box 380, New York City, U.S.A., Wholesale Druggist.
1888. Playfair, David J., 7, Victoria Crescent, Dowanhill, Glasgow, Manufacturing Chemist.
1914. Plews, George, jun., c/o Braden Copper Co., Molino, Rancagua, Chile, Chemist.
1907. Poetschke, Paul, c/o L. D. Caulk Co., Milford, Del., U.S.A., Chemist.
1901. Pollard, Wm., Oakfield, Hitchin, Herts, Chemist (H.M. Geological Survey).
1904. Pollitt, Dr. Geo. P., 4, Whitehall Court, London, S.W., Chemist.
1902. Pollitt, Jas. C. T., 7, Grosvenor Road, Handsworth, Birmingham, Managing Chemist.
1883. Pollock, A., Kirkland, Bonhill, Dumbartonshire, Dyeworks Manager.
1890. Pomeroy, Dr. Chas. T., Bramhall Road, Rahway, N.J., U.S.A., Ink Manufacturer.
1909. Pond, Dr. Francis J., Stevens Institute of Technology, Hoboken, N.J., U.S.A., Professor of Chemistry.
1896. Pond, Prof. G. G., State College, Centre Co., Pa., U.S.A., Professor of Chemistry.
O.M. Pond, J. A., 99, Queen Street, Auckland, New Zealand, Analytical Chemist.
1906. Pont, A. Felix du, Box 31, Wilmington, Del., U.S.A., Explosives Manufacturer.
1895. Pont, Pierre S. du, c/o Dr. C. L. Reese, E.I. du Pont de Nemours Powder Co., Wilmington, Del., U.S.A., Explosives Manufacturer.
1912. Pope, Chester H., 39, Waldemar Avenue, Winthrop, Mass., U.S.A., Ink Manufacturer.
O.M. Pope, S., 34, Clarendon Road West, Chorlton-cum-Hardy, Manchester, Chemical Works Manager.
1899. Pope, Thos. H., The University, Edmund Street, Birmingham, Chemist and Lecturer on Brewing.
1900. Pope, Prof. W. J., F.R.S., University Chemical Laboratory, and (Journals) Holmesdale, Brooklanda Avenue, Cambridge, Professor of Chemistry.
1912. Porritt, B. D., c/o North British Rubber Co., Ltd., Castle Mills, Edinburgh, Chief Chemist.
1911. Porteous, Jas. W., c/o Bolckow, Vaughan, and Co., Ltd., Grange Hill, Bishop Auckland, Co. Durham, Chemist and Coke Oven Manager.
1902. Porter, J. Edw., P.O. Box 785, Syracuse, N.Y., U.S.A., Chemist.
1901. Porter, Jno. L., 8401, Panola Street, New Orleans, La., U.S.A., Chemist.
1884. Potter, Chas. E., Love Lane Sugar Refinery, Liverpool, Sugar Works Chemist.
1888. Potter, Chas. J., Heaton Hall, Newcastle-on-Tyne, Cement Manufacturer.
O.M. Potter, E. P., Chemical Works, Little Lever, near Bolton, Alkali Manufacturer.
1900. Potts, Geo. E., 200, Fifth Avenue, New York City, U.S.A., Explosives Manufacturer.
1910. Potts, Harold E., 66, Leasowe Road, Wallasey, Cheshire, Research Chemist.
1900. Powell, Harry J., 125, Thurlow Park Road, Dulwich, S.E., Glass Manufacturer.
1897. Power, Dr. Fred. B., Wellcome Research Laboratories, 6, King Street, Snow Hill, London, E.C., Director.
1907. Powers, Wm. A., c/o A. T. and S. F. R. R. Co., Topeka, Kans., U.S.A., Chief Chemist.
1902. Powney, Wm. E. F., 35, Priory Avenue, Hornsey, N., Analytical Chemist.
1912. Prasad, Prof. H., Government College, Ajmer, India, Professor of Science.
1897. Prentice, Dr. Bertram, Royal Technical Institute, Salford, Lecturer on Chemistry.
1902. Prentice, Dr. David, The Nook, Whitefield Road, Stockton Heath, Warrington, Chemist.
1903. Prentice, Jas., Cossipore Sugar Works, Cossipore, Calcutta, India, Chemist.
1911. Prescott, Alfred, 63, Corporation Street, Manchester, Chemical Agent.
1900. Prescott, Prof. Saml. C., 585, Boylston Street, Boston, Mass., U.S.A., Prof. of Ind. Biology.
1905. Preston, Jas. F., 403, Andover Street, Lowell, Mass., U.S.A., Manufacturing Chemist.
O.M. Price, Arthur F., 2503, Broadway, San Francisco, Cal., U.S.A., Analytical Chemist.
1905. Price, Dr. T. Slater, The Technical School, Birmingham, Lecturer on Chemistry.
1904. Prichard, Norman B., 40, Quebec Street, Sherbrooke, Quebec, Canada, Superintendent.
1905. Priest, Geo. Wesley, Beaver Leather Manufacturing Co., 28, Ferdon Street, Newark, N.J., U.S.A., General Manager.
1899. Prinsen-Geerligs, H. C., Wanningstraat 17, Amsterdam, Holland, Director of Sugar Cane Experimental Station.
1912. Pritchard, Thos. W., Wilmington, N.C., U.S.A., Wood Distiller.
1912. Prittie, Frank H., Southern Pacific Railway Laboratory, Sacramento, Cal., U.S.A., Assistant Chemist.
1896. Prochazka, Dr. Geo. A., c/o Central Dyestuff and Chemical Co., Newark, N.J., U.S.A., Colour Manufacturer.

O.M. Procter, Prof. H. R., The University, Leeds; and (Journals) Rowangarth, Ben Rhydding, near Leeds. Lecturer on Tanning.
1884. Procter, J. W., Skeldergate Bridge, York, Manure Manufacturer.
1890. Proctor, Miss Anne J., Free Library, Widnes, Librarian.
O.M. Proctor, C., 118, Grosvenor Road, London, S.W., Analytical Chemist.
1901. Propach, C., 146, West Kinzie Street, Chicago, Ill., U.S.A., Colour Merchant.
1912. Propach, Dr. Wilhelm, Dynamit Act.-Ges. vorm. A. Nobel und Co., Alsterdamer 391, Hamburg, Germany, Chemist.
1913. Prosser, Richard, 4478, St. Catherine W., Westmount, Que., Canada, Chemical Agent.
1906. Pudney, S. H., 156, Bellwood Avenue, Toronto, Canada, Chemist.
1905. Pugh, John V., Guiting House, Allesley, near Coventry, Works Director (Rudge-Whitworth, Ltd.).
1899. Pullar, Edmund, Keirfield, Bridge of Allan, Scotland, Manufacturer.
O.M. Pullar, R. D., Pullar's Dyeworks, Perth, Scotland, Dyer.
1913. Pulsifer, Lanson V., c/o Messrs. Valentine and Co., 364, Manhattan Avenue, Brooklyn, N.Y., U.S.A., Chemist.
1902. Puntan, H. H. C., 10, London Chambers, Durban, Natal, Public Analyst.
1894. Purdie, Dr. Thos., F.R.S., 14, South Street, St. Andrews, Professor of Chemistry.
1913. Purves, G. Thomson, Coke Ovens Dept., Auchengeich Colliery, Chryston, Scotland, Manager.
1905. Pyman, Dr. Frank Lee, "Sedgley," Selborne Road, Sidcup, Kent, Chemist.

Q

1903. Queeny, Jno. F., Monsanto Chemical Works, 1800, South 2nd Street, St. Louis, Mo., U.S.A., Chemical Manufacturer.
1903. Queneau, Augustin L. J., Jemeppe sur Meuse, Belgium, Metallurgical Engineer.
1887. Quibell, Oliver, Shalem Lodge, Newark-on-Trent, Manure Manufacturer.
1902. Quinan, Kenneth B., Cape Explosives Works, Somerset West, C.C., South Africa, and (subscriptions) c/o Cape Explosives Works, Ltd., 15, St. Swithin's Lane, E.C., Superintendent.

R

1911. Race, Joseph, City Hall, Ottawa, Canada, City Bacteriologist.
1904. Rademacher, Dr. Ferdinand, Prag-Carolinenthal, Austria, Chemical Manufacturer.
1900. Radley, Ernest G., 49, Ernest Street, West Norwood, S.E.
1902. Ramsay, A. Alexander, Laboratory, Department of Agriculture, 136, George Street, Sydney, N.S.W., Australia, Assistant Chemist.
O.M. Ramsay, Sir William, K.C.B., F.R.S., University College, London, W.C.; Journals to 19, Chester Terrace, N.W., Professor of Chemistry.
1885. Ramsay, W., c/o Cammell, Laird, and Co., Ltd., Birkenhead Ironworks, Birkenhead, Chemist and Assayer.
1911. Ramsay, Wm. G., Research Chemist.
1913. Ramsbottom, Dr. J. E., 98, Peabody Road, South Farnborough, Hants, Chemist.
1906. Ranck, Samuel H., Ryerson Public Library Building, Grand Rapids, Mich., U.S.A., Librarian.
1909. Randall, George, Severn Bank Tannery, Worcester, Tanner.
1910. Ranken, Charles, 19, Stockton Road, Sunderland, Analytical and Consulting Chemist.
1901. Ransom, Francis, The Chilterns, Hitchin, Herts, Manufacturing Pharmaceutical Chemist.
1905. Ransom, H. B., St. Stephen's House, Victoria Embankment, Westminster, S.W., Consulting Engineer.
1910. Ransome, A. Oswald, Beechwood, Greenock Road, Paisley, and (Journals) Warton, Carnforth, Lancashire, Works Chemist.
1898. Raschen, Dr. Julius, The Highlands, Runcorn, Cheshire, Consulting Chemist (United Alkali Co.).
1905. Raschig, Dr. F., Ludwigshafen a/Rhein, Germany, Manufacturing Chemist.
1908. Rassow, Prof. Dr. Berthold, Stephanstrasse 8, Leipzig, Germany, General Secretary, Vereins Deutscher Chemiker.
1893. Ratcliff, Frank D., Stourbank House, Stourport, Vinegar Brewer.
1904. Ratcliffe, C. F., Haigh Park Chemical Works, Stourton, near Leeds, Tar Distiller.
1914. Ratcliffe, Henry, Leeds Phosphate Works, Ltd., Midland Road, Hunslet, Leeds, Technical Chemist.
1898. Ratcliffe, Walter, 21, Mawdsley Street, Bolton, Analytical Chemist.
1901. Rawlins, Herbert J. L., The Cottage, Rainhill, Lancashire, Managing Director.
1903. Rawolle, Frederick C., c/o Marx and Rawolle, 100, William Street, New York City, U.S.A., Chemist.
O.M. Rawson, Chris., 22, Cumberland Street, Manchester, Consulting Chemist.
1909. Rawson, H. Wyatt, c/o Chartered Bank of India, Taiping, Perak, Fed. Malay States.
1909. Rayner, Arthur B., Normanhurst, Alexandra Park Road, Muswell Hill, N., Chemical Broker.
1912. Rayner, Edgar A., 71, Welldon Crescent, Harrow-on-the-Hill, Analytical Chemist.
1895. Read, E. J., c/o Pretoria Portland Cement Co., Ltd., P.O. Box 405, Pretoria, South Africa, Analyst.
1913. Read, Dr. John, University Chemical Laboratory, Cambridge, Assistant to Prof. of Chemistry.
1890. Reade, Thos., Sebright House, Tettenhall Wood, Wolverhampton, Manufacturing Chemist.
1908. Reavell, J. Arthur, 37, Parliament Street, Westminster, S.W., Engineer.
1912. Reddie, J. A., Sewage Disposal Works, Halifax, Yorks, Chemist.
1902. Redfern, C. G., 15, South Street, Finsbury, London, E.C., Patent Agent.
O.M. Redwood, Sir Boverton, Bart., 4, Bishopsgate, London, E.C., Petroleum Expert.
1887. Redwood, Robt., 4, Bishopsgate, London, E.C., Secretary.
1886. Rée, Dr. A., 15, Mauldeth Road, Withington, Manchester, Aniline Dye Manufacturer.
1902. Reed, Herbert C., 227-229, Fulton Street, New York City, U.S.A., Cons. Tanning Chemist.
1906. Reed, William, Works Manager.
1893. Reekie, J. A., Buckton Grange, Stalybridge, Calico Printer's Colour Mixer.
1883. Reeks, T. H., 106, Queen Victoria Street, London, E.C., Analytical and Consulting Chemist.
1897. Rees, W. H., El Dorado Oil Works, West Berkeley, Cal., U.S.A., Chemist.
1906. Rees, Walter J., 36, Holly Lane, West Smethwick, near Birmingham, Glass Works Chemist.
1900. Reese, Dr. Chas. L., Eastern Laboratory, P.O. Box 424, Chester, Pa., U.S.A., Chemist.
1913. Regan, Colston J., 14, Penerley Road, Catford, S.E., Analytical Chemist.
1897. Reid, Andrew, c/o L. and J. McLellan, 65, Port Dundas Road, Glasgow, Chemist.
1909. Reid, David E., Kodak Park, Rochester, N.Y., U.S.A., Chemist.
1906. Reid, James, Caldercruix Mills, by Airdrie, Scotland, Chemist.
1913. Reid, J. Meston, Vernon Lodge, Gateacre, Liverpool, Manufacturing Chemist.
1905. Reid, Dr. John H., Cranford, Barton Heys Road, Formby, Lancs, Chemist.
1907. Reid, Robert, Agencia de Tharsis, Huelva, Spain, Analytical Chemist.
1896. Reid, Robt., Oil Mills, Horbury Bridge, near Wakefield, Chemist.
O.M. Reid, Walter F., Fieldside, Addlestone, Surrey, Technical Chemist.

1893. Reid, Wm., jun., Bombay Dyeworks, Dadur, Bombay, India. Dyer.
1904. Reinherz, Otto, 3, Selborne Villas, Manningham, Bradford, Yorks, Chemist.
1906. Reinhold, Gustave, 26, Kidbrook Park Road, Blackheath, S.E., Works Manager.
1910. Reiter, Dr. Kaspar, Bayrischzell, Hochkreut, Bavaria, Chemist.
1898. Reitmeyer, Robt. E. D., 63, Crutched Friars, London, E.C., Chemical Merchant.
1904. Remington, Prof. Joseph P., 1832, Pine Street, Philadelphia, Pa., U.S.A., Author, U.S. Pharmacopœia.
1900. Remington, J. Stewart, Aynsome, Grange-over-Sands, R.S.O., Lancs, Consulting Chemist.
1903. Remsen, Professor Ira, Johns Hopkins University, Baltimore, Md., U.S.A., Professor of Chemistry.
1911. Renaud, Paul, 8, Rue Nouvelle, Paris (9^e), France, Consulting Engineer.
O.M. Rennie, Dr. E. H., University of Adelaide, South Australia, Professor of Chemistry.
1911. Rentschler, Mahlon J., c/o Oakland Chemical Co., Rossville, Staten Is., N.Y., U.S.A., Bacteriologist.
1901. Renwick, Frank F., Sunny Side, Weald Road, Brentwood, Essex, Chemist (Photographic Works).
1907. Reoch, Robert A. S., Pacific Mills Printworks, Laurence, Mass., U.S.A., Printworks Superintendent.
1894. Rettie, Theodore, 10, Doune Terrace, Edinburgh, Metallurgical Chemist.
1895. Reubens, Chas. M., 68, Cliff Street, New York City, U.S.A., Chemist.
1912. Reuter, Dr. L., Glycerin Manufacturer.
1905. Revis, Cecil, 5, Carlton Villas, Station Road, Barnes, S.W., Analyst.
O.M. Reynolds, Dr. J. Emerson, F.R.S., 3, Inverness Gardens, Kensington, W., Professor of Chemistry.
1912. Reynolds, Wm. Colebrook, "Wharfdale," Upminster, Essex, Manufacturing Chemist.
1913. Rhead, T. F. Eric, Home Office Experimental Station, Eskmeals, Cumberland, Research Chemist.
1908. Rhoads, J. Edgar, 2211, Shallcross Avenue, Wilmington, Del., U.S.A., Leather Chemist.
O.M. Rhodes, E., c/o Thos. Vickers and Sons, Widnes, Technical Chemist.
1892. Rhodes, P. J., Bridge House, Church, Accrington, Dye and Print Works Manager.
1889. Richards, Edgar, 60, Ayrault Street, Newport, R.I., U.S.A., Analytical Chemist.
1888. Richardson, Dr. Clifford, Room 1615, Woolworth Building, 233, Broadway, New York City, U.S.A., Chemical Engineer.
1903. Richardson, F. J., Chemical Works, Ringsend Docks, Dublin, Ireland, Chemical Manure Manufacturer.
1884. Richardson, F. W., County Analyst's Office, Bradford, Yorkshire, Analytical Chemist.
1900. Richardson, Jno. H., 57, Cavendish Drive, Rock Ferry, Cheshire, Manager.
1905. Richardson, L. G., 66, Bishopgate Street, Norwich, Chemist.
1891. Richardson, Walter W., Aldingham, Park View Crescent, Roundhay, Leeds, Manufacturing Chemist.
1903. Richardson, Wm., Linfield, Wood Lane, Headingley, Leeds, Drysalter.
1894. Richardson, Wm. H., Newsky Thread Mills, Malaja, Bolotnaja, St. Petersburg, Russia, Textile Chemist.
1898. Richmond, Jno. R., The Hollies, Blurton, Longton, Staffs, Alkali Works Manager.
1901. Richmond, Sylvester O., Royal William Yard, Plymouth, Analytical Chemist.
1884. Rideal, Dr. Samuel, Laboratory, 28, Victoria Street, Westminster, S.W., Consulting Chemist.
1905. Ridge, H. M., 62, London Wall, London E.C., Mining Engineer.
O.M. Ridsdale, C. H., Laboratory, 3, Wilson Street, Middlesbrough, Analytical Chemist.
1899. Riederer, Emil J., Foreite Works, Landing, N.J. U.S.A., Works Chemist.
1902. Riederer, Dr. Herman S., 160, Clifford Street, Newark, N.J., U.S.A., Chemist.
1907. Rigg, Gilbert, c/o New Jersey Zinc Co., Palmerton, Carbon Co., Pa., U.S.A., Chemist.
1892. Riker, Jno. J., 19, Cedar Street, New York City, U.S.A., Merchant.
O.M. Riley, E., 2, City Road, Finsbury Square, London, E.C., Metallurgical Chemist.
1913. Riley, George, Etna Works, South Lambeth Road, London, S.W., Chemical Engineer.
1905. Riley, Louis J., 8, Newton Road, London, W., Chemist.
1912. Riley, Walter A., 100, King Street, Norwich, Brewer.
1899. Rink, Arnold, 11, Bridgewater Street, Barbican, London, E.C., Tannin Extract Manufacturer.
1889. Rintoul, Wm., "Lauriston," Ardrossan, Ayrshire, Explosives Chemist.
1901. Ripley, Philip F., 7, Abbott Street, Andover, Mass., U.S.A., Chemist.
1907. Roberts, Chester, Swarthmore College, Swarthmore, Pa., U.S.A., Superintendent.
O.M. Roberts, F. G. Adair, Oak Hill Lodge, Hampstead, N.W., and Jnls. to H. Shankster, 57, Balfour Road, Ilford, Chemical Manufacturer.
1901. Roberts, H. E. U., c/o British Explosives Synd., Pitsea, Essex, Chemist.
1911. Roberts, H. W., Dynamite Factory, Somerset West, Cape Province, South Africa, Chemist.
1902. Roberts, Wm. H., City Analyst's Office, Ashton Street, Liverpool, Analytical Chemist.
1891. Robertson, Alex. A., Riversdale, Cressington Park, Liverpool, Technical Chemist.
1897. Robertson, Andrew J., 2, North Ninth Street, Richmond, Va., U.S.A., Analytical Chemist.
1910. Robertson, Charles, c/o Messrs. S. Allsopp and Sons, Ltd., Burton-on-Trent, Brewer.
1900. Robertson, Jas., Barncraig, South Medrox, by Glenboig, Analytical Chemist.
1910. Robertson, Dr. Joseph G., Braidwood, Tollcross, Glasgow, Manufacturer.
1891. Robertson, Dr. Robt., Research Dept., Royal Arsenal, Woolwich; and (Journals) 29, Charlton Road, Blackheath, S.E., Research Chemist.
1910. Robertson, William, Chemical Dept., City and Guilds College, Exhibition Road, London, S.W., Lecturer and Research Chemist.
1913. Robins, Edmund A., c/o Messrs. Kodak, Ltd., Wealdstone, Middlesex, Assistant Works Manager.
1913. Robinson, C. Stanley, 86, Edgbaston Road, Smethwick, Birmingham, Works Chemist.
1897. Robinson, Clarence J., 708, Jewett Avenue, West New Brighton, N.Y., U.S.A., Chemist.
1902. Robinson, Hy. Fishwick, Culcheth Chemical Works, Newton Heath, Manchester, Manufacturing Chemist.
O.M. Robinson, H. H., 42, Penywern Road, Earl's Court, S.W., Analytical Chemist.
1907. Robinson, Herbert W., Robinson Bros., Ltd., Ryders Green, West Bromwich, Staffordshire, Tar Distiller.
1911. Robinson, Jas. H., 11, East Street, Rugby, Analytical Chemist.
O.M. Robinson, Jos., Farnworth, Widnes, Chemical Manufacturer.
1887. Robinson, Thomas, (Journals) 401, West Street, Glasgow: and (communications), The Villa, Nitshill, Chemical Works Manager.
1902. Robitschek, Carl, 200, Worth Street, New York City, U.S.A., Scientific Brewer.
1884. Rodger, Edw., 1, Clairmont Gardens, Glasgow, W.
1904. Rodger, Robert, Government Laboratory, Clement's Inn Passage, Strand, London, W.C., Chemist.
1905. Rodger, R. L., The Peña Copper Mines, Ltd., 736, Salisbury House, London Wall, E.C., Manager.
1909. Rody, Franz A., 258, Van Buren Street, Newark, N.J., U.S.A., Chemist.

1903. Roelofsen, Dr. J. A., c/o Coal Distillation Co., Middlesbrough, Yorks, Works Manager.
1910. Roessler, Dr. F., 89, High Street, Perth Amboy, N.J., U.S.A., Chemist.
1905. Rogers, Dr. Allen, Pratt Institute, Brooklyn, N.Y., U.S.A., Research Chemist.
1900. Rogers, Geo. J., 32, Chudleigh Road, Brockley, S.E., Chemist.
1908. Rogers, Harry V., Ash Street, Ilkeston, Derbyshire, Engineer.
1907. Rogers, Henry L., Casilla 1118, Buenos Aires, Argentina, Analytical Chemist.
1909. Rogers, Herbert, 52, Cannon Street, London, E.C., Rubber Works Chemist.
1899. Rogers, John, c/o Nobel's Explosives Co., Ltd., Nobel House, Glasgow, Chemist.
1910. Rogers, L. Joslyn, Chemical and Mining Building, The University, College Street, Toronto, Canada.
1911. Röhm, Dr. Otto, Weiterstädterstrasse 4/6, Darmstadt, Germany, Chemist.
1898. Roller, H. C., 493, Central Avenue, Newark, N.J., U.S.A., Superintendent.
1899. Rollin, Chas., Bylton, East Jarrow-on-Tyne, Chemical Manufacturer.
1909. Rollin, Hugh, Overdene, Riding Mill-on-Tyne, Chemical Manufacturer.
O.M. Rollin, J. C., 1, St. Nicholas Buildings, Newcastle-on-Tyne, Chemical Manufacturer.
1907. Rolph, George M., c/o California and Hawaiian Sugar Refining Co., Crockett, Cal., U.S.A., Sugar Refiner.
1905. Romanes, J. W., c/o Brotherton and Co., Ltd., Litherland, Liverpool, Chemical Engineer.
O.M. Roscoe, Rt. Hon. Sir Henry, F.R.S., 10, Bramham Gardens, South Kensington, S.W., Consulting Chemist.
1904. Rose, Jno., Wicken House, Stretton, near Warrington, Technical Chemist.
1901. Rose, Jno. Leonard, 3, Florence Road, Ealing, W., Chemist.
1902. Rosebrugh, Prof. T. R., 2425 South State Street, Syracuse, N.Y., U.S.A., Professor of Electrical Engineering.
1897. Rosengarten, Dr. Geo. D., P.O. Box 1625, Philadelphia, Pa., U.S.A., Manufacturing Chemist.
1913. Rosenplaenter, Carlos B., 2, Elmbourne Road, Upper Tooting, S.W., Petroleum Technologist.
1893. Ross, Arthur, 1, Glengall Road, Old Kent Road, London, S.E., Analytical Chemist.
1900. Ross, Raymond, Public Analyst's Office, Burnley, Lancashire, Analytical Chemist.
1910. Ross, Thos. M., c/o Burmah Oil Co., Ltd., P.O. Box 67, Rangoon, Burmah, Analytical Chemist.
1911. Ross, Prof. W. J. Clunies, 12, Church Street, Ashfield, Sydney, N.S.W., Australia, Prof. of Chemistry (Sydney Technical College).
1910. Rossati, Guido, 226, Lafayette Street, New York City, U.S.A., Agricultural Chemist.
1911. Rossi, Dr. Carlo, 29, Via Leopardi, Milano, Italy, Electro-chemist.
1906. Rossi, Louis M., c/o General Bakelite Co., Perth Amboy, N.J., U.S.A., Works Manager.
1913. Rossini, Jas. L., c/o New Oil Refining Process, Ltd., Bradfield Road, Silvertown, E., Oil Works Manager.
1906. Rossiter, E. C., Brougham, West Hagley, Worcestershire, Chemical Engineer.
1888. Rothwell, C. F. Seymour, Photographic Works, Mobberley, Cheshire, Chemist.
O.M. Rottenburg, Dr. Paul, 55, West Regent Street, Glasgow, Chemical Merchant.
1903. Rouse, Wm., Woodburn, Arthurlie Street, Barrhead by Glasgow, Chemist.
1906. Rowell, Herbert W., 36, Thornbury Road, Osterley Park, W., Analytical Chemist.
O.M. Rowland, W. L., 4800, Chester Avenue, Philadelphia, Pa., U.S.A., Chemist.
1904. Rowley, Ernest W., Chemical Laboratory, C.M.E. Department, North Eastern Railway, Darlington, Analytical Chemist.
1908. Rowley, Frank, 4, Doughty Street, London, W.C., Metallurgist.
1913. Rowley, Henry, 41, Barrack Street, Perth, Western Australia, Analyst.
1901. Rowley, Walter Eugene, c/o National Aniline and Chemical Co., 100, William Street, New York City, U.S.A., Chemist.
1904. Rowling, S. R., 1, Beechwood, Kendal, Westmoreland, Chemist.
1913. Rowse, Walter W., 39, Oliver Street, Boston, Mass., U.S.A., Representative of Cassella Color Co.
1896. Royal-Dawson, H., 5, University Road, Galway, Ireland, Chemist.
1898. Royle, Chas. L., c/o Cartavio Sugar Co., Trujillo, Peru, Sugar Chemist.
O.M. Royse, Sir Samuel W., St. Andrew's Chambers, 20, Albert Square, Manchester, Chemical Engineer.
1913. Rubinstein, I. H., 164, Cheetham Hill Road, Manchester, Technical Chemist.
1902. Rücker, Dr. Hermann von, 91, Lancaster Avenue, Buffalo, N.Y., U.S.A., Chemist.
1896. Ruddock, Fred. G., Corporation Street, Warrington, Analytical Chemist.
1895. Rudge, Alfred, Sutton Alkali Works, St. Helens, Lancs, Analytical Chemist.
1911. Rudnick, Paul, c/o Armour and Co., Union Stock Yards, Chicago, Ill., U.S.A., Chemist.
1908. Rudolf, Prof. Norman S., Dept. of Applied Chemistry, Indian Institute of Science, Bangalore, India, Professor.
1909. Rudorf, Dr. G., 52, Cranley Gardens, Muswell Hill, N., Manufacturing Chemist.
1884. Ruffle, Jno., Musley, Ware, Herts, Consulting Chemist and Electrician.
1905. Rüger, Richard, 389, New Chester Road, Rock Ferry, Cheshire, Chemist.
1898. Ruhl, Louis, c/o Roessler and Hasslacher Chemical Co., 100, William Street, New York City, U.S.A., Chemical Merchant.
1909. Ruiloba, J. A., c/o U.S. Steel Corporation, 71, Broadway, New York City, U.S.A., Engineer.
1910. Rule, Dr. Alexander, The University, Liverpool, Lecturer in Chemistry.
O.M. Rumble, C., 169, Gleneldon Road, Streatham, S.W., Chemist.
1899. Rumbold, Wm. R., Calverley Lodge, Tunbridge Wells, Kent, Electro-Metallurgist.
1913. Rumi, Dr. Tomás J., Calle Saenz-Peña No. 722, Buenos Aires, Argentina, Doctor of Chemistry.
1911. Runeckles, A. R., c/o Brotherton and Co., Ltd., Litherland Tar Works, Liverpool, Technical Chemist.
1903. Runyan, Elmer G., Hutchins Building, Washington, D.C., U.S.A., Chemist and Gas Inspector.
1899. Rushby, Wm., Oak View, Batley, Yorks, Analyst.
1906. Russell, David, Rothes, Markinch, Fife, Scotland, Paper Maker.
1912. Russell, George H., c/o Michaelis, Hallenstein, and Co. Propy., Ltd., Footscray, Vic., Australia, Leather Trades Chemist.
1913. Russell, Stanley, Seifenfabrik Sunlight, Olten Switzerland, Works Manager.
1912. Russell, Thomas F., 131, Steade Road, Sheffield, Analytical Chemist.
1910. Russell, William, 146, Peel House Lane, Widnes, Lancashire, Chemist.
1905. Ruttan, Prof. R. F., Medical Faculty, McGill University, Montreal, Canada, Professor of Chemistry.
1909. Ryall, W. E., c/o North-West Soap Co., 63, Garden Reach, Calcutta, India, Soapworks Chemist.
1905. Ryan, Prof. F. G., c/o Parke, Davis, and Co., Detroit, Mich, U.S.A., Manufacturing Chemist.

S

1895. Saalfeld, Adolphe, 2, South King Street, Manchester, Chemical Merchant.
1895. Saarbach, Dr. L., 114, Pearl Street, New York City, U.S.A., Consulting Chemist.

1905. Sabio, Alvah H., 432, Sandford Avenue, Flushing, N.Y., U.S.A., Chemist, Varnish Works.
1883. Sadler, A. E., Sand Hall, Ulverston, Lancashire, Manufacturing Chemist.
1884. Sadtler, Dr. S. P., 145, North 10th Street, Philadelphia, Pa., U.S.A., Consulting Chemist.
1896. Sadtler, Dr. S. S., c/o Samuel P. Sadtler and Son, 39, South 10th Street, Philadelphia, Pa., U.S.A., Analytical and Consulting Chemist.
1897. Sage, C. Edward, 10, London Street, London, E.C., Consulting Chemist.
1902. Sahm, Louis N., c/o The Heller and Merz Co., 505, Hudson Street, New York City, U.S.A., Chemist.
1884. Salamon, A. Gordon, 1, Fenchurch Avenue, London, E.C., Consulting Chemist.
1885. Salamon, Jno., Ferry Road, Rainham, S.O., Essex, Manufacturing Chemist.
1911. Salamon, Maurice S., 79, Mark Lane, London, E.C., Consulting Analyst.
1884. Salis-Mayenfeld, Dr. E. von, 24, South Allen Street, Albany, N.Y., U.S.A., Technical Chemist.
1907. Samuel, Marcus R. A., c/o Compania General de Tabacos Filipinas, 37, Fenchurch Street, London, E.C., Merchant.
O.M. Samuel, W. Cobden, 66, Croxted Road, West Dulwich, S.E., Analytical Chemist.
1896. Samuelson, Francis A. E., Sir B. Samuelson and Co., Ltd., Middlesbrough, Ironmaster.
1904. Sand, Dr. Henry J. S., University College, Nottingham, Lecturer and Demonstrator.
1910. Sandeman, Archibald, Ruchill Oil Works, Glasgow, Chemist.
1906. Sanders, J. McConnell, Struan, Beaconsfield Road, Blackheath, S.E., Analytical and Consulting Chemist.
1895. Sanderson, John, c/o B. S. Cohen, Ltd., Neasden Lane, London, N.W., Chemist.
1907. Sandig, A., P.O. Box 702, Chicago, Ill., U.S.A., Sales Manager.
1890. Saniter E. H., Strafford Villa, Moorgate, Rotherham, Analytical Chemist.
1913. Saravi, Dr. Alberto, Calle Libertad 86, Paraná, Entre-Rios, Argentina, Professor of Chemistry.
1901. Sargent, Dr. Geo. W., c/o Crucible Steel Co. of America, Oliver Building, Pittsburgh, Pa., U.S.A., Chemist and Metallurgist.
1910. Sargent, R. N., c/o Roessler and Hasslacher Chem. Co., Perth Amboy, N.J., U.S.A., Chemical Engineer.
1911. Sauer, J., 121, Van Breestraat, Amsterdam, Holland, Sugar Chemist.
1910. Sauerschnig, José, P.O. Box 313, Mexico City, Mexico, Acid Manufacturer.
1903. Saunders, Lewis E., 123, Buffalo Avenue, Niagara Falls, N.Y., U.S.A., Electro-Chemical Engineer.
1896. Saunders, Walter M., 20, Dewey Street, Olneyville, R.I., U.S.A., Analytical Chemist.
1911. Saville, W. B., 5, Howard Street, Horton Lane, Bradford, Yorks, Analytical Chemist.
1895. Sawers, Wm. D., 7, Minard Road, Partick Hill, Glasgow, Chemist.
1907. Saxe, Joel B., P.O. Box 1086, Montreal, Canada, Chemist.
1898. Saxe, Sigmond, 107, Manhattan Avenue, New York City, U.S.A., Manufacturing Chemist.
1890. Sayers, Jos. J., Nobel Villa, Stevenston, Ayrshire, Explosives Chemist.
1913. Scarfe, H. Crespin, "Chikatoo," Willifield Way, Hendon, N.W., Public Officer.
1899. Schaak, Dr. Milton J., 108, Penn Street, Brooklyn, N.Y., U.S.A., Chemist.
O.M. Schack-Sommer, Dr. G., 87, Victoria Street, London, S.W., Sugar Refiner.
1908. Schad, Dr. Philip, The Gables, Hartford, Cheshire, Manufacturing Chemist.
1910. Schaefer, Dr. George L., New York Quinine and Chemical Works, 105, North 11th Street, Brooklyn, N.Y., U.S.A., Chemist and Technical Manager.
1903. Schanche, H. G., 3101, Gray's Ferry Road, Philadelphia, Pa., U.S.A., Chemist.
1912. Schapiro, Hugo H. B., Wadsworth, Ohio, U.S.A., Chemist.
1908. Schatzmann, Dr. Paul, Isleben bei Fluelen, Switzerland, Chemist.
1908. Scheele, Edward H., 3, Lloyds Avenue, London, E.C., Chemical Merchant.
1903. Scheidel, Dr. Aug., c/o Commonwealth Portland Cement Co., 4, O'Connell Street, Sydney, N.S.W., Australia, Managing Director.
1886. Schellhaas, Henry Alf., Thornhill, Beech Road, Hartford, Northwich, Mechanical Engineer.
1904. Schenck, Henry, c/o Merck and Co., Box 1443, New York City, U.S.A.
1894. Schidrowitz, Dr. P., 57, Chancery Lane, London, W.C., Research Chemist.
1905. Schill, Dr. Emil, 603, West 111th Street, New York City, U.S.A., Chemist.
1909. Schlagintweit, Theo., 94, Market Street, Manchester, Imperial German Consul.
1902. Schlegel, Jno. Wm., New York Sugar Refinery, Long Island City, N.Y., U.S.A., Chemist.
1893. Schleicher, Francis J., 38, West Tenth Street, Long Island City, N.Y., U.S.A., Technical Chemist.
1901. Schlichting, Emil, 38, Cranberry Street, Brooklyn, N.Y., U.S.A., Chemist.
1906. Schmidt, J., 52, Camberwell Green, London, S.E., Works Manager.
1907. Schmitt, Charles A., The Carter's Ink Co., Cambridge "C.," Boston, Mass., U.S.A., Chemist.
1906. Schneible, Joseph, 934-6, People's Gas Building, Chicago, Ill., U.S.A., Chemical Engineer.
1904 Schniewind, Heinrich, jun., Susquehanna Silk Mills, 18, West 18th Street, New York City, U.S.A., Vice-President and Treasurer.
1907. Schober, Prof. W. B., Lehigh University, South Bethlehem, Pa., U.S.A., Professor of Chemistry.
1904. Schoeller, Dr. Walter R., 10, Bedford Place, London, W.C., Metallurgical Research Chemist.
1902. Schofield, Prof. Jas. A., The University, Sydney, N.S.W., Australia, Lecturer in Chemistry.
1908. Scholefield, Fred., c/o Messrs. Burgess, Ledward, and Co., Ltd., Dyehouse Dept., Walkden, Manchester, Works Chemist.
O.M. Scholefield, H. E., Edge Hill Chemical Works, Liverpool, Chemical Manufacturer.
1906. Schroeder, C. M. E., Rutherford, N.J., U.S.A., Analytical Chemist.
1895. Schroeder, E. August, c/o Church and Dwight Co., 1416, Willis Avenue, Syracuse, N.Y., U.S.A., Chemist.
1908. Schüll, Gustav, Messrs. Carl Schleicher und Schüll, Düren, Rheinland, Germany, Filter Paper Manufacturer.
1906. Schulten, Dr. C., P.O. Box 279, Calcutta, India, Analytical Chemist.
1904. Schultz, Carl R., 440, First Avenue, New York City, U.S.A., Mineral Water Manufacturer.
1901. Schultze, Wm., c/o General Chemical Co., Laurel Hill, Long Island, N.Y., U.S.A., Chemist.
1893. Schüpphaus, Dr. R. C., 1466, Dean Street, Brooklyn, N.Y., U.S.A., Consulting Chemist.
1893. Schwab, Dr. L. C., Sedanstrasse 53, Bernburg, Anhalt, Germany, Technical Chemist.
1908. Schwalbe, Dr. Carl G., Neue Kreugstrasse 17, Eberswalde, bei Berlin, Germany, Professor (Kgl. Forstakademie).
1907. Schwamm, Chas. A., c/o Antoine Chiris, 20, Platt Street, New York City, U.S.A., Chemist.
1889. Schweich, Emile. *See* Mond, Emile S.
1894. Schweitzer, Dr. H., Riverside Mansions, corner 113th Street and Riverside Avenue, New York City, U.S.A., Chemical Expert.
1906. Schwenn, Lorenz R., c/o Casein Co. of America, Bainbridge, N.Y., U.S.A., Vice-President.
1906. Scott, Alex. C., 26, Prince's Square, Bayswater, London, W., Explosives Manufacturer.
1891. Scott, Andrew, Royal Gunpowder Factory, Waltham Abbey, Essex, Analytical Chemist.

1889. Scott, Ernest G., c/o Ernest Scott and Co., Ltd., Kingsway House, Kingsway, London, W.C., Chemical Engineer.

1912. Scott, Harold M., 32, Woodfield Road, Cheadle Hulme, Cheshire, Works Chemist.

1898. Scott, Jas., Cawnpore Woollen Mills, Cawnpore, India, Chemist.

1894. Scott, Jno. Gillespie, Annislea, Clermiston Road, Corstorphine, Edinburgh, Analytical Chemist.

1912. Scott, Jno. William, 576, Church Street, Toronto, Canada.

1913. Scott, Wm. Chas., c/o The Bay View Foundry Co., Sandusky, Ohio, U.S.A., Chemist.

1913. Scott, Wm. C., Bay View Foundry, Sandusky, Ohio, U.S.A., Chemist.

1907. Scott, Wm. F., c/o Madison Woollen Co., Madison, Maine, U.S.A., Manager.

1894. Scott-Smith, G. E., 67, Surrey Street, Sheffield, Analytical and Consulting Chemist.

1904. Scoville, Wilbur L., c/o Parke, Davis, and Co., Detroit, Mich., U.S.A., Analytical Chemist.

O.M. Scudder, F., Mersey and Irwell Joint Committee, 44, Mosley Street, Manchester, Chemist.

1889. Searl, Albert, Montreux, Victoria Road, Sidcup, Kent, and (Jnl.) 30, Cobham Road, Westcliff-on-Sea, Technical Chemist.

1898. Searle, Alfred B., The White Building, Fitzalan Street, Sheffield, Analytical Chemist.

1901. Sederholm, Erik, K. Flottans Varf, Stockholm, Sweden, Chemist (Royal Navy Board).

1905. Seeker, A. F., 160, Midwood Street, Brooklyn, N.Y., U.S.A., Food Analyst.

1907. Seelemann, Dr. A., c/o Sprengstoffwerke Dr. R. Nahnsen und Co., Mönckebergestrasse 31, Hamburg, Germany, Managing Director.

1907. Seidensticker, Lewis J., c/o Atlantic Sugar Refineries, Ltd., St. John, New Brunswick, Canada, Chief Chemist.

1896. Seldner, Rudolph, 383, St. John's Place, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.

1904. Seligman, Dr. Richard, Point Pleasant, Putney Bridge Road, Wandsworth, S.W., Chemist.

1908. Sellen, Elijah, Gasworks Laboratory, M.L.H. & P. Co., Elm Station, Montreal, Canada, Chemist.

1905. Sellers, Geo. E., Hopton Lane, Mirfield, near Huddersfield, Aniline Colour Maker.

1898. Sen (Gupta), Nagendra Nath, 18, Lower Chitpur Road, Calcutta, India, Physician and Chemist.

1910. Sen, Prof. Rajendra Nath, Engineering College, Sibpur, Bengal India, Professor of Tinctorial Chemistry.

1899. Senior, Francis L., Box 31, Sanford, Maine, U.S.A., Mill Chemist.

1906. Setz, C. F., Herculaneum, Mo., U.S.A., Chemist and Metallurgist.

1905. Sewell, B. F. Brooke, P.O. Box 70, Washington, D.C., U.S.A., Chemical Engineer.

1896. Seyler, Clarence A., Public Analysts' Office, Nelson Terrace, Swansea, Chemist and Assayer.

1907. Seymour, Tom G., Kilton, Northway, Wavertree, Liverpool, Analytical Chemist.

1911. Seymour-Jones, R. A., Oaklands, Hilltop, Latchford, Warrington, Research Chemist.

1903. Shacklady, T. G., Hope Point, Cliffe at Hoo, Kent, Technical Chemist.

1911. Shah, Prof. P. G., 759, Sankdi Sheri, Ahmedabad, India, Professor of Chemistry, Forman Christian College.

1906. Shah, Prof. S. J., Dhanasutar's Street, Ahmedabad, India, Consulting Chemist.

1905. Shainwald, R. L., jun., 100, William Street, New York City, U.S.A., Chemist.

1892. Shanks, Arch., 5, Green Lodge Terrace, Greenhead, Glasgow, Chemist.

1908. Shanks, John, Dalmeny Park, Barrhead, near Glasgow, Sanitary Engineer.

1904. Sharples, G. H., Newton Gardens, Middlewich, Cheshire, Works Chemist.

1905. Sharples, Philip P., 560, Concord Avenue, Belmont, Mass., U.S.A., President (Natl. Coal Tar Co.).

1884. Sharples, Stephen P., 22, Concord Avenue, Cambridge, Mass., U.S.A., Analytical Chemist.

1911. Sharrock, Charles W., Lion Works, West Thurrock, Grays, Essex, Cement Manufacturer.

1900. Sharwood, Dr. Wm. J., c/o Homestake Mining Co., Lead, South Dakota, U.S.A., Metallurgical Chemist.

1900. Shattuck, A. F., c/o Solvay Process Co., Detroit, Mich., U.S.A., Chemist.

1913. Shaw, T. W. A., "Springfield," Dee View Road, Heswall, Cheshire, Process Manager.

1912. Shaw, W. D. Hamilton, c/o Coppée Coke Oven Co., Ltd., King's House, Kingsway, London, W.C., Technical Chemist.

1912. Shearman, Cecil H., The Tees Bone Mill, Thornaby-on-Tees, Managing Director.

1904. Shedden, Frank, 25, Middleborough Road, Coventry, Science Master.

1903. Sheldon, Dr. N. L., Cordite Factory, Aruvankad, Nilgiri Hills, India, Works Manager.

1912. Shelley, F. F., Apothecaries Hall, Blackfriars, London, E.C., Analytical Chemist.

1912. Shelley, Wm. E., 20, Mount Street, Manchester, Engineer.

1911. Shelton, James, 44, Barclay Road, Fulham, S.W., Chemist.

1913. Shengle, J. C., c/o Major Bros., Ltd., Kiangsu Chemical Works, Shanghai, China, General Manager.

1892. Shenton, Jas. P., 37, Torbay Road, Chorlton-cum-Hardy, near Manchester, Analytical Chemist.

1889. Shepard, Dr. Chas. U., (communications) P.O. Box 42, Summerville, S.C.; and (Journals) P.O. Box 284, Charleston, S.C., U.S.A.

1906. Shepard, Jas. H., Experiment Station, Brookings, S. Dak., U.S.A., Agricultural Chemist.

1907. Shepheard, Fred. G., Kilbeg Cottage, Carrutherstown, Ruthwell, Dumfriesshire, Chemist.

1904. Shepherd, A. B., Copenhagen Oil Mills, Limehouse, London, E., Analytical Chemist.

1893. Shepherd, H. H. B., Crayside, Bexley, Kent, Chemist.

1898. Shepherd, Reginald des F., Central Laboratory, Rhodes, Manchester, Printworks Chemist.

1909. Shepherd, Stephen W., c/o Brotherton and Co., Ltd., Nechells Chemical Works, Birmingham, Works Manager.

1899. Shero, John E., c/o Aluminium Co. of America, Niagara Falls, N.Y., U.S.A., Chemist.

1893. Shields, Dr. John, Minas de Rio Tinto, Prov. de Huelva, Spain, Chemist.

1896. Shimomura, Prof. K., Shinkarasumaru Kojinguchi Sagaru, Kyoto, Japan, Professor of Chemistry.

1905. Shoffstall, Arthur S., 269, Second Street, New Brighton, Staten Is., N.Y., U.S.A., Chemist.

1899. Sholes, Chas. E., 80, Maiden Lane, New York City, U.S.A., Chemical Agent.

1900. Shonk, Albert, 10, Dartmouth Road, Hendon, N., Analytical Chemist.

1897. Shores, Dr. Jeff. H., 20, Saltwell View, Gateshead-on-Tyne, Chemist.

1904. Short, Andrew, 3, Prudhoe Terrace, Tynemouth, Northumberland, Works Chemist.

1902. Shoubridge, Sydney Y., M.I.C.E., Gasworks, Lower Sydenham, S.E., Gas Engineer.

1910. Shrimpton, Jno. K., Bound Brook, N.J., U.S.A., Works Manager.

1901. Shukoff, Dr. Alexis A., Borowaja No. 86, St. Petersburg, Russia, Technical Chemist.

1899. Shuler, Darius P., Fredericktown, Mo., U.S.A., Chemist.

1890. Shutt, Frank T., Central Experimental Farm, Ottawa, Canada, Agricultural Chemist.

1906. Shuttleworth, E. B., 220, Sherbourne Street, Toronto, Canada, Chemist.

1901. Siau, Raymond L., Springfield Brewery, Wolverhampton, Research Chemist.

1902. Sibley, Samuel E., Hawthorne, King Street, Randwick, Sydney, N.S.W., Australia, Technical Chemist.

1907. Siebel, Fred. P., 960-962, Montana Street, Chicago, Ill., U.S.A., Analytical Chemist.

1902. Siebold, Alfred, c/o Lactose Ltd. Hibernia Works, Tipperary, Ireland, Technical Chemist.
1901. Silberrad, Dr. Oswald, Sunny Croft, Buckhurst Hill, Essex, Research Chemist.
1912. Sillars, Daniel, The Laboratory, Bolckow, Vaughan, and Co., Ltd., South Bank, S.O., Yorks, Metallurgical Chemist.
1892. Silvester, Harry, 78, Holyhead Road, Handsworth, Birmingham, Analytical and Consulting Chemist.
1901. Sim, Wilfrid A., c/o Wm. Sim and Sons, 40, Jane Street, Leith, Scotland, Colour Manufacturer.
1912. Simmance, John F., 25A, Westminster Palace Gardens, Victoria Street, Westminster, S.W., Managing Director (Alexander Wright and Co.).
1911. Simmons, Thos. A., 298, Ditchling Road, Brighton, Analytical Chemist.
1903. Simmons, Wm. H., Oakleigh, Stoke Newington Common, N., Analytical Chemist.
1898. Simon, Dr. A., 80, Bishopsgate, London, E.C., Chemical Engineer.
1905. Simons, Albert J., Pontianak, Dutch West Borneo, viâ Singapore, S.S., Engineer.
1902. Simonson, Wm., 126, West 9th Street, Cincinnati, Ohio, U.S.A., Chemist.
1905. Simpson, Henry, 26, Austen Avenue, Sherwood Rise, Nottingham, Works Chemical Assistant.
O.M. Simpson, W. S., The Gables, Cannon Hill, Southgate, N., Analytical Chemist.
1900. Sims, W. Edgar, c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Assistant Manager.
1894. Sinclair, Dr. W., 250, Ferry Road, Leith, Scotland, Chemist.
1890. Sindall, R. W., 2, Oxford Court, Cannon Street, London, E.C., Paper Chemist.
1911. Singh, Shersingh W., N.W. Railway, Kasur, Punjab, India, Engineer.
1899. Singmaster, J. Arthur, c/o New Jersey Zinc Co. of Penna., Palmerton, Pa., U.S.A., Chemist.
1901. Sinnatt, Frank S., 321, Great Clowes Street, Higher Broughton, Manchester, Demonstrator of Chemistry.
1914. Sjödahl, H.A., c/o The Chatfield Manufacturing Co., Station P., Cincinnati, Ohio, U.S.A., Chemist.
1912. Skellon, Herbert, Helsby Cable Works, Helsby, near Warrington, Chemist.
1894. Skelton, John R., c/o Norwich Crape Co., Ltd., St. Augustine's, Norwich, Managing Director.
1897. Skertchly, W. P., Laboratory, 11, Billiter Square, London, E.C., Analytical Chemist.
1891. Skilton, C. F. E., c/o Beamish and Crawford, Ltd., Cork, Ireland, Brewer.
1901. Skinner, Hervey J., 71, West Chestnut Street, Wakefield, Mass., U.S.A., Chemist.
1908. Skinner, Wm., 38, Sauchiehall Street, Glasgow, Analytical Chemist.
1904. Skirrow, Dr. F. W., State University, Boulder, Colo., U.S.A., Research Chemist.
1911. Skjold, E., Elm View, The Avenue, Erith, Kent, Technical Manager and Chemist.
1904. Skowronski, S., c/o Raritan Copper Works, Perth Amboy, N.J., U.S.A., Chemist.
1891. Skurray, Thos., The Brewery, 40, Ock Street, Abingdon, Berks, Brewer.
1913. Slade, Dr. Roland E., University College, Gower Street, London, W.C., Lecturer in Physical Chemistry.
1904. Slator, Dr. Arthur, 174, Ashby Road, Burton-on-Trent, Lecturer and Demonstrator.
1912. Slattery, F. J., 42, Mathews Park Avenue, Stratford, E., Analytical Chemist.
1906. Sleeper, Robt. R., 112, Charles Street, Lowell, Mass., U.S.A., Instructor in Dyeing.
1895. Slocum, Dr. Frank L., 401, South Linden Avenue, E.E., Pittsburg, Pa., U.S.A., Chemist.
1913. Slusser, Holland B., 318, Sixth Street N.W., Canton, Ohio, U.S.A., Analytical Chemist.
1883. Smail, J. I., Warren Wood, Hayes Common, Beckenham, Kent, Chemical Manufacturer.
1908. Small, Bertram G., Leahurst, Broughton Park, Manchester, Engineer.
1898. Small, Fritz H., 28, Berwick Street, Worcester, Mass., U.S.A., Chemist.
1904. Smart, Bertram J., Government Testing Laboratory, Lithgow, N.S.W., Australia, Chemist.
O.M. Smetham, A., 16, Brunswick Street, Liverpool, Analytical Chemist.
1905. Smith, Prof. Albert W., Case Library, Cleveland, Ohio, U.S.A., Professor of Chemistry.
1898. Smith, Alf. B., Ryecroft, Glossop, Derbyshire, Bleacher and Dyers' Manager.
1897. Smith, Allan, c/o The Edward Partington Pulp and Paper Co., Reversible Falls Mill, St. John, N.B., Canada, Chemist.
1911. Smith, Andrew, c/o Leech, Neal, and Co., Ltd., Spondon, Derby, Colour Manufacturer.
1896. Smith, Andrew T., c/o Castner Kellner Alkali Co., Ltd., 257, Royal Liver Building, Liverpool, General Manager.
1905. Smith, Arthur, Town End Chemical Works, Bramley, Leeds, Chemical Manufacturer.
1912. Smith, Arthur R., c/o Messrs. J. Watson and Son, Ltd., Whitehall Soap Works, Leeds, Chemist.
1893. Smith, Edgar B., c/o Dominion Tar and Chemical Co., Box D, Transcona, Manitoba, Canada, Manager.
1906. Smith, E. A. Cappelen, c/o American Smelting and Refining Co., 165, Broadway, New York City, U.S.A., Metallurgical Engineer.
1913. Smith, Edward C., 18, Constance Street, and c/o Canadian National Carbon Co., Ltd., 99, Paton Road, Toronto, Canada, Superintendent.
1895. Smith, Dr. E. Ellsworth, Suite 80, Chemists' Building, 50, East 41st Street, New York City, U.S.A., Consulting Physiological Chemist.
1892. Smith, Ernest A., The Assay Office, Leopold Street, Sheffield, Assayer.
1911. Smith, E. Woodhouse, Central Laboratory, City Gasworks, Nechells, Birmingham, Chief Chemist.
1903. Smith, Ewing, c/o Dunlop Tire and Rubber Goods Co., Toronto, Canada, Analytical Chemist.
1903. Smith, F. M., 100, William Street, New York City, U.S.A., President (Pacific Coast Borax Co.).
1891. Smith, Francis P., 131—133, East 23rd Street, New York City, U.S.A., Chemist.
1907. Smith, Frank Morse, 100, William Street, New York City, U.S.A., Chemical Merchant.
O.M. Smith, G., Rosehall Terrace, Falkirk, Scotland, Explosives Works Manager.
1908. Smith, George A., 1433, President Street, Brooklyn, N.Y., U.S.A., Chemist (Printing Ink Manufacturing).
1907. Smith, George D., 247, Atlantic Avenue, Boston, Mass., U.S.A., Salesman.
1890. Smith, Harry E., 36, Beersford Place, East Cleveland, Ohio, U.S.A., Analytical Chemist.
1904. Smith, Henry, 83, Brownlow Road, Horwich, Bolton-le-Moors, Lancs., Analytical Chemist.
1902. Smith, Hy. Geo., Technological Museum, Harris Street, Ultimo, Sydney, N.S.W., Australia, Assistant Curator and Chemist.
1905. Smith, H. Melville, Ammunition Works, Abbey Wood, Kent, Engineer and Superintendent.
1901. Smith, H. Procter, Hightfield, Shotton Lane, Shotton, Flintshire, Metallurgical Chemist.
O.M. Smith, H. R., 1, Aubert Park, Highbury, London, N., Analytical Chemist.
1905. Smith, Hugh Dunford, 7 and 9, The Side, Newcastle-on-Tyne, Analytical Chemist.
1906. Smith, Irwin J., P.O. Box 506, Troy, N.Y., U.S.A., Salesman.
O.M. Smith, Jas., Ash Grove House, Radcliffe, Manchester.
1897. Smith, James, Sunnyside, Groes Road, Cressington, near Liverpool, Analytical Chemist.
1903. Smith, James, "Lyndhurst," Frodsham, and (Jnls.) Ditton Copper Works, Widnes, Metallurgist.
1907. Smith, Jas. C., c/o Edward Ripley and Son, Ltd., Bowling Dyeworks, Bradford, Dyer.
1893. Smith, Jas. F., 41, Grange Avenue, Scarborough, Yorks, Analytical Chemist.
1901. Smith, J. Cruickshank, King's House, King Street, London, E.C., Technical Chemist.

O.M. Smith, Dr. J. H., 21, Rue de la Pointe, Garenne-Colombes, Seine, France, Chemist.
1888. Smith, J. Tertius, Richmond House, Plaistow, Essex, Technical Chemist.
O.M. Smith, Jno. W., 7, Brookfield Street, Roslindale, Boston, Mass., U.S.A., Analytical Chemist.
1890. Smith, J. Wm., 1615, West Genesee Street, Syracuse, N.Y., U.S.A., Alkali Works Manager.
1896. Smith, Jos. Kent, 8, Hillfoot Road, Woolton, Liverpool, Metallurgical Chemist.
1910. Smith, L. Hewgill, c/o The New Transvaal Chemical Co., Delmore, Transvaal, Technical Chemist.
1911. Smith, N. Garrett, c/o Edison and Swan U.E.L. Co., Ltd., Lamp Dept. Laboratory, Ponders End, N., Analytical Chemist.
1898. Smith, R. F. Wood, 90, Lower Thames Street, London, E.C., Consulting Chemist.
1890. Smith, Dr. R. Greig, Linnean Society's House, Elizabeth Bay, Sydney, N.S.W., Bacteriologist and Chemist.
1890. Smith, Robert Watson, c/o Alex. Smith, 53, Glencairn Drive, Pollokshields, Glasgow, Chemical Works Manager.
1897. Smith, Theophilus R., 217, Hylton Road, Sunderland, Chemist.
1907. Smith, Thorn, 49, West Larned Street, Detroit, Mich., U.S.A., Chemist.
1910. Smith, Vincent, Athlone, Eagle Road, Wembley, Middlesex, Technical Chemist.
1903. Smith, Dr. Warren R., Lewis Institute, Chicago, Ill., U.S.A., Teacher.
O.M. Smith, Watson, 34, Upper Park Road, Haverstock Hill, N.W., Editor of Society's Journal.
1908. Smith, Dr. Watson, jun., Cape Explosives Works, Somerset West, C.C., South Africa, Chemist.
O.M. Smith, Wilfred, 182, West Street, Glasgow, Chemical Manufacturer.
1910. Smith, W. C., c/o The Anchor Cable Co., Leigh, Lancashire, Analytical Chemist.
1909. Smith, Wm. G., 23, Wickham Way, Parklangley, Beckenham, Kent, Chemical Merchant.
O.M. Smithells, Prof. A., F.R.S., The University, Leeds, Professor of Chemistry.
O.M. Smithers, F. O., 171, Adelaide Road, London, N.W., and (Jnls.) c/o W. E. Harrison, Technical School, Goldshill Road, Handsworth, near Birmingham, Chemical Agent.
1902. Smoot, Albert M., 99, John Street, New York City, U.S.A., Analytical Chemist.
1909. Smoot, Chas. C., III., c/o C. C. Smoot and Sons Co., North Wilkesboro', N.C., U.S.A., Tanning Chemist.
1902. Smythe, Dr. J. S., 22, Rawlinson Road, Southport, Analytical Chemist.
1888. Snape, Dr. H. Lloyd, Balholm, Lathom Road, Southport, Director of Education for Lancashire.
1908. Snell, Professor John F., Macdonald College P.O., Prov. Quebec, Canada, Professor of Chemistry.
1896. Snowdon, J., jun., Messrs. Snowdon, Sons and Co., Millwall, E., Chemical and Oil Manufacturer.
1900. Sodeau, Dr. Wm. H., Torpedofabrik, Fiume, Hungary, Chemist.
1903. Sohlman, Ragnar, Bofors, Sweden, Manager (A. B. Bofors Nobelkrut).
1894. Sohn, Chas. E., 52, Fore Street, London, E.C., and (Journals) 82, Wightman Road, Harringay, N., Analyst.
1912. Solomon, J. Bernard, 56, Priory Road, London, N.W., Tannery Chemist.
1906. Solomon, M., Birmingham Carbon Works, Witton, Birmingham, Manager.
1895. Solvay, Armand, 25, Rue Prince Albert, Brussels, Gérant de la Société Solvay et Cie.
1884. Sommer, Adolf, Corner 1st and Binney Streets, East Cambridge, Boston, Mass., U.S.A., Pharmaceutical Chemist.
1909. Sommer, Dr. Albert, Munchnerplatz 14 pt, Dresden, Germany, Engineer Chemist.
1912. Sorley, Jas., Novara, Mount Vernon, Glasgow, Analytical Chemist.
1904. Southall, A. W., Lower Priory, Birmingham, Manufacturing Chemist.
1904. Southerden, F., 11, Gordon Road, Exeter, Teacher of Chemistry.
1890. Sowerby, Thos. H., Canal Soap Works, Verney Road, Rotherhithe, S.E., Soap Manufacturer.
O.M. Sowerby, W. M., c/o United Alkali Co., Ltd., Allhusen Works, Gateshead-on-Tyne, Manager.
1887. Spackman, Chas., Rosehaugh, Clitheroe, Lancashire, Portland Cement Manufacturer.
1910. Spackman, Henry S., 2211, Chestnut Street, Philadelphia, Pa., U.S.A., President of Engineering Co.
1904. Sparre, Fin, c/o E. I. du Pont de Nemours Powder Co., Experimental Station, Henry Clay P.O., Del., U.S.A., Director.
1913. Speedy, Alan, 1, Creighton Avenue, East Ham, Essex, Technical Chemist.
1904. Speiden, C. C., 46, Cliff Street, New York City, U.S.A., Chemical Merchant.
1905. Speight, W. E., Hacken Sewage Works, Great Lever, Bolton, Chemist.
1909. Speirs, Wm., c/o W. N. Gemmill and Co., 142, Queen Street, Glasgow, Chemical Broker.
1883. Spence, D., Manchester Alum Works, Manchester, Alum Manufacturer.
1911. Spence, Dr. David, Research Laboratory, The B.F. Goodrich Co., and (Journals) P.O. Box 188, Akron, Ohio, U.S.A., Director.
1900. Spence, Howard (Journals), Audley, Broad Road, Sale, Cheshire; and Alum Works, Manchester, Chemical Manufacturer.
1909. Spence, Jno., 74, Buchanan Street, Glasgow, Analyst.
1883. Spence, Jno. W., Tiviot Colour Works, Manchester Road, Stockport, Drysalter.
1903. Spencer, A. Gordon, 601—603, Canadian Express Building, Montreal, Canada, Chemist.
1913. Spencer, Richard D., Les Savonneries Lever, Haubourdin-lez-Lille, Nord, France, Works Chemist.
1897. Sperry, Erwin S., "The Brass World," 260, John Street, Bridgeport, Conn., U.S.A., Metallurgist and Editor.
1884. Spiegel, Dr. Adolf, Messel bei Darmstadt, Germany, Analytical Chemist.
1903. Spielmann, Dr. P.E., 21, Cadogan Gardens, London, S.W., Chemist.
1906. Spiera, Dr. V. G., c/o Inchiostrificio-Veneto, Treviso, Italy, Chemist.
1889. Spies, Adolph, 21, Broadwater Down, Tunbridge Wells, Chemical Merchant.
1885. Spiller, A., 20, Holly Avenue, Newcastle-on-Tyne, Electrician.
O.M. Spiller, J., 2, St. Mary's Road, Canonbury, London, N., Consulting Chemist.
1914. Spilman, G. H., c/o The Chiswick Polish Co., Chiswick, W., Works Chemist.
1896. Spoor, J. L., Rede Court, Rochester, Kent, Portland Cement Manufacturer.
1909. Sprague, F. O., c/o Cattarangus Tanning Co., Olean, N.Y., U.S.A., Chemist.
1912. Sprent, Dr. Colin, c/o Compania Mexicana del Petroleo, El Aguila, Apartado 116, Minatitlan, Vera Cruz, Mexico, Chemical Engineer.
O.M. Squire, P. W., 413, Oxford Street, London, W., Pharmaceutical Chemist.
1910. Stadler, Hans, c/o Herr Kommerzienrat J. Stadler, Prague, Austria, Technical Chemist.
O.M Stahl, Dr. K. F., 57th Street and A. V. Ry., Pittsburgh, Pa., U.S.A., Consulting Chemist.
1914. Staley, Homer F., Standard Sanitary Manufacturing Co., Pittsburgh, Pa., U.S.A., Technical Director.
1904. Standfast, Jno. T., Prince Regent's Wharf, Silvertown, E., Chemist.
1906. Stanley, Wm., Great Barrington, Mass., U.S.A., Engineer.
1888. Stantial, Frank G., c/o Cochrane Chemical Co., Everett, Mass., U.S.A., Technical Chemist.
1885. Staples, H. J., The Old Hall, Spondon, Derby, Colour Manufacturer.

O.M. Stark, J. F., Rosedale, Bromborough, Cheshire, Works Manager.

1896. Statham, Noel, c/o West Virginia Pulp and Paper Co., 200, Fifth Avenue, New York City, U.S.A., Engineer.

1907. Stand, Joseph E., c/o W. W. Lawrence and Co., Pittsburg, Pa., U.S.A., Chemist.

1904. Stauffacher, W., 64, Oberwilerstrasse, Basle, Switzerland, Chemical Works Manager.

1895. Stead, J. Christopher, 55, Chancery Lane, London, W.C., Technical Chemist.

O.M. Stead, J. E., F.R.S., 11, Queen's Terrace, Middlesbrough-on-Tees, Analytical Chemist.

O.M. Stebbins, Dr. J. H., 50, East 41st Street, New York City, U.S.A., Analytical Chemist.

1896. Steel, Fred. W., c/o General Chemical Co., Ltd., Auburn, Sydney, Australia, Works Manager.

1900. Steel, Jno. S., Achernar, Blackburn, Melbourne, Vic., Australia, Chemist.

O.M. Steel, Thos., Colonial Sugar Refining Co., O'Connell Street, Sydney, N.S.W., Australia, Sugar Chemist.

1905. Steiger, George, c/o U.S. Geological Survey, Washington, D.C., U.S.A., Chemist.

1912. Steiner, Bernard C., Enoch Pratt Free Library, Baltimore, Md., U.S.A., Librarian.

1897. Steinhart, Dr. Oscar J., c/o Twite and Steinhart, 65, London Wall, London, E.C., Consulting Metallurgist.

1912. Steinhoff, Fred., 24, Walbrook, London, E.C., Chemical Manufacturer.

1903. Stell, S. F., 25, Henry Street, Keighley, Yorks, Teacher of Chemistry.

1887. Stenhouse, T., 166, Drake Street, Rochdale, Analytical Chemist.

1908. Stenhouse, Thos., jun., Chemical Laboratory, H.M. Dockyard, Portsmouth, Analytical Chemist.

1904. Stephen, A. E., 67, Castlereagh Street, Sydney, N.S.W., Australia, Analytical Chemist.

1911. Stephens, C. E., c/o Spies Bros. and Co., 102, Fenchurch Street, London, E.C., Chemical Merchant.

1884. Stephens, H. Chas., Avenue House, Finchley, N., Ink Manufacturer.

1892. Stephens, M. E., 57—60, Aldersgate Street, London, E.C., Ink Manufacturer.

1913. Stephenson, Guy, Bankfoot Laboratory, Crook, Co. Durham, Analyst.

1909. Stephenson, Henry H., Authors' Club, 2, Whitehall Court, London, S.W., Technical Chemist.

1909. Stephenson, Herbert F., 8, The Park, Mitcham, Surrey, Analytical Chemist.

1889. Stern, Arthur L., 148, High Street, Burton-on-Trent, Brewing Chemist.

1912. Sterne, Edward T., School of Mining, Queen's University, Kingston, Ont., Canada, Chemist.

O.M. Steuart, D. R., Osborne Cottage, Broxburn, West Lothian, Oilworks Chemist.

1903. Steven, A. B., Royal Technical College, Glasgow, Lecturer on Dyeing.

1907. Steven, Michael M., Laboratory, Glenochil Distillery, Menstrie, Scotland, Analytical Chemist.

1899. Stevenot, G. A., 280, Baltic Street, Brooklyn, N.Y., U.S.A., Chemist.

1902. Stevens, Dr. Hy. P., Laboratory, 15, Borough, London Bridge, S.E., Consulting Chemist.

1894. Stevens, Jno. H., 295, Ferry Street, Newark, N.J., U.S.A., Manufacturing Chemist.

1908. Stevens, J. Venn, 147a, Clapton Common, London, N.E., Analytical Chemist.

1902. Stevens, M. White, H.M. Patent Office, Chancery Lane, London, W.C., Chemist.

O.M. Stevenson, W., Standard Works, 95A, Southwark Street, London, S.E., Chemical Manufacturer.

1913. Steward, H. Bernard, Rose Hill House, Coseley, near Bilston, Staffs, Enamel Chemist.

1912. Stewart, Allan E., 136, Bedford Road, Toronto, Canada, Chemist.

1901. Stewart, David B. D., Aberdeen Comb Works, Hutcheon Street, Aberdeen, Managing Director.

1903. Stewart, Jas., "The Gas World," 8, Bouverie Street, Fleet Street, London, E.C., Editor.

1909. Stewart, Jeffrey, India Refining Co., McKean and Swanston Streets, Philadelphia, Pa., U.S.A., Works Manager.

1890. Stewart, Robt., 46, Westbourne Road, Luton, Chemical Works Manager.

O.M. Stewart, S., c/o Michael Nairn and Co., Ltd., Kirkcaldy, Fife, Technical Chemist.

1906. Stickland, Oliver W., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Works Chemist.

1904. Stieglitz, Dr. Julius, University of Chicago, Chicago, Ill., U.S.A., Associate Professor of Chemistry.

1904. Stiff, John T., 68, Dover Road, Northfleet, Kent, Works Chemist.

1903. Stillwell, Albert G., 76½, Pine Street, New York City, U.S.A., Chemist.

1903. Stingelin, Dr. Fritz, 31, Hongggerstrasse, Zürich, 6, Switzerland, Chemist.

1900. Stockdale, Edgar, c/o R. Dewhurst and Co., Ltd., Printworks, Batley, Yorks, Colour Mixer.

1888. Stockdale, Wm., Rosebank Printworks, Ramsbottom, near Manchester, Calico Printer.

1887. Stocks, H. B., 33, Prenton Park Road, Birkenhead, Cheshire, Analytical Chemist.

1903. Stoddard, Jesse D., 674, Woodward Avenue, Detroit, Mich., U.S.A.

1885. Stoddart, F. Wallis, Grafton Lodge, Sneyd Park, Bristol, Analytical Chemist.

1899. Stokes, Alf. W., Laboratory, Town Hall, Paddington Green, W., Public Analyst.

1910. Stokes, Edward S., c/o Metropolitan Board of Water Supply and Sewerage, Pitt Street, Sydney, N.S.W., Australia, Medical Officer.

1900. Stone, Geo. C., c/o New Jersey Zinc Co., 55, Wall Street, New York City, U.S.A., Engineer.

1899. Stone, I. F., 100, William Street, New York City, U.S.A., Chemical Merchant.

O.M. Storey, I. H., Haverbreaks, Lancaster, Chemical Manufacturer.

1914. Storie, George B., 62, Vineyard Hill Road, Wimbledon, S.W., Works Manager.

1902. Storr, Bertram V., 26, The Square, Garden Suburb, Ilford, Essex, Chemist.

1914. Stott, Augustus P., 20-26, Brunswick Place, City Road, London, N., Manager.

1909. Strachan, Jas. T., c/o Hendon Paper Works Co., Ltd., Sunderland, Works Chemist.

1912. Strange, E. Halford, 7, Staple Inn, Holborn, London, W.C., Technical Research Chemist.

1903. Strayer, D. W., 428, West King Street, York, Pa., U.S.A., Chemist.

1912. Strevens, J. E., c/o Taranaki Oil Wells, Ltd., New Plymouth, New Zealand, Technical Chemist.

1903. Strickler, Emerson H., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemist.

1909. Strivens, Percy R., Ash Villa, St. Andrew's Road South, St. Annes-on-Sea, Lancs, Analytical Chemist.

1896. Stuart, Harry T. R., Fir Bank, Woolfold, near Bury, Printworks Manager.

O.M. Stuart, T. W., 7, Livingston Drive, Sefton Park, Liverpool, Alkali Works Manager.

1896. Stubbs, Augustus J., 16, Avenida del Tibidabo, Barcelona, Spain.

1903. Sturrock, Capt. G. C., R.A., Indian Cordite Factory, Aruvankad, Nilgiris, India, Assistant Superintendent.

1908. Suart, Arthur B., c/o Johnson and Sons' Smelting Works, Paul Street, Finsbury, London, E.C., Bullion Refiner.

1895. Sudborough, Dr. J. J., Indian Institute of Science, Bangalore, India, Lecturer in Chemistry.

1889. Sulman, H. L., 44, London Wall, London, E.C., Chemist and Metallurgist.

1910. Sulzer, Albert F., 16, Beverly Street, Rochester, N.Y., U.S.A., Chemical Engineer.

1895. Summers, Bertrand S., c/o The Summers Fiber Co., Port Huron, Mich., U.S.A., Electro-Chemist.

1907. Sundar-Ram, Minakshi, c/o Parry and Co., Ranipettai, N. Arcot, Madras, India, Agricultural Chemist.
1913. Sundeman, G., c/o C. E. Davis' Packing Co., Fleeton, Va., U.S.A., Chemist.
1912. Sutcliffe, J. A. L., c/o Price's Co., Ltd., Belvedere, Kent, Analytical Chemist.
1906. Sutermeister, Edwin, c/o S. D. Warren and Co., Cumberland Mills, Westbrook, Maine, U.S.A. Chemist.
1884. Sutherland, D. A., 26, Victoria Street, Westminster, S.W., Consulting Technical Chemist.
1909. Sutherland, Daniel M., Ashgrove, Sunbury Common, Middlesex, Works Manager.
1894. Sutherland, Geo., Croft Cottage, Bonhill, Scotland, Chemist.
1887. Sutherland, Jas., c/o British Aluminium Co., Ltd., Larne Harbour, Co. Antrim, Ireland, Chemist.
1906. Sutherland, John, c/o The Bauxite Refining Co., Ltd., Hebburn-on-Tyne, Manager.
O.M. Sutherland, R. M., Lime Wharf Chemical Works, Falkirk; and Solsgirth, Dollar, Chemical Manufacturer.
O.M. Sutton, Dr. Francis, Norfolk County Laboratory, Redwell Street, Norwich, Analytical Chemist.
1886. Sutton, F. Napier, 6, Grosvenor Gardens, Cricklewood, N.W., Alkali Works Inspector.
1900. Sutton, W. Lincolne, Redwell Street, Norwich, Public Analyst.
O.M. Swan, Sir Jos. W., F.R.S., Overhill, Warlingham, Surrey, Chemist and Electrician.
1913. Swan, J. Waldron, 211, Castle Street, Luton, Beds, Gas Works Chemist.
1906. Sweet, Everell F., 52, Union Street, Boston, Mass., U.S.A., Importer.
1905. Swenarton, W. Hastings, 2, Rector Street, New York City, U.S.A., Patent Lawyer.
1904. Swindells, Seth, Liverpool Road, Kidsgrove, Stoke-on-Trent, Chemist.
1912. Swinden, Dr. Thos., 12, Nether Edge Road, Sheffield, Metallurgist.
1901. Swinton, Ralph S., c/o W. J. Bush and Co., Inc., Linden, N.J., U.S.A., Analytical Chemist.
1912. Sykes, Charles D., 95, Vicarage Road, Langley, near Birmingham, Chemical Works Manager.
1902. Sylow, Paul L. P. G., New Farm Sugar Refinery, Brisbane, Queensland, Analytical Chemist.
1906. Symes, Langford P., Belfast Freezing Works, Christchurch, New Zealand, Chemist.
1906. Symonds, Abram E., Wick Lane Colour Works, Old Ford Road, Bow, E., Colour Manufacturer.
1910. Szilagyi, L. F., 39, Belsize Avenue, London, N.W., Consulting Engineer.

T

1895. Taber, G. H., 814, Frick Building, Pittsburg, Pa., U.S.A., General Manager (Gulf Refining Co.).
1910. Tainsh, Peter, Belmont, Sorbie Road, Ardrossan, Ayrshire, Technical Chemist.
1909. Tait, Walter Scott, Church Farm, Bebington, Cheshire, Works Manager.
1896. Takagi, T., 10, Nishikatamachi, Hongo, Tokyo, Japan, Chemical Engineer.
O.M. Takamatsu, T., 13, Nishikatamachi, Hongo, Tokyo, Japan, Analytical Chemist.
O.M. Takamine, Dr. Jokichi, 550, West 173rd Street, New York City, U.S.A., Engineer.
1890. Takayama, Jintaro, Nando Machi 26, Ushigome, Tokyo, Japan, Director (Imperial Industrial Experiment Station).
1912. Talley, Herbert, c/o Independent Powder Co. of Mo., Joplin, Mo., U.S.A., General Manager.
1910. Tanahashi, Dr. T., 486, Sendamachi, Fukagawa, Tokyo, Japan, Manufacturing Chemist.
1898. Tanaka, Keishin, Matsuba Hotel, Kudansaka, Uye, Tokyo, Japan, Chemist.
1900. Tankard, Arnold R., 67, Ferens Avenue, Cottingham Road, Hull, Analytical Chemist.
1911. Tarver, Percy, 2095, East 36th Street, Cleveland, Ohio, U.S.A., Chemist (Sherwin-Williams Co.).
O.M. Tate, F. H., 9, Hackins Hey, Liverpool, Analytical and Technical Chemist.
1910. Tatlock, Chas. S. A., c/o The Standard Chemical Products Co., Ltd., Irvine, Scotland, Analytical Chemist.
O.M. Tatlock, R. R., 156, Bath Street, Glasgow, Consulting Chemist.
1902. Tatters, Hugh Lee, 10, Birchfield Road, Widnes, Analytical Chemist.
1906. Tattersfield, Frederick, 96, Bewick Road, Gateshead-on-Tyne, Analyst.
1905. Taveau, René de Mortemer, 1809, North Calvert Street, Baltimore, Md., U.S.A., Chemist.
1901. Tayler, Jno. Bernard, Anglo-Chinese College, Tientsin, North China, Chemist.
1903. Taylor, Alvin M., c/o General Chemical Co., Hegewisch, Ill., U.S.A., Chemist.
1902. Taylor, Arthur P., c/o John Taylor and Co., 531, Front Street East, Toronto, Ont., Canada, Soap Manufacturer.
1907. Taylor, C. Marshall, Port Reading, N.J., U.S.A., Chemist.
1902. Taylor, Edward R., Penn Yan, N.Y., U.S.A., Manufacturing Chemist.
1886. Taylor, G. Crosland, Crane House, Crane Wharf, Chester, Electrical Engineer.
1894. Taylor, G. Midgley, Caxton House, Westminster, S.W., Analytical Chemist.
O.M. Taylor, H. E., 1, Alexandra Park Gardens, Glasgow, Lead Works Manager.
1883. Taylor, Jas., "Greenleaf," Brierley Street, Mosman, N.S.W., Australia, Government Metallurgist.
1898. Taylor, Jas. M., Tynevale, Groes Road, Cressington, Liverpool, Analytical Chemist.
1888. Taylor, J. Scott, North London Colour Works, Spring Place, Kentish Town, N.W., Technical Chemist.
1896. Taylor, Martin, "The Clough," Buckhurst Hill, Essex, Chemical Works Manager.
1901. Taylor, Sidney H., 63, Wolstenholme Road, Sharrow, Sheffield, Works Chemist.
1898. Taylor, Walter, 475, Grosvenor Place, Limefield, Bury, Lancs, Technical Chemist.
1905. Taylor, Wm. H., 36, Glenhouse Road, Eltham Park, Kent, Chemist.
1887. Teanby, G. W. A., Elvin Lodge, East Dereham, Norfolk, Analytical Chemist.
1899. Teas, Wm. Holmes, Marion, Va., U.S.A., Chemist.
1913. Tebbutt, Oswold N., 4, Salisbury Villas, Cambridge, Cement Works Manager
O.M. Teed, Dr. F. L., Chem. Laby., 9, Mincing Lane, London, E.C., Analytical Chemist.
1905. Teeple, Dr. J. E., 50, East 41st Street, New York City, U.S.A., Director.
1908. Teichfeld, Arnold, Tasna 6, Warsaw, Russia, Chemist in Ceramic Industry.
1904. Teller, George L., 31, North State Street, Chicago, Ill., U.S.A., Chemist.
1906. Tempany, Harold A., Government Laboratory, St. John's, Antigua, West Indies, Analyst.
1913. Tennant, C. A., c/o C. Tennant Sons and Co. (Montreal), Ltd., C.P.R. Tel. Chambers, Montreal, Canada, Chemical Importer and Agent.
1884. Tennant, Jas., Fairlie, Ayrshire, Lead and Colour Manufacturer.
1913. Tennant, Robt., 4, Park Terrace, Queen's Drive, Crosshill, Glasgow, Analytical Chemist.
1896. Tennille, Geo. F., c/o Southern Cotton Oil Co., 206, Bay Street East, Savannah, Ga., U.S.A., Chemist.
1908. Terleski, Fred. H., 11, Oaklands Road, Kersal, Manchester, Technical Chemist.
1911. Terrey, Augustus G., c/o The Limmer Asphalte Paving Co., Ltd., Leamouth Wharf, Orchard Place, Blackwall, E., Chemist.
1884. Terry, Hubert L., (Journals) Fairfield House, Brook Road, Fallowfield, Manchester; and (Laboratory) 23, Hopwood Avenue, Manchester, Technical Chemist.

O.M. Tervet, R., 68, Windsor Road, Leyton, Essex, Oil Works Manager.
1893. Tetley, C. F., Messrs. Jos. Tetley and Son, The Brewery, Leeds, Brewer.
1908. Thatcher, Dr. C. J., 1352, Hudson Terminal Building, New York City, U.S.A., Consulting Chemist and Patent Expert.
1903. Thatcher, Ed. J., The Manor House, Chew Magna, near Bristol, Merchant and Manufacturer.
1909. Thaxter, Gerald N., c/o Brewer and Co., Worcester, Mass., U.S.A., Chemist.
1908. Theis, Dr. Friedrich C., Konigsteinerstrasse 60, Höchst a/Main, Germany, Chemist.
1910. Thom, T. Mathieson, Woodlands, Cheshunt, Herts, Chemical Engineer.
1908. Thom, Wm. H., 1024, Dovercourt Road, Toronto, Canada, Chemist.
1911. Thomas, Benjamin F., 808, Pine Street, Chattanooga, Tenn., U.S.A., President, Cocalola Bottling Co.
1911. Thomas, D. Hibbert, 56, Waun Road, Morriston, Glamorganshire, Chemical Works Manager.
1912. Thomas, Frederick, c/o Williams Bros. and Co., Colour Manufacturers, Hounslow, Middlesex, Chemist and Works Manager.
1894. Thomas, H. Russell, Broad Plain Soap Works, Bristol, Soap Manufacturer.
1909. Thomas, John, Highfield, Brettell Lane, near Stourbridge, Analytical Chemist.
O.M. Thomas, J. W., Overdale, Shortlands, Kent, Analytical Chemist.
1902. Thomas, Nehemiah M., Roseville Avenue, Pymble, N.S.W., Australia, Inspector.
1901. Thomas, Octavius, Gas and Water Offices, Pentre, Glamorganshire, Gas and Water Engineer.
1908. Thomas, Oswald J. D., c/o Canada Cement Co., Ltd., Plant No. 3, Hull, Quebec, Canada, Analytical Chemist.
1888. Thomas, S. Percy, c/o Baird and Tatlock, 14, Cross Street, Hatton Garden, London, E.C., Technical Chemist.
1898. Thomas, Wm. Harrison, jun., c/o The Apponang Co., Apponang, R.I., U.S.A., Printworks Chemist.
1905. Thomlinson, Wm., Seaton Carew Ironworks, West Hartlepool, Ironmaster.
1905. Thompson, Alf. J., c/o R. W. Greeff and Co., Thames House, Queen Street Place, London, E.C., Chemical Merchant.
1885. Thompson, Prof. Claude M., 38, Park Place, Cardiff, Professor of Chemistry.
1898. Thompson, Edw. C., Froyle House, 42, Westcombe Park Road, Blackheath, S.E., Manufacturing Chemist.
1909. Thompson, Edwin, 25, Sefton Drive, Liverpool, Manufacturing Chemist.
1893. Thompson, G. Rudd, 69, Dock Street, Newport, Mon., Analytical and Consulting Chemist.
1895. Thompson, Gustave W., 129, York Street, Brooklyn, N.Y., U.S.A., Chemist.
1913. Thompson, Howard, 20, Kingsway, Northwich, Cheshire, Analytical Chemist.
1907. Thompson, Jas. G., Donegall Quay Mills, Belfast, Ireland, Corn Miller.
1903. Thompson, Jno. T., Corporation Sewage Works, Knostrop, Leeds, Analyst.
1912. Thompson, Kenworthy J., 644, Mabbett Avenue, Milwaukee, Wis., U.S.A., Chemist, Federal Rubber Works.
1907. Thompson, Milton S., 72, Broad Street, Boston, Mass., U.S.A., Manufacturer.
O.M. Thompson, W. P., Patent Office, 6, Lord Street, Liverpool, Patent Agent.
1896. Thomsen, Alonzo L., Maryland Club, 1, East Eager Street, Baltimore, Md., U.S.A., Manufacturing Chemist.
1884. Thomson, G. Carruthers, 53, Bedford Road, Rock Ferry, Birkenhead, Engineer.
1907. Thomson, H. N., 211, South Sixth Street, Salt Lake City, Utah, U.S.A., Metallurgist.
1891. Thomson, Jas. M., Royal Gunpowder Factory, Waltham Abbey, Essex, Manager (Cordite Branch).
1884. Thomson, Robt. T., 156, Bath Street, Glasgow, Analytical Chemist.
1899. Thomson, Thos., c/o Waterproofing Co., Barrhead, near Glasgow, Manufacturer.
O.M. Thomson, W., Royal Institution Laboratory, 79A, Princess Street, Manchester, Analytical and Consulting Chemist.
1890. Thomson, Wm. Thos., Royal Gunpowder Factory, and (Journals) Forest View, Honey Lane, Waltham Abbey, Essex, Explosives Chemist.
1902. Thorburn, Jas., 30, Cromartie Avenue, Newlands, Glasgow, Analytical Chemist.
1910. Thorne, Carl B., c/o Riordan Paper Co., Hawkesbury, Ontario, Canada, Manager.
O.M. Thorne, Dr. L. T., Highlands, The Crescent, Belmont, Surrey, and (Journals) Southampton Wharf, Battersea, S.W., Technical Chemist.
1907. Thornewell, A. R., 139, Vicarage Road, Langley, near Birmingham, Works Chemist.
O.M. Thorneycroft, Wallace, (Jnls.) Plean House, Plean, Stirling, and 113, St. Vincent Street, Glasgow, Technical Chemist.
1904. Thornley, Thomas, 19, Hope Street, Glasgow, Chemical Manufacturer.
1887. Thornton, H., Redbourn, Ashford, Middlesex, Analytical Chemist.
1899. Thornton, Wm., c/o J. S. MacArthur and Co., Porcupine, North Ontario, Canada, Chemist.
1895. Thorp, Dr. Frank H., Mass. Inst. of Technology, Boston, Mass., U.S.A., Assistant Professor of Industrial Chemistry.
1911. Thorp, John W., Granville Street, Barnsley, Yorks, Tar Works Manager.
1907. Thorp, Thos., Moss Bank, Whitefield, near Manchester, Engineer.
1906. Thorp, Walter, Sorrentoville, Dalkey, Co. Dublin, Ireland, Analytical Chemist.
O.M. Thorpe, Sir Edward, C.B., F.R.S., Whinfield, Salcombe, South Devon, Professor of Chemistry.
1905. Thorpe, Prof. J. F., F.R.S., The Imperial College, South Kensington, London, S.W., Professor of Organic Chemistry.
1905. Thresh, Dr. John C., Chelmsford, Essex, Medical Officer of Health and Sanitary Expert.
1898. Thurnauer, Dr. Gustav, c/o Aurora Metal Co. Aurora, Ill., U.S.A., Chemist.
1904 Thurston, Azor, Grand Rapids, Ohio, U.S.A., Chemist
1904. Tickle, Thos., Laboratory, 83, Queen Street, Exeter, Analyst.
1913. Tilburn, Charles, The Australian Explosives and Chemical Co., Ltd., Deer Park, Vic., Australia, Works Manager and Explosives Chemist.
1908. Tillberg, Erik W., Westervik, Sweden, Extract Manufacturer.
1900. Tilley, Jas. W., 35A, Southwark Street, London, S.E., Research Chemist.
1906. Tillson, Henry E., 5946, Christian Street, Philadelphia, Pa., U.S.A., Dyer.
1901. Timmans, W. G., The Basford Chemical Co., Ltd., Basford, Nottingham, Chemical Manufacturer.
1912. Timmis, Shirley S., Messrs. Wm. Gossage and Sons, Ltd., Soap Works, Widnes, Lancs, Soap Manufacturer.
1905. Tindall, W. B., 39, St. Mary Street, Toronto, Canada, Secretary and Treasurer.
1894. Tipler, Fred. C., 48, Brooklyn Street, Crewe, Analytical Chemist.
1907. Tischbein, Dr. Robert, The Heyden Chemical Works, Garfield, N.J., U.S.A., Chemist.
1890. Tobey, C. H., Burks Falls, Ontario, Canada, Tannery Chemist.
1894. Toch, Maximilian, 320, Fifth Avenue, New York City, U.S.A., Chemist.
1886. Todd, A. M., c/o The A. M. Todd Co., Kalamazoo, Mich., U.S.A., Manufacturing Chemist and Distiller of Essential Oils.

1913. Tomlinson, George G., Anglo-Chilian Nitrate and Railway Co., Tocopilla, Chile, South America, Chemist.
1914. Tompkin, Albert, 77, Market Side, Bulwell, Nottingham, Pharmacist.
O.M. Toms, F. Woodland, States Analyst's Office, St. Heliers, Jersey, Analytical Chemist.
1902. Tone, Frank Jerome, c/o The Carborundum Co., Niagara Falls, N.Y., U.S.A., Manager.
1909. Tonry, Wm. S., Passaic Street, near Elm Street, Maywood, N.J., U.S.A., Chemical Engineer.
1913. Toppin, Richmond D., Millett Street, Hurstville, Sydney, N.S.W., Chemist.
1907. Torrey, Dr. Joseph, Craigie Lea, Blundellsands, Liverpool, Engineer.
O.M. Towers, J. W., Widnes, Lancashire, Analytical Chemist.
1907. Towler, A. E., c/o Sulphide Corporation, Cockle Creek, N.S.W., Australia, Chemist.
1909. Townend, Harry, Public Library, Bury, Lancashire, Librarian.
1897. Towse, Walter, Elswick Leather Works, Newcastle-on-Tyne, Technical Chemist.
1904. Toyne, Francis D., c/o Kelsall and Kemp, Ltd., Woodhouse Mills, Norden, near Rochdale, Chemist.
1894. Traphagen, Dr. Frank W., Colorado School of Mines, Golden, Colo., U.S.A., Professor of Metallurgy and Assaying.
1900. Traquair, Jno., Ayer, Mass., U.S.A., Analytical Chemist.
1906. Travell, Norman E., Grosvenor Avenue, Mapperley Park, Nottingham, Lace Dresser.
1893. Travers, Prof. Morris W., F.R.S., Indian Institute of Science, Bangalore, India, Director.
1889. Trechmann, A. O., The Old Palace, Rochester, Kent, Cement Manufacturer.
1911. Trechmann, C. T., Warren Cement Works, Hartlepool, Cement Manufacturer.
1895. Treharne, F. Gwilym, Wrangbrook, Llanishen, near Cardiff, Analytical Chemist.
1885. Trewby, Herbert, Lampetts, Fyfield, Essex, Analytical Chemist.
1909. Trier, Thorvald G., 237, West 22nd Street, New York City, U.S.A., Technical Chemist.
1901. Trigger, Oliver, Chem. Dept., Royal Arsenal, Woolwich, S.E., Analytical Chemist.
1898. Tripp, Dr. E. Howard, 26, Chaucer Road, Bedford, Science Master.
O.M. Trobridge, A., c/o Trobridge and Co., Ltd., Heworth Shore, Felling-on-Tyne, Technical Chemist.
1897. Trotman, Saml. R., The City Laboratory, 1, Regent Street, Nottingham, City Analyst.
1900. True, Percival E., 392, Raymond Street, Elgin, Ill., U.S.A., Chemical Engineer.
1887. Tsukiyama, S., 2nd of No. 2116, Fukiai-chō, Kobe, Japan, Paper Mills Chemist.
1894. Tucker, Alex. E., 55, Station Street, Birmingham, Metallurgist and Chemist.
1897. Tucker, Samuel A., Columbia University, New York City, U.S.A., Tutor in Industrial Chemistry.
1886. Tuer, Arthur H., Douglas House, Worthington, near Wigan, Analytical Chemist.
1903. Tufts, C. G., c/o Semet-Solvay Co., Syracuse, N.Y., U.S.A., Chemical Engineer.
1909. Tulloch, Capt. T. G., Bank Buildings, St. James' Street, London, S.W., Director of Public Companies.
1901. Tulloch, Wm. F., c/o Joseph Watson and Sons, Ltd., Whitehall Soap Works, Leeds, Merchant.
1914. Tungay, Sydney J., Haughton's Ltd., 30, St. Mary at Hill, London, E.C., Chemical Engineer.
1909. Tunks, Dr. F. R., Powder Mills, Tonbridge, Kent, Manager.
1904. Tunnell, Raymond W., 251, West Walnut Lane, Germantown, Philadelphia, Pa., U.S.A., Manufacturer.
1899. Turnbull, Dr. Andrew, 18, Hackins Hey, Liverpool, Consulting Chemist.
1888. Turnbull, G. W., Ash Cottage, North Road, Carnforth, Lancashire, Metallurgical Chemist.
1904. Turnbull, R. H., Messrs. Turnbull's (Glasgow) Ltd., 20, Strand Road, Calcutta, India, Chemist.
1884. Turnbull, W. S., 38, Bath Street, Glasgow, Chemical Manufacturer.
1911. Turner, Prof. A. J., Technical Institute, Byculla, Bombay, India, Professor of Chemistry.
1902. Turner, Basil, 83, Pitt Street, Sydney, N.S.W., Australia, Metallurgist.
1902. Turner, Jos., c/o Read Holliday and Sons, Ltd., and (Jnls.) Azo House, Birkby, Huddersfield, Chemist.
1905. Turner, Prof. Thomas, 75, Middleton Hall Road, King's Norton, Birmingham, Professor of Metallurgy.
1897. Turney, Fred. N., 12, Dieghem Straat, Saventham, near Brussels, Belgium, Leather Dresser.
1887. Turney, Sir J., Trent Bridge Leather Works, Nottingham, Tanner.
1908. Turnill, Thos. W., c/o Atlas Preservative Co., Windmill Lane, Deptford, S.E., Works Chemist.
1905. Tutwiler, Carrington C., Real Estate Trust Building, Philadelphia, Pa., U.S.A., Consulting Gas Chemist.
1890. Tweedy, Jas., 245, Burdett Road, Limehouse, E., Metallurgical Chemist.
1905. Twigg, Geo. F., 57, Val Plaisant, St. Heliers, Jersey, Gas Works Chemist.
1891. Twitchell, E., Wyoming, Ohio, U.S.A., Candle Works Manager.
1913. Twomey, Jerome, 21, Onslow Road, Elm Park, Liverpool, Research Chemist.
O.M. Twynam, T., Wynyard House, Coatham Road Redcar, Yorks, Metallurgist.
1904. Tyler, Chas. R., c/o Dr. Francis Wyatt, 402, West 23rd Street, New York City, U.S.A., Analytical Chemist.
O.M. Typke, P. G. W., Lawn House, New Malden, Surrey, Chemical Manufacturer.
O.M. Tyrer, Thos., Stirling Chemical Works, Stratford, E.; and (Journals) 14, Sandwell Mansions, West End Lane, N.W., Chemical Manufacturer.

U

1907. Udal, John P., Ridge Road, Berea, Durban, Natal, Engineer.
1894. Uhlig, E. C., Citizens' Gas Works, Fifth and Hoyt Streets, Brooklyn, N.Y., U.S.A., Chemist.
1900. Uhlig, W. C., c/o Hygeia Distilled Water Co., 349, West 12th Street, New York City, U.S.A., Chemist.
O.M. Umney, C., Fernbrake, Branksome Wood Road, Bournemouth; and (Journals) 48, Southwark Street, London, S.E., Manufacturing Chemist.
1905. Umney, John C., 48, Southwark Street, London, S.E., Wholesale Druggist.
1889. Underhill, Thos. J., "Stanley," Quernmore Road, Bromley, Kent, Inspector of Stores.
1885. Underwood, G. R., 10, Emerson Street, Peabody, Mass., U.S.A., Glue Works Chemist.
1904. Uyeda, Toyokitsu, 54, Matsugayechō Kitaku, Osaka, Japan, Chemist.

V

1911. Vakil, Kapibram H., No. 5, Santa Cruz, Bombay, India, Chemist.
1896. Van der Linde, Harold, c/o Century Rubber Co., Plainfield, N.J., U.S.A., President.
1895. Vanderpoel, Dr. Frank, 175, Park Avenue, Orange, N.J., U.S.A., Chemist.
1913. Van Doren, W. V., 1646, Garfield Boulevard, Chicago, Ill., U.S.A., Chemist.
1903. Van Dyck, Edwin M., 57, Greene Street, New York City, U.S.A., Chemist and Ink Maker.
1897. Van Gelder, Arthur P., c/o Hercules Powder Co., Kenvil, N.J., U.S.A., Superintendent.
1891. Van Gundy, Chas. P., Laboratory, B. and O. R. R., Baltimore, Md., U.S.A., Metallurgical Chemist.

1896. Van Laer, Norbert, Truman's Brewery, Burton-on Trent, Brewer and Chemist.
1897. Van Marken, J. C., 10, Amalia Straat, The Hague, Holland, Chemical Engineer.
1888. Vargas-Vergara, J. M., Apartado No. 120, Bogota, Colombia, S. America, Metallurgical Chemist.
1910. Vass, David, Gas Works, Perth, Manager.
1912. Ventress, Ernest W. S., c/o Messrs. Lever Bros., Kabushiki Kaisha, P.O. Box Sannomiya 174, Kobe, Japan, Oil Mill Manager.
1898. Verity, Ben., 550, Hood Street, Fall River, Mass., U.S.A., Print Works Chemist.
1904. Vernon, Dr. R. H., Chemical Engineer.
1908. Vickers, Benj. Threlfall, Gascoigne Street, Boar Lane, Leeds, Oil Merchant.
O.M. Vickers, Wm., c/o Thos. Vickers and Sons, Miles Platting, Manchester, Chemical Manufacturer.
1907. Vietinghoff-Scheel, Dr. Karl Freiherr von, "Chemiker-Zeitung," Cöthen (Anhalt), Germany, Editor in Chief.
1908. Vieweg, Dr. Walter, Ganghoferstrasse 11, Frankfurt a M., Germany, Chemist.
1909. Virolleaud, Leopold, 3, Rue de Paris, St. Denis, Seine, France, Chemical Engineer.
1897. Vlies, Leonard E., Belmont, Gowan Road, Alexandra Park, Manchester.
O.M. Voelcker, E. W., 1, Tudor Street, London, E.C., Analytical and Consulting Chemist.
1887. Voelcker, Dr. J. A., 20, Upper Phillimore Gardens, Kensington, W., Agricultural Chemist.
1897. Vogel, Julius L. F., Parliament Mansions, Victoria Street, Westminster, S.W., Engineer.
1899. Vogeler, Gustav, 17, Philpot Lane, London, E.C., Merchant.
1897. Voorhees, Louis A., 111, Carroll Place, New Brunswick, N.J., U.S.A., Agricultural Chemist.
1899. Voorhees, Samuel S., Bureau of Standards, Washington, D.C., U.S.A., Chemist.
1902. Vorisek, Dr. Anton, College of Pharmacy, 115—119, West 68th Street, New York City, U.S.A., Instructor.
1885. Voss, Hermann, Holstein, Silver Lane, Purley, Surrey, Manure Works Manager.
1899. Voss, Walter A., Carlton Chemical Works, Glengall Road, Millwall, E., Manufacturing Chemist.

W

1896. Wachtel, Gregory, Alexandrowski Prospect 15, St. Petersburg, Russia, Chemical Engineer.
1905. Waddell, Montgomery, 30, Church Street, New York City, U.S.A., Consulting Engineer.
1911. Waddock, Wm. P., 666, Harris Street, Ultimo, Sydney, N.S.W., Milk Analyst.
1913. Wade, Albert J., 33, Kimberley Avenue, East Ham, E., Sugar Analyst.
1902. Wade, Frank, 26, St. Ronan's Avenue Southsea, Analytical Chemist.
1890. Wade, Jas. L., 28, West Kensington Gardens, London, W., Chemical Manufacturer.
1889 Wadman, W. E., 102, Lord Avenue, Bayonne, N.J., U.S.A., Manufacturing Chemist.
1911. Waele, Armand de, c/o Linoleum Manufacturing Co., Staines, Technical Chemist.
1897. Wagner, Dr. Theodore B., Room 2229, 17, Battery Place, New York City, U.S.A., Chemist.
1893. Wagner, W. G., 12, North Common Road, Ealing, W., Manufacturing Chemist.
1906. Wagstaffe, Dr. E. A., 22, Blackfriars Street, Manchester, Analytical Chemist.
1906. Wahl, Dr. Robert, 1135—1147, Fullerton Avenue, Chicago, Ill., U.S.A., President, Brewers' School.
1895. Wainwright, Wm., c/o Spooner and Bailey, Manure Works, Eling, near Southampton, Chemist.
1908. Wait, Douglas, c/o R. Gay and Co., Ltd., Langthorne Works, Stratford Market, London, E., Analytical Chemist.
1901. Waite, C. Nelson, c/o The Jessop and Moore Paper Co., Delaware Mills, Wilmington, Del., U.S.A., Chemist.
1899. Wakefield, Wm. C., Mill Street East, Savile Town, Dewsbury, Chemical Manufacturer.
1905. Waldenberger, Dr. C. A., 62, Mercer Street, Jersey City, N.J., U.S.A., Chemist.
1894. Waldman, Louis J., 78, Willett Street, Albany, N.Y., U.S.A., Aniline Dye Manufacturer.
1895. Waldstein, Dr. Martin E., 23, Broadwater Down, Tunbridge Wells, Kent, Manufacturing Chemist.
1887. Walker, Archibald, Newark Castle, Ayr, Scotland, Distiller.
1913. Walker, F. H., jun., 3, Stannington Grove, Heaton, Newcastle-on-Tyne, Technical Chemist.
1914. Walker, Fred. W., Rosemont, Bath Street, Saltburn, Yorks, Analytical Chemist.
1908. Walker, George, c/o Anglo-Persian Oil Co., Mohammera, Persia, via Bombay, Analytical Chemist.
1913. Walker, Henry, c/o C. von Grueber, 31 and 33, High Holborn, London, W.C., Chemical Engineer.
1897. Walker, H. V., 193, Lincoln Avenue, Newark, N.J., U.S.A., Chemist.
1894. Walker, Prof. Jas., D.Sc., F.R.S., 5, Wester Coates Road, Edinburgh, Professor of Chemistry (University of Edinburgh).
1897. Walker, Jas. W., Marine Lodge, Irvine, Scotland, Chemical Manufacturer.
1906. Walker, Jas. W., Stonydale, Oakamoor, Stoke-on-Trent, Assayer.
1902. Walker, Jno. H., Gourepore Works, Naihati, E.B.S.R., Bengal, India, Chemist.
1910. Walker, John S., Hiratsuka, Sagami, Japan, Explosives Chemist.
1884. Walker, S. R., Fern Bank, Starling Road, Radcliffe, Manchester, Foreman Dyer.
1912. Walker, Prof. W. O., Dept. of Chemistry, School of Mining, Kingston, Ont., Canada, Professor of Chemistry.
1895. Walker, W. Sloane, c/o Walker, Ltd., Litherland, near Liverpool, Tanner.
1897. Wallace, Edwin C., 92, Corey Street, West Roxbury, Mass., U.S.A., Chemist.
1883. Wallace, Robert, 20, Murrayfield Avenue, Edinburgh, Distiller.
1897. Wallace, Robt. A., 66, Holland Road, London, W., Chemical Manufacturer.
O.M. Waller, Dr. Elwyn, 7, Franklin Place, Morristown, N.J., U.S.A., Professor of Chemistry.
1906. Wallerstein, Leo, 177, West 72nd Street, New York City, U.S.A., Chemist.
1899. Wallerstein, Dr. Max, 24—26, West 30th Street, New York City, U.S.A., Chemist.
1913. Walmsley, Samuel R., c/o Chillagoe, Ltd., Forsayth, North Queensland, Australia, Assayer.
1886. Walsh, F. T., 12, Valentine Street, West Newton, Mass., U.S.A., Colour Printer.
1901. Walsh, Lionel O. P., c/o Dominion Tar and Chemical Co., Ltd., Sydney, Cape Breton, Canada, Chemist.
1903. Walsh, Peter H., P.O. Box 569, Magog, Quebec, Canada, Analytical Chemist.
1904. Walther, Wm., Holzapfel's Compositions Co., Ltd., Heworth Shore, Felling-on-Tyne, Chemist and Works Manager.
1908. Walton, Robert H., Railway Stores, Eveleigh, Sydney, N.S.W., Analyst.
1902. Walton, Thos. U., Colonial Sugar Refining Co., Ltd., O'Connell Street, Sydney, N.S.W., Australia, Analytical Chemist.
1911. Walton, Wm. Keighley, Beechwood, Upper Rushton Road, Thornbury, Bradford, Analyst.
1895. Want, W. Philip, 194—200, Bishopsgate, London, E.C., Pharmacist and Editor.
1901. Warburton, Frank, 50, Rosebery Road, Muswell Hill, N., Manager.
1904. Warburton, George H., 75, Mill Lane, West Hampstead, N.W., Analytical Chemist.
1896. Warburton, Thos., 14, Sunny Bank Road, Longsight, Manchester, Chemist.
1912. Ward, Dudley R., 83, St. Paul's Street West, St. Catherine's, Ontario, Canada, Analytical Chemist.

O.M. Ward, Geo., Messrs. Hirst, Brooke, and Hirst, Ltd., Millgarth Mills, Leeds, Chemical Manufacturer.

1891. Ward, G. J., Hallam Fields, Ilkeston, Notts, Civil Engineer.

1898. Ward. John. Barnstone Blue Lias Lime Co., Ltd., Barnstone, Notts, Manager.

1899. Ward, Wm. J., 11, Manor Road, Sale, Manchester, Chemist.

1908. Wardleworth, Theo. H., 168, Côte Saint Antoine Road, Westmount, Montreal, Canada, Manufacturing Chemist.

1902. Waring, W. Geo., Webb City, Mo., U.S.A., Metallurgical Chemist.

1913. Warner. Arthur L. D., P.O. Box 203, Edgewater, N.J., U.S.A , Sugar Refiner.

1899. Warnes, Arthur R., 13—17, Green Lane, Hull, Consulting Technical Chemist.

1912. Warren. E. Bruce, c/o Indian Rubber and Gutta Percha Telegraph Works Co., Silvertown, E., Consulting Analytical Chemist.

1890. Warren, Fiske, c/o S. D. Warren and Co., Laboratory Cumberland Mills, Maine, U.S.A., Paper Manufacturer.

1901. Warren, Jno. E., Eagle Chemical Works, Barchester Street, Poplar, E., Tar Distiller.

1907. Warren, W. H., Gas Works, Beckton, E., Gas Engineer.

1912. Warriner, C. E., City Analyst's Office, Fort William, Ont., Canada, Analyst and Bacteriologist.

1911. Washburn, Frank S., Stahlman Building, Nashville, Tenn., U.S.A., President, American Cyanamid Co.

1913. Wassmer, Dr. Eugene, Chapel Place Laboratory, Maundy Place, Broadway, Westminster, S.W., and (Journals) 4, Rue de l'Ecole de Chimie, Geneva, Chemist.

1885. Waterfall. W. B., c/o Avon Manure Co., Bristol; and (Journals) Thirlmere, Clavering Road, Redland, Bristol, Manure Manufacturer.

1902. Watkins, E. J., 72, King's Road, Peckham. S.E., Works Chemist.

1898. Watkins, Willard H., c/o Schoellkopf, Hartford, and Hanna Co., P.O. Drawer 57, Buffalo, N.Y., U.S.A., Chemist.

1894. Watmough, Benj., 1, Ryeburn, Stanley Road; and (Journals) c/o Brotherton and Co., Ltd., Ammonia Works, Wakefield, Chemist.

1884. Watson, Chas., Rose Bank, School Road, Moseley, Birmingham, Manufacturing Chemist.

1894. Watson, Chas. Ernest, 33, Oxford Road, St. Anne's on Sea, Lancashire, Chemical Assistant

1908. Watson, C. I. Wilkinson, c/o Wailuku Sugar Co., Wailuku, Maui, Hawaiian Islands, Chemist.

1901. Watson, Herbert J., 64, Peel House Lane, Widnes, Chemist.

1903. Watson, H. W., Rose Villa, Roper Avenue, Gledhow, Leeds, Analytical Chemist.

1894. Watson, Jas., Tyne View, Hebburn-on-Tyne, Alkali Works Manager.

1891. Watson, Jno., Langdon, Beaconsfield Road, Blackheath, S.E., Analytical Chemist.

O.M. Watson, Jno. C., Farwell Bleachery, Laurence, Mass., U.S.A., Printworks Chemist.

O.M. Watt, A., c/o Macfie and Sons, 34, Moorfields, Liverpool, Sugar Works Chemist.

1901. Watt, Francis L., 10, Northcote Chambers, Reiby Lane, Circular Quay, Sydney, N.S.W., Australia, Analytical Chemist.

1906. Watt, Dr. H. E., Blandfield Chemical Works, Wheatfield Road, Edinburgh, Chemist.

1893. Watts, Jno. Isaac, Fairleigh, Hartford, Cheshire, Alkali Works Manager.

1908. Watts, Jno. Wm., Newcastle Tar Works, Blaydon-on-Tyne, Manager.

1910. Watts, Reginald H. Pole, 57, Leagrave Road, Luton, Beds., Research Chemist.

1907. Waumsley, Harry, 12, Rowhill Mansions, Clapton, N.E., Chemical Engineer.

1903. Wayland, Wm. A., 12, Albert Road, Brockley, S.E., Manufacturing Chemist.

1906. Webb, Frank H., 7, Dustin Street, Haverhill, Mass., U.S.A., Chemist.

1905. Webber, W. J., 40, Central Street, Boston, Mass., U.S.A., Manufacturing Chemist.

1912. Weber, Dr. Max G., 151, Water Street, Perth Amboy, N.Y., U.S.A., Works Manager.

1901. Webster. Geo. J., P.O. Box 1003, Marquette, Mich., U.S.A.. Secretary.

1902. Webster, Jno., Laboratory of Pathological Chemistry, St. Mary's Hospital, London, W., Analyst.

1906. Weddell. George, 20, Grainger Street West. Newcastle-on-Tyne, Manufacturing Chemist.

1904. Wedekind, Rud., Uerdingen, Niederrhein, Germany, Manufacturer of Alizarin and Bichromates.

1897. Wedge, Utley, Pennsylvania Salt Manufacturing Co., Philadelphia, Pa., U.S.A.. Chemist.

1902. Weed, Hy. T., 176, Prospect Park West, Brooklyn, N.Y., U.S.A., Teacher of Chemistry.

1893. Weeks, H. B., 2, Infield Park Road, Barrow-in-Furness, Analytical Chemist.

1904. Weil, Jacob A., c/o The Power Gas Corporation, Ltd., Stockton-on-Tees, Chemist.

1910. Weinberg, Dr. Arthur von, "Buchenrode," Forsthaus-strasse, Frankfurt a/M, Germany, Dyestuff and Chemical Manufacturer.

1906. Weir, James, c/o Imperial Varnish and Color Co., 6—24, Morse Street, Toronto, Canada, Chemist.

1902. Weiskopf, Dr. Erich, Authors' Club, Whitehall Court, London, S.W., Works Manager.

1910. Weiss, John M., c/o Barrett Manufacturing Co., Research Dept., Hudson Heights, N.J., U.S.A., Chemist.

1908. Weissmüller, Edward F., Spring Lodge, Helsby, Cheshire, Chemist.

1905. Weissmüller, Ernest C., Craig Leith, Overton, Frodsham, Cheshire, Research Chemist.

1910. Welch, Bertie M., 80, Hunter Street, Sydney, N.S.W., Australia. Assayer.

1912. Weld, Fred. C., 263, Fairmount Street, Lowell, Mass., U.S.A., Analytical Chemist.

1899. Weldon, Leonard E., Hadleigh, Alma Street, Sherwood Rise, Nottingham, Dyer.

1903. Wellcome, Henry S., Snow Hill Buildings, London, E.C., Manufacturing Chemist.

1912. Wells, Jas. H., 18, Alwyne Place, Canonbury, London, N., Metallurgist.

1885. Welsh, Jas., Standard Mills, Ferguson Road, Bombay, India, Printworks Manager.

1890. Welsh, Thos. L., 3, Prince's Gardens, Dowanhill, Glasgow, Analytical Chemist.

O.M. Welsh, W., Holt Town Oil Works, Manchester.

1905. Welt, Dr. Ida, 101, West 109th Street, New York City, U.S.A., Chemist.

1906. Wenger, Francis E., Clivedon, Wolstanton, Stoke-on-Trent, Ceramic Colour Manufacturer.

1909. Wescott, J. P., jr., 55, Washington Park, Newton ville, Mass., U.S.A.. Manager, Atlas Chemical Co.

1903. Wesener, Dr. John A., 31, North State Street, Chicago, Ill., U.S.A., Consulting Chemist.

1889. Wesson, D., 111, South Mountain Avenue, Montclair, N.J., U.S.A., Cotton-oil Expert.

1908. West, Chas. A., c/o American Camphor Refining Co., 14, Fulton Street, Boston, Mass., U.S.A., President.

1903. West, Leonard, Selworthy, Quarndon, Derby, Manufacturing Chemist.

1909. West, Percy. C. H. 40 Museum Street, London, W.C., Analytical Chemist.

1900. Westenfelder, B. D., 1414, Race Street, Cincinnati, Ohio, U.S.A., Chemist.

1885. Westmoreland, J. W., 12, Arthington Terrace, Hunslet, Leeds, Metallurgical Chemist.

1898. Weston, David B., Sharon, Mass., U.S.A., Chemist.

1894. Weston, Robt. S., 14, Beacon Street, Boston, Mass., U.S.A., Chemist and Bacteriologist.

1885. Weston, Wm., 2, Ulundi Road, Blackheath, S.E., Analytical Chemist.

1890. Wetter, Jasper, Room 23, Holborn Hall, Gray's Inn Road, London, W.C., Patent Agent.

1912. Weyman, Geoffrey, 70, Manor House Road, Jesmond, Newcastle-on-Tyne, Technical Chemist.

O.M. Whalley, L. J. de, 18, Brandram Road, Lee, S.E., Sugar Chemist.
1909. Wharton, Fredk. M., c/o The New Explosives Co., Ltd., Stowmarket, Suffolk, Chemist.
1908. Wheaton, H. J., Spondon, near Derby, Chemical Engineer.
1909. Wheeler, Edward, 144, Earlsdon Avenue, Coventry, Demonstrator of Chemistry.
1898. Wheeler, Dr. Edwd. J., 79, Chapel Street, Albany, N.Y., U.S.A., Analytical Chemist.
1903. Wheeler, Ernest, 4, Fairfield Terrace, Higher Openshaw, Manchester, Metallurgical Chemist.
1906. Wheeler, Frank G., 683, Harris Street, Appleton, Wis., U.S.A., Chemist.
1907. Wheeler, R. Vernon, Home Office Experimental Station, Eskmeals, Cumberland, Chemist.
1912. Wheeler, Thorne L., c/o Edible Products Co., 156—186, East 22nd Street, Bayonne, N.J., U.S.A., Chemist.
1895. Wheelwright, Dr. E. W., 14, Carisbrooke Road, Edgbaston, Birmingham.
1909. Whiffen, G. Goodman, Lombard Road, Battersea, London, S.W., Chemical Engineer.
O.M. Whiffen, Thos. J., Cerris House, West Hill, Putney, S.W., Manufacturing Chemist.
O.M. Whiffen, W. G., Lombard Road, Battersea, London, S.W., Manufacturing Chemist.
1899. Whitaker, Milton C., Columbia University, New York City, U.S.A., Chemist.
1895. Whitaker, Thos., Aire Vale Dye Works, Newlay, near Leeds, Dyer.
O.M. Whitaker, Thorpe, (Journals) Bradford Dyers' Association, Ltd., and 35, Pemberton Drive, Bradford, Yorks, Dyer's Chemist.
1893. White, Arthur F., 2, Melbourne Grove, Thornbury, Bradford, Yorks, Manufacturing Druggist.
1901. White, H. Graham, 28, Brancote Road, Oxton, Birkenhead, Works Chemist.
1898. White, Jno., County Offices, St. Mary's Gate, Derby, Public Analyst to County of Derby.
1911. White, John W., c/o E.C. Powder Co., Green Street Green, Dartford, Kent, Works Chemist.
O.M. White, Paul T., Hortonfield House, West Drayton, Chemical Manufacturer.
1910. White, P. Winzar, Mayfield, Hayes, Middlesex, Manufacturing Chemist.
1911. White, Walter W., c/o Citro Chemical Co., Maywood, N.J., U.S.A., Secretary and Manager.
1912. Whitehead, Charles E., 20, Albion Road, Chesterfield, Derbyshire, Chemist.
1903. Whitehouse, P. L., 16, Lombard Street, West Bromwich, Staffordshire, Oil Chemist.
1906. Whiteley, C. E., 21, Brudenell View, Leeds, Demonstrator of Chemistry.
1885. Whiteley, R. Lloyd, The Institute, West Bromwich, Staffordshire, Principal.
1892. Whiteside, Jno. L., 376, St. Helen's Road, Bolton-le-Moors, Chemical Lecturer.
1911. Whitley, George, jr., c/o Ridley, Whitley, and Co., Ltd., Angel Road Works, Edmonton, N., Linoleum Manufacturer.
1912. Whitney, Wm. L., c/o U.S. Graphite Co., Saginaw, Mich., U.S.A., Chemist.
1885. Whittaker, C. J., Somerville, Fairhaven, Lytham, Lancashire, Chemical Engineer.
1904. Whittier, Charles T., 78, Brinkerhoff Street, Jersey City, N.J., U.S.A., Manager.
1901. Whitton, Jas. T., c/o Nobel's Explosives Co., Ltd., Ardeer, Stevenston, Chemist.
1884. Whowell, F., Croich Hey, Tottington, Bury, Lancs, Bleacher.
1910. Whymper, R., St. Clare's, St. Mary's Road, Ditton Hill, Surbiton, Chemist.
1899. Wiarda, Jno. C., 259–273, Green Street, Brooklyn, N.Y., U.S.A., Manufacturing Chemist.
1913. Wickenden, Leonard, c/o West Virginia Paper and Pulp Co., 521, West 23rd Street, New York City, U.S.A., Research Chemist.
1908. Wickes, Clarence S., 28, Franklin Avenue, Merchantville, N.J., U.S.A., Factory Superintendent.
1905. Widmann, Eugene A., 588, 5th Street, Brooklyn, N.Y., U.S.A., Dyestuff Merchant.
1904. Wieler, Eric E., Northern Assurance Buildings, Albert Square, Manchester, Chemical Merchant.
1906. Wiffen, Henry J., 17, Albany Road, Manor Park, Essex, Manufacturing Chemist.
1883. Wiggin, W. W., 55, George Street Parade, Birmingham, Nickel Refiner.
1897. Wigglesworth, R., 25, Broad Street, New York City, U.S.A., Manufacturing Chemist.
O.M. Wightman, Charles, Springfield, Stevenage, Herts.
1913. Wigner, J. H., Warddykes, Frodsham, Cheshire, Works Chemist.
1906. Wikner, Sigurd A., "Lynton," Kingsbury Road, Gravelly Hill, Birmingham, Tar Works Chemist.
1899. Wild, Roland C., The Grange, New Eltham, Kent, Analytical Chemist.
1893. Wilder, F. L., 10, Forest Rise, Walthamstow, Essex, Assayer.
1902. Wilder, Salmon W., jun., 33, Broad Street, Boston, Mass., U.S.A., Treasurer.
1911. Wildt, Dr. Edwin, c/o Badische Anilin und Soda Fabrik, Ludwigshafen a/Rhein, Germany, Technical Chemist.
1912. Wiley, Samuel W., 15, South Gay Street, Baltimore, Md., U.S.A., Analytical Chemist.
1906. Wilke, Wm., 86, Norwood Avenue, Buffalo, N.Y., U.S.A., Chemical Engineer.
1899. Wilkens, H. A. J., 60, Broadway, New York City, U.S.A., Mining Engineer.
1903. Wilkie, Jno. M., 38, South Road, West Bridgford, Nottingham, Analytical Chemist.
1885. Wilkin, Sir Walter, K.C.M.G., Appold Street, Finsbury, E.C., Yeast Manufacturer.
1895. Wilkins, Charles, 40, Church Lane, Hornsey, N., Manufacturing Perfumer.
1911. Wilkinson, Frank, West Lodge, Handsworth, near Sheffield, Chemical Manufacturer.
1904. Wilkinson, Prof. J. A., South African School of Mines and Technology, P.O. Box 1176, Johannesburg, Transvaal, Professor of Chemistry.
1886. Wilkinson, J. B., Tong Street, Dudley Hill, Bradford, Yorks, Chemical Manufacturer.
1903. Willard, C. T., c/o The Singer Manufacturing Co., Elizabethport, N.J., U.S.A., Chemist.
1893. Willcox, Benjamin, 47, Lincoln's Inn Fields, London, W.C., Patent Agent.
1911. Willcox, Stuart J., 46, Mulgrave Street, Liverpool, Chemist.
1903. Williams, Chas E., Thornhayes, Sleaford, Seed Crusher.
1895. Williams, David T., 42, Finsbury Square, London, E.C., Chemist and Assayer.
1912. Williams, Egbert R., c/o Northern Aluminium Co., Shawinigan Falls, P.Q., Canada, Chemist.
1891. Williams, Henry J., 161, Tremont Street, Boston, Mass., U.S.A., Chemical Engineer.
1908. Williams, Herbert E., 28, Cranston Road, Forest Hill, S.E., Chemist.
1904. Williams, Jno. T., 815, Madison Avenue, New York City, U.S.A.
1913. Williams, Jos. H., 49, Addison Road, Snaresbrook, Essex, Works Chemist.
1904. Williams, Naboth, 28, Rolleston Street, Warrington, Technical Chemist.
1902. Williams, Percy, 94, Telford Avenue, Streatham Hill, S.W., Chemist.
1885. Williams, Rowland, 79, Queen Square, Lancaster, Analytical Chemist.
1912. Williams, Samuel B., Penelvan, Roskear, Camborne, Cornwall, Metallurgist.
1900. Williams, Saml. H., Glastonbury, Conn., U.S.A., Soap Manufacturer.
1903. Williams, S. M., 269, Springdale Avenue East Orange, N.J., U.S.A., Chemist.
1885. Williams, T. Howell. *See* Idr[illegible] T. H. W.
1884. Williams, Prof. W. Carleton, Broomgrove, Goring-on-Thames, Professor of Chemistry.
1902. Williams, Walter Scott, 150, Mystic Street, West Medford, Mass. U.S.A., Textile Engineer.

1887. Williams. W. Collingwood, 36, Dansie Street, Liverpool, Analytical Chemist.
O.M. Williams, W. J., 5004, Griscom Street, Frankford, Philadelphia, Pa., U.S.A., Analytical Chemist.
1894. Williamson, J. Alex., The Croft, Chase Court Gardens, Enfield, N., Analytical Chemist.
1911. Williamson, John, jun., Alne Hill, Camp Road, Maryport, Cumberland, Tanner.
O.M. Williamson, Robt., Low Walker, Newcastle-on-Tyne, Technical Chemist.
1903. Wills, J. Lainson, c/o Otto F. Stifel's Union Brewing Co., Gravois and Michigan Avenues, St. Louis, Mo., U.S.A., Technical and Brewing Chemist.
1905. Wills, Wm. H., 23, Willow Street, Waltham, Mass., U.S.A., Dyer.
1888. Wilson, Cecil H., c/o Sheffield Smelting Co., Ltd., Royds Mills Street, Sheffield, Chemist.
1888. Wilson, Dr. David, Carbeth, Killearn, by Glasgow.
1910. Wilson, Dr. Forsyth J., Royal Technical College, Glasgow, Lecturer.
1885. Wilson, Frank, 7, Bedford Square, London, W.C., Brewer.
O.M. Wilson, G. E., The Chemical Works, Oldbury, near Birmingham, Chemical Manufacturer.
1902. Wilson, Geo. W., Viaduct House, Dinting, near Manchester, Works Chemist.
1899. Wilson, Gordon, Benallan, Kirkintilloch, and (Journals) Apartado 92, Zacatecas, Mexico, Chemist and Assayer.
1886. Wilson, Jno., Tyneside, 381, Hagley Road, Birmingham, Technical Chemist.
1896. Wilson, Jno., "Lynton," Dingle Hill, Colwyn Bay, North Wales, Chemical Engineer.
1909. Wilson, Jno., Battersea Polytechnic, London, S.W., Head of Chemical Dept.
1905. Wilson, J. E., c/o General Chemical Co., 25, Broad Street, New York City, U.S.A., Chemical Salesman.
1906. Wilson, J. Murray, c/o Canadian Explosives, Ltd., Transportation Building, Montreal, Canada, Technical Chemist.
1902. Wilson, Leonard P., 8, Chester Street, Coventry, Technical Chemist.
1910. Wilson, Leslie, West Bank, Doxey, near Stafford.
O.M. Wilson, R. H., Egglecliffe P.O., Co. Durham, Chemical Manufacturer.
1912. Wilson, S. Siddons, 154, Burges Road, East Ham, Essex, Analytical Chemist.
1909. Wilson, Wm. J., 12, Vicarage Park, Plumstead, Kent, Chemist.
1908. Wilson, William James, Tirohanga, North End Road, Devonport, Auckland, New Zealand, Consulting Cement Engineer.
1890. Wilson, W. W., Dalmonach House, Alexandria, Dumbartonshire, Analytical Chemist.
1884. Wilton, Thos., Winsor House, Beckton, E., Tar Works Manager.
1912. Windsor, P. L., Library, University of Illinois, Urbana, Ill., U.S.A., Librarian.
1913. Windsor-Richards, W., c/o Allen West and Co., Ltd., Lewes Road, Brighton, Chemist.
1892. Wingfield, T. R., 12, Suffolk Road, Bournemouth West, Brewer.
O.M. Wingham, A., 57, Victoria Road South, Southsea, Hants, Metallurgical Chemist.
1908. Winkler, Hermann, Bockenheimer Anlage 43, Frankfurt a/Main, Germany, Merchant.
O.M. Winser, P. J., Heath House, Knutsford, Cheshire, Consulting Chemist.
1907. Winsloe, Louis S., 1, Booth Street, Manchester, Manufacturing Chemist.
1892. Winstanley, W. Hy., Birch House, Cheadle Hulme, Cheshire, Technical Chemist.
1886. Winstone, E. H., Members' Mansions, 36, Victoria Street, London, S.W., Ink Manufacturer.
1907. Winther, [illegible] A., Chemische Fabrik Griesheim-Elektron, Werk Oehler, Offenbach a/Main, Germany, Chemist.
1892. Wirtz, Dr. Quirin, 28, Great Ormond Street, London, W.C., Consulting Chemist.
1889. Wishart, Jno., Oakbank Oil Co., Ltd., 29, St. Vincent Place, Glasgow, General Manager.
1902. Withers, Prof. W. A., State A. and M. College, West Raleigh, N.C., U.S.A., Professor of Chemistry.
1906. Withey, Wm. S., Burry Port, South Wales, Chemist.
O.M. Witt, Dr. Otto N., Ebereschenallee 10, Westend, bei Berlin, Professor of Chemistry.
1903. Wolf, Jacques, c/o Jacques Wolf and Co., Passaic, N.J., U.S.A., Manufacturing Chemist.
1912. Wolff, Dr. Salamon, c/o Messrs. Mather and Platt, Park Works, Manchester, Chemical Engineer.
1911. Wollaston, T. Roland, Dirleton House, Priory Road, Sale, Cheshire, Consulting Engineer.
1903. Wolton, Wm. R., c/o Joseph Fison and Co., Ltd., Ipswich, Manager.
1914. Wood, A. S., c/o Messrs. Levinstein, Ltd., Blackley, Manchester, Works Chemist.
1906. Wood, E. Escott. Hurricane House, Brymbo, near Wrexham, North Wales, Chemist and Metallurgist.
1900. Wood, Frank, Ardsley House, near Barnsley, Yorks, Assistant Manager (Glass Works).
1901. Wood, Frank S., 12, Carlton Avenue, Hornsea, East Yorks., Cement Works Chemist.
1909. Wood, Hubert R., c/o Fenner and Alder and Co., Fenner's Wharf, Millwall, E., Works Chemist.
1887. Wood, Jos. T., 62, Park Road, Nottingham, Tanner.
1906. Woodall, Sir Corbett, Palace Chambers, Westminster, London, S.W., Civil Engineer.
O.M. Woodcock, R. C., c/o Sanitas Co., Ltd., Locksley Street, Limehouse, London, E., Chemist.
1910. Woodhead, Arthur E., Dyeing Dept., The University, Leeds, Research Student.
1884. Woodhead, Jas., Inglewood, Slaithwaite, near Huddersfield, Tar Distiller.
1900. Woodrow, John, 84, Harpenden Road, Manor Park, E., Chemist.
1906. Woodward, Horace A., Cowell Avenue, West Orange, N.J., U.S.A., Chemist.
1904. Woolcott, Geo. H., Lady's Well Brewery, Cork, Ireland, Brewer's Chemist.
1914. Wooldridge, H. B., Tottenham Brewery, Tottenham, N., Brewer.
O.M. Woolley, G. S., Victoria Bridge, Manchester, Pharmaceutical Chemist.
1905. Woore, N. L., c/o South Australian Gas Co., Brompton, Adelaide, South Australia, Works Chemist.
1901. Worden, Edw. C., Millburn, N.J., U.S.A., Manufacturing Chemist
1909. Work, Charles O., 22, Cambridge Road, Great Crosby, Liverpool, Analytical Chemist.
1914. Worley, Prof. Fred. P., University College, Auckland, New Zealand, Prof. of Chemistry.
O.M. Worrall, H., Culmington House, Stanton Lacey, Ludlow, Dyer.
1903. Worstall, Robt. A., 21, North La Salle Street, Chicago, Ill., U.S.A., Paint and Varnish Specialist.
1900. Worthington, Arthur, Lynwood, Great Lever, Bolton, Chemist and Manager.
1896. Wrampelmeier, T. J., 565, Monadnock Building, San Francisco, Cal., U.S.A., Chemist.
O.M. Wray, O. J. P., Hazlemere, Coleraine Road, Blackheath, S.E., Technical Chemist.
1904. Wright, Allister M., Box 617, G.P.O., Christchurch, N.Z., Chemist (Christchurch Meat Co.).
1912. Wright, Arthur, 111, Broadway, New York City, U.S.A., Lawyer.
1895. Wright, Arthur C., c/o Turner, Morrison, and Co., 6, Lyons Range, Calcutta, India, Chemist.
1908. Wright, C. Harold, Government Laboratory, Port of Spain, Trinidad, B.W.I., and (Journal) 3, Virginia Terrace, Leeds, Analytical Chemist.
1904. Wright, Chas. L., 123, South Madison Avenue, La Grange, Ill., U.S.A., Chemical Engineer.
1901. Wright, Harold E., c/o Sir B. Samuelson and Co., Ltd., Middlesbrough, Chemist.
1907. Wright, John Henry, 16, Norwood Avenue, Shipley, Yorks. Technical Chemist.
1885. Wright, Jos., 19, Arboretum Street, Nottingham Lace Dresser.

O.M. Wright, L. T., Junior Constitutional Club, Piccadilly, London, W., Chemical Engineer.
1910. Wright, Robert, 122, York Street, Jarrow-on-Tyne, Blast Furnace Manager.
1911. Wright, Robt., c/o Thos. Adams, Ltd., Sherwood Hill Works, Nottingham, Bleacher and Dyer.
1900. Wright, Walter J., 59, Stone Street, Faversham Kent, Chief Chemist (Cotton Powder Co.).
1890. Wulfling, Dr. Charles, Hönningen a/Rhein, Germany, Technical Chemist.
1907. Würster, Oscar H., c/o Lever Bros., Ltd., Toronto, Canada. Soap Works Chemist.
1890. Wyatt, Dr. Francis, 402, West 23rd Street, New York City, U.S.A., Consulting Chemist.
1905. Wyer, Malcolm G., The Library, State University, Iowa City, Iowa, U.S.A., Librarian.
O.M. Wyld, Jno., The Avenue, Lidgett Park, Roundhay, Leeds, Chemical Works Manager.
1908. Wyler, Dr. Max, c/o Levinstein, Ltd., Blackley, Manchester, Manufacturing Chemist.
1906. Wynne, Prof. W. Palmer, F.R.S., The University, Sheffield, and (Journals) 17, Taptonville Road, Sheffield, Professor of Chemistry.

Y

1901. Yardley, Frank, c/o Henry Jutson and Sons, Liverpool Street, Birmingham, Chemical Manufacturer.
1897. Yates, W. H., Durley Park, Keynsham, Bristol, Technical Chemist.
1913. Yeomans, Wm. W., 40, Alleghany Street, Buffalo, N.Y., U.S.A., Chemist.
1906. Yerkes, Leonard A., c/o Jos. Bancroft and Sons Co., Wilmington, Del., U.S.A., Bleacher and Finisher.
1898. Yetton, Thos., 86, Bow Road, London, E., Consulting Distiller's Chemist.
1894. Yocum, Dr. Jno. H., 325, Academy Street, Newark, N.J., U.S.A., Chemist.
1886. Yoshida, Prof. H., Imperial University of Kyoto, Kyoto, Japan, Professor of Chemistry.
1900. Yoshitake, E., Nishihara Machi, Koishikawa, Tokyo, Japan, Chemist.
1885. Young, Alfred C., 17, Vicar's Hill, Lewisham, S.E.
1885. Young, Brougham, 2A, Sigdon Road, Dalston, N.E., Analytical Chemist.
